

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

Published by the American Chemical Society, Easton, Pa.

Entered as Second-class Matter at the Post-Office, Easton, Pa.

Communications for the Editor should be addressed to E. J. Crane, Ohio State
versity, Columbus, Ohio.

The Council have voted that no claims for copies lost in the mails can be allo
unless such claim is received within "sixty days" of the date of issue, nor if du
failure to give sufficient notice of change of address. Charles L. Parsons, Secretary.

Remittances for annual membership dues or for subscriptions, changes of add
orders for subscriptions or back numbers, claims for missing numbers and all mat
intended for the Proceedings should be sent to the Secretary, Charles L. Parsons,
808, Washington, D. C.

Secretary's Office, Box 505, Washington, D. C.
Eachenbach Printing Company, Easton, Pa.

The American Chemical Society

The Board of Directors of the American Chemical Society has fixed the following schedule of prices for its publications:

Subscription Rates

Journal American Chemical Society.....	\$ 6.00
Chemical Abstracts.....	6.00
Jour. Industrial and Engineering Chemistry.....	6.00
Two Journals to same address.....	10.20
All three Journals to same address.....	12.60

Back Numbers and Volumes

	To Members	To Non-members
Single Numbers: J. A. C. S.; J. I. E. Chem. or Chem. Abs....	0.50	0.60
Proceedings, Vol. 1 (1876); Vol. 2 (1877).....	2.00	2.50
Back volumes { J. Am. Chem. Soc., Vols. 1-16 inclusive, each....	4.00	5.00
J. Am. Chem. Soc., Vols. 17-37 inclusive, each....	5.00	6.00
Chem. Abs., Vol. 1, 2, 3 or 5 complete, each.....	10.00	12.00
Chem. Abs., Vol. 4, 6, 7, 8 or 9 complete, each....	5.00	6.00
Index to Vols. 1-20, J. Am. Chem. Soc.....	0.50	0.75
Index to Chem. Abstracts, Vol. 1, 2, 3, 4, 5, 6 or 7.....	1.00	1.00
Jour. Ind. and Eng. Chem., Vols. 1-7.....	5.00	6.00
Foreign Postage, each Journal 75c.; Chemical Abstracts, \$1.00 a year		

Special Discounts to Newsdealers, Libraries and Institutions of Learning

Complete sets, Vols. 1 to 35, of the Journal; Proceedings, Vols. 1 and 2, and Vols. 1 to 7 of Chemical Abstracts may be had of the Secretary.

The following numbers can be furnished only in complete sets, viz: J. Am. Chem. Soc., 17 (1895), 1 and 8; 18, 5; 19, 1; 20, 3; 22, 3.

Besides the above, the following numbers can be furnished only in complete volumes, viz: J. Am. Chem. Soc., 26, 4; 29 (1907), 4; 30 (1908), 2, 3, 4, 5, 6 and 7; 33, 3, 4 and 9; 34, 9, 10 and 11; Chemical Abstracts, 1 (1907), 3, 12, 13, 14, 15 and 16; 2 (1908), 1 and 2; 5, no numbers except 1, 4 and 6; Jour. Ind. and Eng. Chem., 1, only No. 11; 3, Nos. 3 and 12; 4, Nos. 3, 4, 5, 7 and 10; 5, No. 1.

Advance payment is required and should be made by check or money order only. Stamps not wanted.

The Council has voted that the Secretary shall honor claims for non-receipt of publications only if made within sixty days of their issue. Claimants must also directly state that the publication was not delivered at their recorded address. "Missing from files" is no proof of non-receipt.

The Society will not be responsible for loss due to change of address unless notification is received one week in advance of issue.

Members or subscribers desiring their Journals or Abstracts forwarded from an old address should always notify their Postmaster and leave necessary postage.

The names of members and subscribers, whose Journals or Chemical Abstracts cannot be delivered by the Post-Office Department, will be cut off the mailing list at once, and will not be restored until correct addresses have been furnished.

In the absence of other information, the notices of change of address received from the Post-Office Department will be considered as correct, and the mailing list changed accordingly.

All communications should be addressed to

CHARLES L. PARSONS, Secretary,

Box 505, Washington, D. C.

PATENTS

Abstracts of patents are included under the appropriate divisions of the journal: those on organic compounds, unless they pertain especially to some other division, are under Pharmaceutical Chemistry. The abstracts of U. S. patents are prepared by Earl T. Ragan, those of Canadian patents by Russell S. Smart, of Fetherstonhaugh & Smart, Ottawa (50 Queen St.), and all others by O. D. Swett. Most German patents are prepared, with permission, from the abstracts in *Chemiker-Zeitung* and Italian patents from those in *Annali di chimica applicata*. All other patents are obtained direct from the specifications.

Copies of any patent may be obtained for: United States, 5 cents, sent to the Patent Office, Washington, D. C.; French, one franc, sent to L'Imprimerie Nationale, 87 rue de Vieille du Temple, Paris; German, one mark, sent to the Patent Office, Berlin; British, eight pence, sent to Patent Office, London (extra postage outside United Kingdom); Austrian, write to the Patent Office, Vienna; Danish, write to the Patent Office, Copenhagen; Norwegian, 1 crown, Patent Office, Christiania; Swedish, 1 crown, Patent Office, Stockholm. Of Canadian patents, manuscript copies only are obtainable. They may be secured from Fetherstonhaugh & Smart, or the Commissioner of Patents direct. Estimates of cost may be obtained in advance.

In ordering a copy of a patent, the number of the patent, name of the patentee, and subject of the invention should be stated.

CHEMICAL ABSTRACTS

Vol. 10.

JANUARY 10, 1916.

No. 1

I. APPARATUS.

L. C. JONES.

The Inertoid: an automatic apparatus for carrying out chemical reactions in inert atmospheres. RODOLFO FRITSCH. Vienna. *Chem. Ztg.* 39, 743(1915).—A wide-mouth dropping funnel with safety-tube discharge connected to a larger tube through a rubber stopper is mounted on a stand, the lower end of the larger tube ending in a beaker, or, if the products of the reaction are volatile or affected by the air, in a wide-mouth flask with condenser. Near the top the large tube branches, and 1 hole in a 3-hole stopper in the mouth of the funnel carries a tube for filling the app. with inert gas. This tube also branches and 1 arm connects with the branch on the large tube. The middle hole in the stopper carries a glass rod with a round flat inner end. The 3rd hole carries an exhaust tube. The reacting substances, one in a closed glass tube, are placed in the app. which is filled with inert gas and the reaction started by breaking the glass tube with the glass rod.

J. H. MOORE.

A safe automatic gas valve for preserving reduced solutions. PAUL VERBEEK. *Chem. Ztg.* 39, 840(1915).—Three Erlenmeyer flasks of 50-75 cc. capacity are connected with bent tubes, the tube connecting the 2nd and 3rd flasks extending nearly to the bottom of each. The 2nd hole in the stopper of the 1st flask carries a dropping funnel of 100-50 cc. capacity, with glass cock and narrow stem. The 2nd hole of the stopper in the 3rd flask carries a Kjeldahl trap connected with a tube reaching nearly to the surface of the reduced soln. in a larger flask. The 2nd hole in the stopper of this flask carries a tube and screw pinchcock to regulate the flow of CO_2 or other inert gas. The funnel contains HCl (1:1), the 1st and 3rd flasks contain broken limestone and the 2nd contains H_2O . After displacing the air with CO_2 the soln. is reduced and the pinch-cock closed, the cock in the funnel stem being left open to equalize the pressure as the soln. cools.

J. H. MOORE.

Improved form of gas washing bottle. F. R. v. BICHOWSKY AND H. STORCH. *J. Am. Chem. Soc.* 37, 2695-6(1915).—The app. consists of an ordinary bottle, or a square medicine bottle, fitted up as a common wash bottle which is laid on its side, and has a small side tube at C. The gas enters the bottle through the lower tube and forms bubbles at the bend G in the tube A. The advantages are: efficient washing, slight pressure head required, and negligible amt. of spray formed. Another model is shown in which the cork is replaced by a glass seal; it is for liquids which would corrode the stopper or absorb impurities from it.

E. B. MILLARD.

U-tube carbon dioxide indicator. E. A. CUNNINGHAM. *Iron Age* 96, 870-2 (1915).—App. consists of a chamber filled with KOH to which is attached a Hg gage for measuring diminution of pressure caused by absorption of CO_2 . A motor-driven cam arrangement opens and closes the various valves and records the analyses on a chart. The analyses made by the instrument agree with those by a Hempel app. to 0.5%.

F. L. GROVER. ✓

Evaporation of liquids at low temperatures. B. C. P. JANSEN. *Chem. Weekblad* 12, 482-3(1915).—An app. in which a small elec. fan pushes the air through a hot wire coil has been successfully used for the evapn. of liquids at low temps. J. T. FLOHL.

Standardization of the freezing-point thermometer. N. SCHOORL. *Chem. Weekblad* 12, 222-5(1915).—S. suggests the use of eutectic mixts. for the standardization of f. p. thermometers. The eutectic mixts. $\text{KNO}_3\text{-H}_2\text{O}$ and $\text{Ba}(\text{NO}_3)_2\text{-H}_2\text{O}$ are most useful as their eutectics lie near the f. p. of water, that of the former being -2.86° and that of the latter -0.71° . Prep. solns. of KNO_3 1:4 and $\text{Ba}(\text{NO}_3)_2$ 1:8 by heating slowly. These solns. are cooled in cold H_2O while vigorously shaken until crystd. and may be kept in stoppered bottles. Whenever big crystals appear, heat the mixt. slowly and cool as above. J. T. FLOHL.

A vacuum furnace for the measurement of small dissociation pressures. R. B. SOSMAN AND J. C. HOSTETTER. *Z. Elektrochem.* 21, 495-9(1915); see *C. A.* 9, 1557. E. H.

Automatic vacuum pump. OTTO MAASS. *J. Am. Chem. Soc.* 37, 2654-6(1915).—An arrangement of a Töpler pump with Antropoff's modification (cf. *C. A.* 5, 402) which, in conjunction with an aspirator, works automatically. The arrangement does not involve the use of a spring or valve, is simple to make, and can safely be allowed to run for an indefinite period. A portion of the pump was described by Johnson. Cf. *C. A.* 6, 2868. E. B. MILLARD.

Electrically operated vacuum pump. ANON. *Elec. World* 66, 1109-10(1915).—A high vacuum pump of the oscillating-ring type, consisting of 4 parts, the body, impeller, cover and shaft, is described. Moisture and liquid will pass through it. Displacement of free air per min. is 930 cu. in.; the max. vacuum obtained is 0.25 mm. It is being manufd. by the May-Nelson Mfg. Co., Washington, D. C. Diagrams are given. I. C. MATTHEWS.

Making a chemists' balance. F. W. SALMON. *Power* 42, 617-9(1915).—Describes how a balance, such as is used in coal analysis, may be cheaply and easily constructed. Hard maple and hard white cedar are used for the base and beam and smoothly ground-knife files for knife edges. C. G. F.

Viscosimeters. R. F. MACMICHAEL. *Met. Chem. Eng.* 13, 767-9(1915).—All viscosimeters operate on one of two general principles: (1) the time required to produce a definite relative movement of the fluid particles under a given force; (2) the force required to produce a definite relative movement of the fluid particles in a given time. The most prominent examples of instruments based on the second principle are those of Couette, Clark and MacMichael. In each of these instruments a cylinder or disk is suspended in a cup of fluid and either the disk or the cup is revolved, and the torsional force noted. M. points out the advantages of the MacMichael viscosimeter over the other instruments of this class as follows: In the MacMichael viscosimeter, the force exerted by the rotation of the fluid itself on the stationary member is measured. The construction is simple and durable. The fluid to be tested is heated in place, no other heating device being required. The temp. during the test may be controlled within a small fraction of 1°F . The readings are in degrees of angular deflection, 300 degrees to the circle, designated as deg. M. The practical working unit is $1/1000$ of the absolute unit. As H_2O at 20°C . has exactly $1/100$ of the absolute unit of viscosity, H_2O at this temp. reads 10 deg. M. Readings are taken directly from the dial, no intermediate calcn. being required. As the time required for a reading is extremely short detns. may be made of suspensions, such as clay slips, which settle rapidly. Colloidal solns. like glues, gums, starch solns., gelatin, etc., may also be handled successfully. Likewise, the viscosity of complicated mixts. such as catsup, food materials,

etc., may be readily detd. Straining is unnecessary as small particles of foreign material do not in any way affect the accuracy of the detn. The instrument with its thermometer and pipet is complete in itself. Skilled labor is not required in its use. The personal equation is small. C. A. NOWAK.

Making and using thermocouples. F. G. COBURN. *Am. Machinist* 43, 643-4 (1915).—C. discusses the importance of using wires of uniform compn. throughout, the construction of Pt-Rh and of base metal couples, and maintenance of cold junctions. C. G. F.

Electrical heating and the Schoop metal spraying process. LACH. *Elektrotechn. Z.* 36, 270-3(1915).—New elec. heating units are described and illustrated. With the aid of the Schoop "gun" a thin ribbon of metal is squirted on to unglazed porcelain, clay, etc., tubes or plates. For high temp. heaters a Cr-Ni alloy is "squirted;" for lower temp., German silver or a similar alloy is used. C. G. F.

Filter. J. J. LASSEN and V. F. HJORT. *Brit.*, 16,185, July 7, 1914. A filter comprising a series of filtering layers through which the liquid passes upwards is fitted with a longitudinal conduit or trough common to each of the filtering compartments, and with means for directing the liquid into the trough to throw any desired filtering layer out of action.

Blowpipe burner. CHEM. FABRIK GRIESHEIM-ELEKTRON. *Brit.*, 15,763, July 1, 1914. A blowpipe burner, of the kind in which the O supply pipe is arranged coaxially with the mixed gas and O pipe and the cutting-O supply is taken by way of a sep. conduit branching from the main O supply pipe, is constructed with the terminal of the main O supply pipe arranged in a closed pressure chamber near the outlet for the heating gas pipe, and the outlet from this chamber for the cutting-O supply as remote as possible from the main supply pipe.

Apparatus for drying and cooling granular material. TOPF & SOEHNE. *Brit.*, 3,375, Feb. 9, 1914.

Mixing liquids. B. GOLDMAN and GALVINISCHE METALL-PAPIER FABRIK AKT.-GES. *Brit.*, 24,588, Oct. 29, 1913. The app. comprizes rotary stirrers co-acting with wings or blades extending inwards from the walls of the vessel; the wings or blades are arranged so as just to clip into the liquid, thereby causing a downward flow of liquid without preventing the formation of a vortex or eddy.

Acetylene generator. T. H. LEWIS. *Brit.*, 16,120, July 6, 1914. The container for the solid is provided with 1 or more apertures in the base, between which and the clamping member is placed absorbent material which serves to distribute the H_2O to the solid and also, in conjunction with the clamping member, to regulate the flow of the H_2O .

Kilns. W. RENNER and C. HOCKE. *Brit.*, 16,030, July 4, 1914. A discharging device for a shaft kiln comprizes a pair of oppositely rotating rollers preferably mounted on parallel shafts; these rollers serve to break up and discharge the clinker and also to set the lower contents of the kiln chamber in rotation in a horizontal plane.

Rotary furnace. W. ENGELHARDT. *Brit.*, 29,911, Dec. 29, 1913. The fuel is projected at a high velocity against some resistance in the furnace. Eddies are thus formed which result in a thorough mixing of the fuel and air. The resistance may take the form of projections from the furnace wall; or, it is stated, the slowly moving column of gases escaping from the furnace may act as the resistance. The fuel may be injected in a number of parallel or intersecting streams, preferably through slots in a plane inclined to the axis of the furnace.

Crucible furnaces. A. C. IONIDES. Brit., 15,778, July 1, 1914. In the operation of crucible and like furnaces heated by the combustion of a self-burning gaseous mixt. in a combustion chamber surrounded by a flue through which the combustion products pass downwards to an outlet below the level of the furnace, preheating one or both constituents of the mixt.

A pipet. P. SCHMIDT. Ger., 284,589, Feb. 19, 1914. Fig. 1 shows the app. in longitudinal section. Fig. 2 is a plan view, partly in section. The liquid to be measured is run into the container *a* through the branch tube *h* from the funnel top which is stoppered tightly with the stopper *i*. The liquid may be delivered through the tube *b*, connected with the container *a* and provided with the pear-shaped enlargement *c* which can be isolated from the container *a* by means of the stopcock *e*. The extension of tube *b*, beyond the chamber *c*, is enlarged to form the air chamber *g*, which encloses the end of the pipet *d* which passes through the stopper *m* (air-tight), to connect, by contact, with the

connect, by contact, with the tube *b*. The enlargement *g* communicates with the container *a* through a branch tube which passes through the cock *l*. When a definite amt. of liquid is to be withdrawn from the container *a* and measured, the cock *e* is opened while the cock *l*, in the

side tube, is in the closed position. The liquid in the container *a* is then subjected to air pressure, produced by compression of the bulb, and exerted through the section *k*. The liquid is thus forced into the enlargement *c*, charging it in such manner that when the app. is set up the air pressure forces the liquid has entered the pipet, as shown by the scale thereon, the cock *e* is closed and the cock *l* is opened, thereby cutting off the supply of liquid and forcing the measured column out through the pipet.

Device for delivering measured quantities of liquids. B. THURAU. Ger., 283,939, May 28, 1914.

Device for measuring vapor, gas, and liquid. J. H. REINEKE. Ger., 284,780, July 18, 1914.

Construction of discharge mechanism for multiple condensers and pumps for gas. AKT.-GES. DER MASCHINENFABRIKEN ESCHER, WYSS & CIE. Ger., 283,984, June 17, 1913.

Regulator for multiple step condensers for gas and air. ALLGEMEINE ELEKTRIZITÄTS-GES. Ger., 284,768, Sept. 12, 1914.

Regulating the feeding of ball mills. GEBR. PFEIFFER. Ger., 284,154, July 1, 1914. The charging device is automatically regulated by the flow of the ore, slag, etc., in such manner that as the flow increases the supply is cut down, and as the flow slackens the supply is increased.

Spraying device. H. RABE. Ger., 284,857, Sept. 16, 1913.

Crystallizing apparatus. E. KRÜGER GEB. KOWING. Ger., 284,696, Aug. 18, 1912. In a counter-current cooling app. a number of cooling tube systems are disposed in series with projections attached to the several tubes upon which the crystals form and grow while scrapers keep the tubes themselves clean.

Drying drums. MASCHINENFABRIK PETRY & HECKING, G. M. B. H. Ger., 283,954, May 25, 1913. Drums, through which the material is conducted, are arranged one within the other.

Cover for charging bells. H. STÄHLER. Ger., 284,668, Oct. 28, 1913. Constructional details of a cover for bells for cupola furnaces and the like.

Apparatus for separating water from flowing compressed air. R. POTH. Ger., 284,011, Dec. 23, 1913. The chamber traversed by the compressed air is completely filled with pieces of quartz, which remove the H_2O . The inclined bottoms of the chambers have openings to permit the passage of compressed air from chamber to chamber. The dry air leaves the app. through a vertical shaft.

Automatic lubrication of gas condensers. AKT.-GES. DER MASCHINENFABRIKEN ESCHER, WYSS & CIE. Ger., 283,959, June 13, 1913.

Sealing vacuum vessels. SIEMENS-SCHUCKERT-WERKE G. M. B. H. Ger., 284,047, June 14, 1914. The seal is especially designed for metal vessels and electrodes for metal vapor app. One or more sealing surfaces consist of metal deposited elec. on the parts to be sealed.

Roasting furnace. A. ZAVELBERG. Ger., 284,607, Feb. 5, 1913. The furnace is provided with mechanical raking devices, with the operating arms secured to a frame outside of the furnace.

A built-up stirring shaft for mechanical roasting furnaces. NICHOLS COPPER CO. Ger., 284,586, Mar. 10, 1914. Cf. C. A. 9, 782.

2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS.

Assistants: E. B. MILLARD AND A. B. CARTER.

Progress of microchemistry in 1913 and 1914. F. EMICH. *Chem. Ztg.* 39, 789-92, 838-40(1915).—A review with 159 references. J. H. MOORE.

Valence theory of J. Stark from a chemical standpoint. D. A. HAHN AND M. E. HOLMES. *J. Am. Chem. Soc.* 37, 2611-26(1915).—Abstract of "Die Valenzhypothese von J. Stark von Chemischen Standpunkt," by Paul Ruggli, Stuttgart, 1912 (cf. C. A. 7, 1439). E. B. MILLARD.

Conductivity and dissociation of some rather unusual salts in aqueous solution. CHAS. WATKINS AND H. C. JONES. *J. Am. Chem. Soc.* 37, 2626-36(1915); cf. C. A. 8, 3735; 9, 993.—The exptl. methods are described in *Publ. Carnegie Inst. Washington*, 230(1915). Tables are given of mol. conductivities expressed in Siemen's units, for 0, 15, 25 and 35°. The % dissociation has been calcd. from the relation $\alpha = 100\mu_9/\mu_0$, where μ_0 is the highest value of μ_9 measured. This "greatest diln." was $V = 4096$ in some cases and $V = 1024$ in others. For $Na_2S_2O_8$, e. g., the mol. cond. was greater at $V = 2048$ than at $V = 4096$, so 100% dissociation was assumed for the former vol. of soln. and no value was calcd. for $V = 4096$. The substances studied were $NaBrO_3$, $NaSCN$, $Na_2S_2O_8$, $Na_2S_2O_4$, Na_3PO_4 , $Na_4P_2O_7$, NaH_2PO_4 , Na_2WO_4 , $HCOONa$, Na_2CrO_4 , $Na_2Cr_2O_7$, $K_3Fe(CN)_6$, NH_4IO_3 , $NH_4H_2PO_4$, $(NH_4)_2CrO_4$, NH_4SCN , Li_2CrO_4 , and RbI . The conductivities for the chromates were in the order K , NH_4 , Na , Li , though NH_4 salts usually have higher conds. than K salts. Ions with the largest hydrating power generally have the largest temp. coeffs. of cond. At higher dilns. the temp. coeffs. of cond. for a given substance are greater than at lower dilns. E. B. M.

Construction of compound molecules with theoretical atoms, especially the systems of growth of the organic compounds of carbon and hydrogen. ALBERT C. CRRHORE.

Columbia Univ. *Phil. Mag.* 30, 613-23(1915).—An application of the inter-atomic force fields previously calcd. (*C. A.* 9, 2473). In the structure of a crystal the axes of revolution of the atoms are not parallel but take such positions that the turning moment of the force due to all the other atoms in the crystal on each atom is zero. But with the small number of atoms present in a simple mol. the equil. of turning moments demands that all the axes be parallel. That the edge of the elementary tetrahedron in the diamond is 2.5×10^{-8} cm. while the distance between the atoms in a compound mol. is near 10^{-10} cm., involves forces vastly greater, though of the same kind, in the latter case. Graphs are given showing the forces at all angles and a range of distances between two H atoms and between one C and one H atom. These are applied to mol. structures. The H_2 mol. is an isosceles triangle with one atom free to revolve about the line between the other two as an axis. CH_2 is stable as an isosceles triangle but readily takes up more H. CH_4 requires a tetrahedron with the C in the center and symmetrical with respect to the axis of the C atom, yet greater in height than in length or breadth. The H atoms are similarly located with respect to each other. C_2H_2 requires a lengthened hexagon with the two C atoms at the ends of the longest axis. The satd. rings are combinations of these hexagons; the hydrocarbon chains are rows of the CH_2 tetrahedrons. Benzene is a lengthened hexagon of C atoms with the H atoms near the shortest diam. In all these mols. each atom acts effectively on all the others; the function of the H is invariably to hold the mol. together and to counteract the repulsion between the C atoms.

G. L. WENDT.

Molecular weights of gases by an evaporation method. H. L. TRUMBULL. *J. Am. Chem. Soc.* 37, 2662-7(1915).—A 3-cc. flask of H_2O was connected with an atm. of dry air, H, or CO_2 in an Erlmeyer flask, and the rate of evapn. detd. from loss of wt. of the flask. The rate was assumed to depend only on the relative rates of diffusion of the atm. and H_2O vapor, if stirring effects were eliminated. The rates of evapn. were nearly proportional to the inverse squares of the densities of the gases. Theory requires the ratio 3.79 for H_2 /air; 3.39 was found. This different rate of evapn. into different gases is suggested as a means of detg. the mol. wt. of the gas.

E. B. MILLARD.

✓ Critical constants of normal butane, iso-butane and propylene and their vapor pressures between 0 and 120° . F. M. SEIBERT AND G. A. BURRELL. *J. Am. Chem. Soc.* 37, 2683-91(1915); cf. *C. A.* 9, 2583, 2614.—The gases were purified by fractional distn., sometimes under pressures as low as 1 mm. of Hg, until the vapor pressures were independent of the relative vols. of liquid and vapor. The plot of log. pressure against log. $1/T$ gave a straight line. The crit. phenomena were normal and different samples of the condensed liquid gave identical results. All the vapor in the exptl. tube could be condensed without a perceptible rise of pressure. The data are as follows:

Substance.	Temp. $0^\circ C.$	Press. mm. Hg.	Press. atms.	a.	b.
Normal butane.....	153.2	27113	35.67	0.02883	0.005470
Isobutane.....	133.7	27771	36.54	0.02562	0.005096
Propylene.....	92.6	34463	45.34	0.01668	0.003692

a and b are the corrections in the van der Waal equation.

E. B. MILLARD.

Vapor pressures of sulfur dioxide and nitrous acid at temperatures below their normal boiling points. G. A. BURRELL AND I. W. ROBERTSON. *J. Am. Chem. Soc.* 37, 2691-4(1915); cf. preceding abstr.—For SO_2 the vapor pressures range from 760 mm. at -11.0° to 0.5 mm. at -94.4° ; and for N_2O , from 760 mm. at -88.7° to 1 mm. at -144.1° . The data are shown in tables and curves.

E. B. MILLARD.

Equilibria in the systems of the higher alcohols, water and salts. G. B. FRANKFORTH AND STERLING TEMPLE. *J. Am. Chem. Soc.* 37, 2697-716(1915); cf. *C. A.* 7,

2176.—The PrOH (Kahlbaum's best) was further purified by treating with KF , CaO , CuSO_4 , Mg-Hg and finally Na-Hg ; it then $b_{760} 97.3-7.5^\circ$, has $d_{20} 0.8032$, $n_{20} 1.39023$, 1.37651 and 1.36786 for the H lines α , β and γ , resp. The purified iso- PrOH $b. 82.5^\circ$, has $d_{20} 0.7881$, $n_{20} 1.37960$, 1.36550 and 1.35584 for H , α , β and γ . Into a weighed Erlenmeyer flask, provided with a ground-glass stopper and a side tube carrying a thermometer, was introduced the salt, the flask weighed again, enough H_2O to just dissolve the salt added, the flask weighed, enough alc. added to cause a sepn. into 2 layers, a weighing again made, then H_2O added drop by drop until the mixt. became homogeneous and a final weighing made; successive points on the curve were then detd. by alternately adding enough alc. to produce a turbidity and H_2O to clear the soln. The readings were made at a temp. of $20^\circ \pm 0.2^\circ$. With KF and NaCl as the salts, spirit blue was used as the indicator; with K_2CO_3 and Na_2CO_3 , phenolph. The 7 systems containing, in addition to H_2O , PrOH and Na_2CO_3 , iso- PrOH and KF or K_2CO_3 , and allyl alc. and KF , K_2CO_3 , Na_2CO_3 or NaCl were studied. KF was found to be the most satisfactory dehydrating agent on account of the ease with which the end point can be detd. with widely varying compn. of solvent, and because it causes sepn. into 2 phases only, both liquid over a relatively large range in compn. of the solvent, and finally because of the large amt. of H_2O with which it combines to form its lowest hydrate. K_2CO_3 also works very satisfactorily. No evidence was found relating the salting out effect to the chem. constitution of the salts or alcs.; the salting out efficiency of a salt seems to depend rather on its solubility in the H_2O and the alc., on the amt. of H_2O with which it combines to form its lowest hydrate and on the ability of the alc. to replace the H_2O of hydration.

C. A. ROULLER.

Viscosities of solutions of cesium salts in mixed solvents. P. B. DAVIS AND H. C. JONES. *J. Am. Chem. Soc.* 37, 2636-42 (1915); cf. *Publ. Carnegie Inst.* No. 230 (1915).—The expts. are on the viscosities of solns. of CsCl and CsNO_3 in H_2O and binary mixts. contg. 25, 50 and 75% of MeOH , EtOH and Me_2CO with H_2O at 15, 25, and 35° , usually at 3 concns. of salt in each mixt. A 0.5 N soln. of CsCl in 75% Me_2CO could be prepd., but with a partial sepn. of the acetone from the solvent. On cooling below 10° a perfectly homogeneous mixt. was obtained which again sepd. into 2 layers on warming. The nitrate at this concn. merely remained partly undissolved. Both of the Cs salts lower the viscosity of H_2O and the 25% mixt. of all the solvents, and increase the viscosity of the 75% mixts. In 50% MeOH the chloride showed an increase in viscosity at all temps. for the most dil solns., and a tendency of the more concd. solns. to pass over into negative viscosity change, while the nitrate in the same solvent showed a decided negative viscosity effect. Expts. are in progress on the effect of these salts in glycerol and mixts. of it with H_2O .

E. B. MILLARD.

Electrical synthesis of colloids. H. T. BEANS AND H. E. EASTLACK. *J. Am. Chem. Soc.* 37, 2667-83 (1915).—The first part of this paper is a review, with bibliography, of the work on elec. formation of colloids, and the "complex" theory of their formation. Expts. were performed on the increase in elec. cond. accompanying the formation of a colloid in an arc of the metal under H_2O . This increase was 8 times greater for Pt than for Au , on account of a greater oxidation of the Pt , and the Pt sols were invariably more stable than the Au . Thus earlier evidence relating the stability of the sols and the presence of small amts. of certain electrolytes was confirmed. The sp. cond. due to the colloid proper is of an order 10^{-10} mhos, or 0.01% of that of conductivity H_2O . The presence of chloride, bromide, iodide, or OH^- ion in concns. from 0.0005 to 0.005 N has a marked stabilizing effect on Au sols, and furnishes a quick and reliable method of prepg. these sols. This effect is not produced by dispersion of the Au in pure H_2O and subsequent addition of the electrolyte. The particles in all these red sols have been shown by electrophoresis to be negatively charged. The

above stabilizing effect is not produced with fluoride, nitrate, sulfate or chlorate ion in similar concn., and seems to be related to the ability of the ion to form stable compds. with Au. No Au was ever obtained in the filtrate, however. Elec. synthesis of colloids is considered to consist of a thermo-mechanical dispersion of the metal, followed by the formation of a colloidal complex between the dispersed metal and certain ions present in the medium.

E. B. MILLARD.

The drop-weight method for determining surface tensions. ALLAN FERGUSON. Univ. Coll., North Wales, Bangor. *Phil. Mag.* 30, 632-7(1915).—A discussion of the influence of the "contact angle" on the wt. of a falling drop, based on the work of J. L. R. Morgan (*C. A.* 9, 1713). Since drop-weight and capillary rise measurements are proportional and the latter are always uncertain on account of the contact angle, the former may suffer also. If not, then at least the 30 results of M. which vary inexplicably are in error from this cause. F. recommends measurements by all methods on the same samples, especially of ether and of turpentine, which are known to have contact angles with glass of respectively 16° and 17° .

G. L. WENDT.

The action of certain colloids on ions during electrolysis. A. MUTSCHERL, M.D., German Hospital, New York. *Met. Chem. Eng.* 13, 353-7(1915).—The relative migration velocity of the ions of N $AgNO_3$ soln. was first detd. with the Hittorf app. A Ag anode and a Pt cathode were used, and concn. changes were measured after a 1-1.5 hr. run. The migration ratio was calcd. by Hittorf's method from the Ag deposited and the concn. change at the cathode. In the pure soln., the migration ratio for NO_3^- was found to be about 0.562. With the addition of 1% gelatin soln., the NO_3^- migration ratio decreased, the decrease being directly proportional to the amt. of added gelatin. The ratio finally became practically zero (0.053) with the addition of 2 cc. of 1% gelatin to 40 cc. of electrolyte, and further addition of gelatin caused the anions to assume a negative migration velocity; i. e., they migrated toward the cathode instead of toward the anode. Upon the addition of 5 cc. gelatin soln. to 40 cc. of the electrolyte, a migration ratio of -0.665 was attained. When the migration velocity was practically zero, a white, well-adhering Ag deposit was obtained at the cathode. In the presence of less gelatin than that required for this effect, the deposit was loose, brittle, and in the form of trees and striae, and the gelatin gathered around the anode in a slimy layer. When gelatin sufficient to cause negative anion migration was present, the deposit was gray or black, but firmly adherent. Such deposits when strongly heated changed color, indicating a loss of deposited organic matter. A second series of expts. was carried out in which the gelatin concn. remained const. at 2 cc. of 1% soln. per 40 cc. of electrolyte and the $AgNO_3$ concn. varied from 0.1 N to 0.3 N . With 0.1 N soln. the NO_3^- migration ratio was 0.240. Increasing $AgNO_3$ concn. was accompanied by decreasing NO_3^- migration ratio up to a concn. a little above 0.1 N , where the curve passed through zero as a minimum. Beyond this point, increase in $AgNO_3$ concn. caused an increase in NO_3^- migration ratio, which reached 0.328 for 3 N soln. With concns. below N , the Ag deposit was gray or black and contained gelatin. With N soln. a pure deposit was obtained, while with concns. above N , the deposit, although pure, was striated and badly adherent. Expts. with N $CuSO_4$ were next carried out in an H-shaped tube with one electrode in each leg. The concn. changes in the soln. around each electrode were examd., and the deposited Cu weighed. As in the previous expts., any gelatin present in the cathode deposit was weighed and expressed as metal, thus causing a slight error when the gelatin concn. was high. The curve obtained by plotting migration ratio against gelatin concn. for $1/2$ SO_4^{--} was a straight line as in the case of NO_3^- . The migration ratio decreased steadily from 0.650 for the pure soln. to -0.896 for a soln. containing the equiv. of 200 cc. of 1% gelatin soln. per 40 cc. of electrolyte. (In order to avoid excessive diln., an equiv.

amt. of concd. soln. was used instead of 1% gelatin where the amt. to be added was great.) The amt. of gelatin required to affect the migration of $\frac{1}{2}\text{SO}_4^{--}$ was 45 times as great as the amt. required to produce an equal effect upon NO_3^- . This indicates that the effect of gelatin upon electrolytes is due to selective adsorption, since Freundlich (C. A. 4, 2764) has shown that the pptg. power of univalent ions upon colloidal $\text{Fe}(\text{OH})_3$ is to the pptg. power of bivalent ions as 1 to 40 or 50. The migration ratios of $\frac{1}{2}\text{Cu}^{++}$ also gave a straight-line curve, increasing from 0.380 with the pure soln. to 2.042 with a soln. containing the equiv. of 200 cc. of 1% gelatin per 40 cc. of electrolyte. The curves for $\text{SO}_4^{--}/2$ and $\text{Cu}^{++}/2$ are parallel lines when plotted with migration toward the cathode as +, and toward the anode as -. This is to be expected, since it can be shown mathematically that whatever velocity is lost by one ion must be gained by the other in order that the total current may be carried. Evidently at the deposition optimum the charge of the anions is exactly neutralized by the colloid. The "isocolloid" formed does not migrate, and accumulates in the electrolyte. At the anode in this case, the Ag^+ ion, instead of combining with NO_3^- , releases H^+ ions from the HNO_3 present. The H^+ in turn reacts with the gelatin- NO_3 complex to form HNO_3 and releases the + charged gelatin which is again available to combine with more NO_3^- . But since the isocolloid complex does not migrate, it must be brought close to the anode by stirring. Theoretically, there should be no loss of gelatin or acid, but actually the gelatin does break down slowly. The expenditure of gelatin is considerably greater when the anion charge is overbalanced by an excess of gelatin, causing the complex to migrate to the cathode and be deposited there. Conversely, if insufficient gelatin is added, it migrates to the anode and separates out as a slimy layer. The neutralizing effect of gum arabic and starch upon anions was investigated (no data given); and the relative values of gelatin, gum arabic and starch were found to be inversely proportional to the "Goldzahl" or "gold numbers," viz., 200, 5, and 0.04, resp., assigned to these colloids by Zsigmondy on the basis of their protective action upon colloidal gold.

F. A. STRAUSS.

The relative migration velocities of the ions in complex electrolytes. A. MURSCHELLER. *Met. Chem. Eng.* 13, 439-42 (1915); cf. preceding abstr.—The migration velocities of the ions in a few common plating solns. containing double salts were detd. A $\text{KAg}(\text{CN})_2$ soln. was first examd. The anion here is $\text{Ag}(\text{CN})_2^-$, which, when a Ag anode is used, gives up its charge there and forms $\text{AgAg}(\text{CN})_2$. The cation is K^+ . Ag is not deposited directly at the cathode, but only after the secondary reaction, $2\text{K} + 2\text{KAg}(\text{CN})_2 = 4\text{KCN} + 2\text{Ag}$. The K^+ merely frees Ag^+ ions which require new electrical energy for their deposition; hence the equiv. of the Ag^+ ions which originate at the anode are not deposited at the cathode, and an increase in Ag concn. is to be expected around the cathode. This conclusion was verified exptly. by electrolyzing a $\text{KAg}(\text{CN})_2$ soln. containing a slight excess of KCN in an H-tube with Pt cathode and Ag anode, and detg. the increase in the Ag concn. in the cathode compartment. Solns. containing metal- NH_3 double salts, viz., the solns. commonly used for Zn and Ni plating were next examd. Here the metallic ion and the NH_4^+ ion migrate together to the cathode, where the NH_4^+ after being liberated breaks down giving NH_3 , which forms complex ions of the type $\text{Ni}(\text{NH}_3)_4^{++}$ with the metal present. This complex ion forms an intermediate product which dissociates in turn, forming with the anions a salt by means of which the anions are withdrawn from the function of transporting the current. Hence the cations alone must transport the current, and the full equiv. of the metal deposited must migrate toward the cathode. If the ratio between metal and NH_3 salt is correct, there should be no decrease in the metal ion concn. at the cathode during the run. This theory was investigated by electrolyzing Zn and Ni plating solns. in the app. already described. The Ni soln. contained 46 g. $\text{Ni}(\text{NH}_4)_2(\text{SO}_4)_2$ per l. and 5

drops H_2SO_4 . The Zn soln. contained ZnSO_4 50, $(\text{NH}_4)_2\text{SO}_4$ 10, ZnCl_2 2.5, and H_2O 250 g. On electrolysis, in each case the total metal concn. in the cathode compartment was found to decrease by about 10% of the weight of the metal deposited. This may be explained by the fact that while the initial NH_4 required for the formation of complex ions is being formed by the discharge of NH_4^+ ions, the anions are carrying a part of the current, and the cation velocity is correspondingly decreased. M. concludes that smooth deposits from solutions of metallic salts are formed only when the cations migrate toward the cathode as fast as they are deposited, thus keeping the cation concn. at the cathode const. This condition can be realized by the addition of the proper amt. of a + charged colloid, or by the use of electrolytes containing suitable complex ions.

F. A. STRAUSS.

Electrical transference in amalgams. G. N. LEWIS, E. Q. ADAMS AND EDITH H. LANMAN. *J. Am. Chem. Soc.* 37, 2656-62(1915).—A A-shaped tube carries heavy Pt wires fused in the ends of the branches, and an arrangement for filling with amalgam after the tube had been heated and exhausted to 0.0001 mm. Hg. The tube is 2 mm. in internal diam., and 20 cm. long. A current of 4 to 8 amps. was passed through the app. for several days, so as to give approx. 1000 amp.-hours. The current was read with an ammeter. Fluctuations were negligible in comparison with other exptl. errors. At the conclusion of the expt. the amalgam (generally contg. 0.3 to 0.4 milli-equivs. of dissolved metal) was withdrawn and analyzed by titration with 0.01 N HCl, and detn. of the excess acid with NaOH, using rosolic acid as an indicator. The titrations were performed in the absence of CO_2 . The number of equivs. carried per faraday is 2.9×10^{-8} in Na amalgam of 3.24 atomic %, and 0.29×10^{-8} in Na amalgam of 0.577 atomic %. In K amalgam of 2.16 at. % it is 3.6×10^{-8} . To explain this motion of Na it may be assumed that a dil. amalgam is composed of small regions whose centers are Na atoms, embedded in a mass which has all the properties of Hg. Then an electron, on meeting one of these regions, will be retarded, and the region will be impelled in the direction of the negative current. Expts. are now in progress on the e. m. f. of concn. cells consisting only of metals, as a possibly more exact means of detg. transference numbers of amalgams.

E. B. MILLARD.

Flow of air and steam through orifices. A. L. WHITCOTT. *Power* 42, 515-6(1915).—Results of exptl. detns. of coeffs. applicable to Fleigner's formula and to the theoretical formula for the flow of a fluid through an orifice.

C. G. F.

The kinetic theory of gases. II. SAUL DUSHMAN. *Gen. Elec. Rev.* 18, 1042-9 (1915).—D. considers the deductions from the theory of molecular collisions. Tables of values are given of the av. free path and mol. diameter for some of the more common gases.

C. G. F.

The electron theory of metallic conduction. V. G. H. LIVENS. Univ. Sheffield. *Phil. Mag.* 30, 549-59(1915); cf. C. A. 9, 881, 1576, 2733.—An amplification of the theories of Lorentz, Drude, Thomson, Jeans, Wilson and Bohr, considering mainly the effect of collisions on the velocity of the electrons. The Lorentz analysis is considered the more fundamental.

G. L. WENDT.

The electron theory of the Hall effect and allied phenomena. G. H. LIVENS. Univ. Sheffield. *Phil. Mag.* 30, 526-48(1915).—A detailed mathematical restatement of the theory of Drude (*Ann. Physik* 1, 566; 3, 369) and of J. J. Thomson. It is suggested that the effective magnetic field for the phenomena is not a continuation of the external field but is augmented by the addition of a purely local field within the metal due to the polarization in the immediately surrounding molecules. In the ferromagnetic metals this effect preponderates.

G. L. WENDT.

Cases of ionization of the atmosphere. J. A. FLEMING. *Electrician* 75, 348-50 (1915).—A discussion of the manner in which a permanently charged layer in the upper atm. may be formed by the arrival and presence of light impelled particles from the sun. The existence of such a layer is shown to be possible, but is not proved.

A. B. GLADDING.

Controlling infra-red emission. W. W. COBLENTZ. *Elec. World* 66, 1155-6 (1915); cf. U. S. Pat. 1,135,663(1915).—A preliminary paper. C. briefly describes his new glower. The light-producing part of the glower consists of a thin thread of a complex Al silicate, such as feldspar, which is attached to a thin rod of Al_2O_3 for a support. The luminous efficiency of this glower is considerably greater than that of the Nernst glower since the radiation of energy in the infra-red is decidedly less (curves are shown). The glower emits a banded spectrum similar to that of a gas. Cf. C. A. 3, 614; 4, 1262.

C. G. F.

The critical field at a discharging point. A. M. TYNDALL. *Phil. Mag.* 30, 637-44 (1915).—Measurements of the mechanical force on hemispherical points of varying radius on bifilar suspensions during an elec. discharge confirm Townsend's deduction from the theory of ionization by collision that the product of the critical field and the radius of the point is const. when the pressure of the gas is so varied that its product with the radius is also const. An additional supply of ions from a smaller discharging point reduced the critical field by a large fraction.

G. L. WENDT.

Mutual electromagnetic mass. J. W. NICHOLSON. *Phil. Mag.* 30, 659(1915).—A discussion of priority.

G. L. WENDT.

The calculation of series in spectra. W. M. HICKS. Univ. Sheffield. *Phil. Mag.* 30, 734-7(1915).—A suggestion on the procedure.

G. L. WENDT.

The calculation of series in spectra. H. G. SAVIDGE AND J. W. NICHOLSON. *Phil. Mag.* 30, 563-8(1915).—Reference tables are presented from which the wave number of a third line in a suspected series may be found from the difference in wave number of two successive lines. They are calculated from Rydberg's formula but are equally applicable to Fowler's enhanced line series.

G. L. WENDT.

A relation between natural and magnetic rotatory dispersion. JOSEPH DAHLEN. Univ. Münster. *Z. wiss. Phot.* 14, 315-42(1915).—Wiedemann (1851) formulated a much quoted law to the effect that the ratio of the natural optical rotation and the magnetic rotation of various substances, R_n/R_m , did not depend upon the wave length of the light used. This law of late has been so qualified by exceptions that its validity for any case is questionable. In the present work the law was tested for crystals of right and left handed quartz, $NaClO_3$, $NaBrO_3$, $Sb_2S_3 \cdot Na_2S + 9H_2O$, $SrS_2O_6 + 4H_2O$, $C_{12}H_{10}O_{11}$, and several organic liquids. The law was not found valid for optically isotropic crystals, or for the org. liquids tested. The law may hold for uniaxial crystals, but the exptl. proof is not sufficient to establish this fact definitely.

PAUL D. FOOTE.

The dispersion of carbon dioxide in the infra-red region of the spectrum. C. STARESCU. Tübingen. *Phil. Mag.* 30, 737-43(1915); cf. C. A. 9, 3022.—A search through the region $\lambda = 0.8\mu$ to $\lambda = 13\mu$ shows a marked absorption band at $\lambda = 4.270\mu$ and the tendency toward another band at $\lambda = 14.7\mu$. The formula for the dispersion of CO_2 is still to be found.

G. L. WENDT.

The ultra-violet spectrum of elementary silicon. J. C. McLENNAN AND EVAN EDWARDS. Univ. Toronto. *Phil. Mag.* 30, 482-4(1915).—Beyond the spectrum measured by Crookes (C. A. 8, 3394) are 17 lines, lying between 2124.4 and 1842.2 Å. They were measured by means of a fluorite spectrograph and compared with Zn and Al spectra.

G. L. WENDT.

The absorption spectra of mercury, cadmium, and zinc vapors. J. C. McLENNAN AND EVAN EDWARDS. Univ. Toronto. *Phil. Mag.* 30, 695-700(1915).—Absorption bands were measured as follows: For Hg: $\lambda = 1849.6 \text{ \AA. U.}$, strong, symmetrical; 2338, diffuse, complex; 2536.72, asymmetrical. For Cd: 2288, strong, symmetrical; 3260.17, narrow, sharply defined. For Zn: 2139.3, strong, symmetrical; 3075.99, very narrow, sharply defined. With the exception of the band λ_{2338} , each of these is the first member of a series. G. L. WENDT.

The infra-red emission spectrum of the mercury arc. J. C. McLENNAN AND RAYMOND C. DEARLE. Univ. Toronto. *Phil. Mag.* 30, 683-95(1915).—Thirteen lines in the Hg arc spectrum are recorded lying between $\lambda = 1.00\mu$ and 3.02 , including the disputed lines at 1.04 and 3.02 , as well as three new lines: 1.067 , 1.090 and 1.270μ . Their series relationships are discussed. G. L. WENDT.

A further study of the fluorescence produced by ultra-Schumann rays. C. F. MEYER AND R. W. WOOD. *Phil. Mag.* 30, 449-59(1915); cf. *C. A.* 5, 1019; 8, 2521.—The passage of a spark between a Cu point and a Cu plate is accompanied by a radiation which excites fluorescence in the surrounding atmosphere. Through a slit in the plate a "jet" of the rays was admitted to a dark chamber and the spectrum of the fluorescence was photographed by a quartz spectrograph. The water band was always present when the gases contained moisture but could be interrupted when a thin stream of dry air or N was blown across the jet. The N_2 lines (3369, 3556, and 3778) are strong in pure N but are extinguished if O is present. I vapor gives visible as well as ultraviolet fluorescence. Fluorite and cryst. quartz are only slightly transparent to the exciting radiation, which shows the latter to be in the ultra-Schumann region. The rays which excite the water band pass more readily through fluorite than do those exciting the N lines; the reverse obtains with quartz. Fused quartz and mica are opaque. The index of refraction of the rays in quartz is 1.75 ± 0.08 . The rays which excite the water band were reflected from a deposit of Si on glass. G. L. WENDT.

Light absorption and fluorescence. III. E. C. C. BALY. Univ. Liverpool. *Phil. Mag.* 30, 510-26(1915); cf. *C. A.* 8, 3749; 9, 1001.—In part II it was shown that if ν be the characteristic vibration frequency in the ultraviolet or visible bands, pairs of absorption lines are found whose frequencies are equal to $\nu + \nu_s$, where ν_s stands for the frequencies of the short-wave infra-red bands. If Bjerrum's relationship (cf. *C. A.* 8, 859) holds throughout the spectrum the values of ν_s must represent certain values of $hn/2\pi^2I$, where I is the moment of inertia, h Planck's constant, and n a series of whole numbers, 1, 2, 3, etc. The abnormal intensity of certain bands in the infra-red spectra is attributed to the convergence frequency of two or more such series in which I has different values. On this principle the "basis constants" of H_2O , NH_3 , C_2H_4 , and aliphatic hydrocarbons were calcd. Using the 4 basis constants for C_2H_4 , the frequencies of about 90 lines in the ultra-violet absorption band of C_2H_4 are calcd. and agree closely with the measurements of Grebe and of Hartley. The infra-red spectrum of a compd. is shown to be an additive function of the spectra of its constituent radicals, certainly in the case of phenol, aniline, myrcyl alc., and triethylamine. The wave-lengths of the lines in the ultraviolet absorption bands of phenol and of aniline were calcd. from the basis consts of C_2H_4 and H_2O and of C_2H_4 and NH_3 with excellent agreement with observed values. G. L. WENDT.

The use of phosphorescing calcium sulfide in the bacchanalian rite. W. P. JORISSEN AND J. H. WIETEN. *Chem. Weekblad* 12, 768-73(1915).—A chem. and historical hypothesis, in which the authors try to explain the mysteries of Bacchus, as described by Livius and Pausanias. The use of phosphorescing CaS is supposed to account for the unextinguishability of the torches carried by the bacchantes.

J. T. FLOHLL.

Ionic mobilities in hydrogen and nitrogen (HAINES) 3. Ionization of hydrogen by X-rays (SHEARER) 3.

3. RADIOACTIVITY.

WILLIAM H. ROSS.

The mobilities of ions in air at high pressures. J. C. McLENNAN AND DAVID A. KEYS. Univ. Toronto. *Phil. Mag.* 30, 484-91(1915); cf. *C. A.* 6, 1400, 2205.—The ionic mobilities calcd. by Rutherford's formula from the current between two plate electrodes, one of which was covered with Po, showed that for pressures not much above 67 atms. the mobility varies inversely as the pressure, but for higher pressures (up to 181.5 atms.) the mobility decreases less rapidly. The mobilities of the positive and negative ions approach each other at higher pressures. It is surmized that in liquid air they are equal. G. L. WENDT.

The delta radiation emitted by zinc when bombarded by alpha rays. J. C. McLENNAN AND C. G. FOUND. Univ. Toronto. *Phil. Mag.* 30, 491-502(1915).—A freshly scraped plate of Zn exposed to bombardment by α -rays from Po in a high vacuum emits 3 slowly moving electrons for each α -ray impact. The electron emission decreases if the plate remains in the vacuum. A fresh surface deposited from Zn vapor in a high vacuum emits no electrons at first but the emission grows with the absorption of air by the Zn. Cf. Küstner, *C. A.* 8, 1382. G. L. WENDT.

Ionic mobilities in hydrogen and nitrogen. W. B. HAINES. *Phil. Mag.* 30, 503-9 (1915).—The persistence of negative ions with mobilities of 367 cm./sec. per v./cm. in N at atmospheric pressure was proved, but these electrons are very sensitive to some impurities. Traces of I, Cl, SO₂, N₂O, CS₂ and CHCl₃ remove them completely; 0.05% of O removes half; 2% of CO₂ removes only a third. The effect of H is very small, and in pure H electrons with mobilities of 170 cm./sec. exist in the free state. The higher the mobility of the ion, the greater its sensitiveness to impurities. G. L. WENDT.

The relation between the life of radioactive substances and the range of the rays emitted. F. A. LINDEMANN. Farnborough. *Phil. Mag.* 30, 560-3(1915).—Both the disintegration law, $X = X_0 e^{-\lambda t}$, and the rule of Geiger and Nutall, $\log \lambda = A + B \log R$, can be deduced mathematically from 2 assumptions: (1) the nucleus of a radioactive element, supposed to contain particles in movement, becomes unstable when N independent particles all pass through some unknown critical position within the short time τ ; and (2) the time τ is of the order of the time taken by a strain to traverse the nucleus. If each particle passes through the critical position ν times per sec., the disintegration const. λ can be shown to equal $(\tau \nu)^N$. The const. $B = \frac{1}{N} \log N$, and N is therefore 80 and a const. for all the radioelements. The const. λ takes the form R^{80} , whence the explosion of an atom requires the fortuitous coincidence of some 80 independent events. G. L. WENDT.

The decrease of velocity of swiftly moving electrified particles in passing through matter. N. BOHR. Univ. Manchester. *Phil. Mag.* 30, 581-612(1915).—The distribution of velocities in a beam of α - or β -rays on passage through matter is developed on the basis used in a former paper (*C. A.* 7, 936). Using Rutherford's nucleus atom, the loss of kinetic energy of a penetrating particle depends on the number of electrons in the atom and the frequency of their characteristic vibration. In the case of α -rays the probable variation from the mean rate of velocity decrease is small, less than 1% varying more than 5% from the mean. For β -rays there is a sharp max. in the rate of decrease at a unit electron concn. The thus calcd. ranges of α -rays in H and He agree

closely with the observed. When the at. number of air is taken as 14.4 the velocity curve is very near that observed by Marsden and Taylor (*C. A.* 7, 3270) so that the velocity curve is an independent means of detg. the at. number. That Marsden and Taylor could observe no α -particle after its velocity had been reduced to 0.42 of the original is attributed to a lack of homogeneity in the beam. For absorption in Al and the heavier elements the calcns. by this theory are only approximate. The theory for β -rays agrees with the data of Varder (*C. A.* 9, 1875), which seems to vindicate both the premise that the electromagnetic mass increases with the velocity and the principle of relativity that the longitudinal mass is not equal to the transversal mass, since both are used effectively in the calcns. It is further shown that recent measurements on the ionization produced by α - and β -rays agree well with Thomson's theory of the mechanism (*C. A.* 6, 1873), provided allowance is made for secondary ionization by the electrons ejected from the atoms in the primary ionization. G. L. WENDT.

The decrease in velocity of beta particles in passing through matter. W. F. RAWLINSON. Univ. Manchester. *Phil. Mag.* 30, 627-32(1915).—A measurement of the radius of curvature of a narrow beam of β -rays under a const. magnetic field and of the decrease in the radius with the interposition of thin absorbing screens. According to Bohr's theory the decrease in velocity is inversely proportional to the cube of the velocity of the β -ray and is less the higher the at. wt. of the absorber. These relations were verified, but only roughly on account of the diffuseness of the beam after absorption. The velocity decrease is less in Sn than in mica. G. L. WENDT.

The ionization of hydrogen by X-rays. GEORGE SHEARER. Univ. Edinburgh. *Phil. Mag.* 30, 644-58(1915).—The ionization of H by the characteristic X-rays from Cu was found to be 0.0018 of the ionization in air, but when X-rays from Sn, which have a greater frequency, were used the value rose to 0.0035. This may be due to a characteristic radiation of H of such a wave-length that it can be excited only by rays of a frequency of the Sn rays or greater, but it is more probably due to AsH_3 or other impurities which radiate under the influence of the rays of higher frequency. When the less pure H from Zn and H_2SO_4 was used in place of electrolytic H the ionization increased markedly. The existence of such a high frequency radiation in H is improbable on the basis of Bohr's calcn. of the H spectrum, which predicts that the highest frequency possible is 3.26×10^{15} , in the extreme ultraviolet, and the same figure is obtained from extrapolation of the values for the K series spectra of the elements, as well as from the ionizing potential in H. The fact that H is practically incapable of ionization by X-rays is attributed to the wide difference between the wave-length of the exciting radiation and its known characteristic radiation. Their ratio is 2000 for Sn rays in H but only 50 in air. G. L. WENDT.

A comparison of radium standard solutions. J. MORAN. *Phil. Mag.* 30, 660-4 (1915).—The weak Rutherford-Boltwood standard soln. at McGill Univ., with 1.57×10^{-9} g. Ra per cc. was found 2% lower than the Washington standard; the strong standard soln., 100 times as strong, is 4% lower than the Washington standard. The measurements were made by the Em method, the Em being driven from the soln. by boiling and measured in a gold-leaf electroscope. On successive boilings the solns. lose their emanating power and give results 10% too low, but the full value is restored by the addition of HCl soln. (19%). No explanation of this is offered. G. L. W.

The production of wave-movements by impulses with special reference to the space-lattice effects with Röntgen rays. L. ZEHNDER. Berlin. *Verh. deut. physik. Ges.* 17, 336-42(1915).—If only the principal angle of reflection from a three-dimensional lattice system is considered, $2d \cos \alpha$, where d is the spacing of the lattice and α is the angle of incidence of the wave on the plane of the lattice, gives only the distance between the units of the lattice which are concerned in the reflection, and this

may be a multiple of the wave-length reflected and not the true wave-length as is assumed in X-ray measurements. The true length can be obtained only by observing the reflection at other angles, where the lattice, acting as a diffraction grating, throws a spectrum which will contain an intense line at the true wave-length. G. L. W.

The phenomena occurring on the illumination of edges with Röntgen rays. J. LAUB. Buenos Ayres. *Verh. deut. physik. Ges.* 17, 354-6(1915); cf. *C. A.* 8, 3529, 3754; 9, 174, 552.—X-rays passed through a narrow slit are partially refracted and on striking a photographic plate show lines and bands surrounding the central line. Passage through a narrow circular diaphragm forms a series of concentric rings. The material forming the edge has no influence on the phenomena, but these depend on the hardness of the X-rays and the material of the anti-cathode. When the X-rays are focused on the edge, the lines on the plate form a close two-dimensional rectangular lattice. With a strong source of rays the refracted lines can be seen on a phosphorescent screen. The lines are entirely unlike those due to scattering when rays have passed through thin plates. If the ray is passed through a thin Pt foil after traversing the slit, the refracted lines disappear though the central image is bright. Heating a slit sheet of steel to redness has no effect on the refraction. G. L. WENDT.

The adsorption and precipitation of the radioelements. FRITZ PANETH. Radium Inst., Vienna. *Sitzb. kais. Akad. Wiss., Wien, Abt. IIa* 123, 2349-61(1914); cf. *C. A.* 9, 553, 1875.—The radioelements are readily pptd. by adsorption on ppts. with whose anion the radioelement forms an insol. compd., even though the concn. is far below the solubility limit for the radioelement. In the case of isotopes, as Th B adsorbed on PbSO_4 , this is explained by the kinetic exchange of PbSO_4 mols. between the soln. and the solid phase. Among the mols. entering the solid phase during the equil. are some of $(\text{Th B})\text{SO}_4$, which impoverishes the soln. with respect to the radioelement although the total concn. of the isotopes in soln. is unchanged. The efficiency of the adsorption depends on the relation between the number of mols. of the adsorbent in the surface layer and in the soln. and is therefore greater the more insol. is the adsorbent. For the low concns. of the short-lived elements the amt. adsorbed should be proportional to the concn. To explain the efficient adsorption by similar though not isotopic ppts., such as Th B by BaSO_4 , P. assumes that even in the solid state the ions are dissociated and separate and the valence bonds extend not only to the consort ion but to all in the vicinity and are essential to the cohesion of the solid state. This view is based on the evidence from W. L. Bragg's X-ray spectrometer (*C. A.* 8, 1236) that in the NaCl crystal Na and Cl are separate. An insol. salt is therefore one whose ions have a greater attraction for each other than for H_2O and so tend to coagulate in the solid state. $(\text{Th B})\text{SO}_4$ is insol. and so a Th B ion will be held by the SO_4 ions in the solid Ba-SO_4 ionic mass nearly as firmly as a Ba ion is. The efficiency of the adsorption depends then on the solubility of the $(\text{Th B})\text{SO}_4$ only as it affects this adsorptive attraction and without direct regard to the solubility product. No chem. similarity between the radioelement and the cation of the adsorbing ppt. is necessary beyond the mutual attraction for the anion. G. L. WENDT.

4. ELECTROCHEMISTRY.

COLIN G. FINK.

Contributions of the chemist to the electrochemical industry. W. S. LANDIS. *J. Ind. Eng. Chem.* 7, 944-5(1915).—A part of the symposium at the Seattle meeting of the Am. Chem. Soc. E. H.

Electric furnace power loads. F. T. SNYDER. N. E. L. A. convention, June, 1915, San Francisco. *Elec. World* 65, 1527(1915).—At present about 1,000,000 h. p. is

used in elec. furnaces, principally in the manuf. of Al, CaC_2 , steel and N products. The central station power load from these industries may be developed greatly, if low rates are given. They furnish a very desirable load because they can be shut down for several hrs. at the time of peak load. The cost of repairs and replacements depends greatly upon the number of electrodes. This will favor the development of a one-electrode furnace for single-phase power.

A. B. GLADDING.

Electric furnaces in Italy. ANON. *Elec. Rev. West. Elec.* 66, 1159(1915); *Z. Elektrochem.* 21, 295-6(1915).—Statistics of elec. furnaces and elec. furnace products in Italy during 1913.

A. B. GLADDING.

Commercial application of resistance furnaces. C. W. BARTLETT. N. E. L. A. convention, June, 1915, San Francisco; through *Elec. World* 65, 1526-7(1915).—A general review of the applications of elec. furnaces. A number of special furnaces are described in the original.

A. B. GLADDING.

The electric furnace in the foundry. J. H. GRAY. *Iron Age* 96, 798-800(1915).—G. distinguishes between the arc and induction types and then discusses the arc furnace. Acid furnaces should be lined throughout with SiO_2 , while basic bottoms consist of magnesite brick covered with layers of sintered grain magnesite. A mixt. with 10-20% of open-hearth slag admits of better sintering and fritting. This mixt. is added in layers and each layer is heated white by the arc before the succeeding one is applied. Dolomite repairs corrosion above the slag-line. Roofs are always made of SiO_2 . The walls may be made of SiO_2 , magnesite-, or Cr-brick and should be 13-18 in. thick. The roof should be 9 in. thick. The electrodes consist of graphite or amorphous C in sections of convenient length and joined by nipple or screw thread. Graphite has a higher cond., less breakage and is more easily handled, but costs more; it is a better conductor of heat and electricity, minimizing its advantages. The consumption in kw. per ton steel is greater where the heat radiates from the arc upward and downward. The number of electrodes depends upon the kind of current and whether or not elec. connections through the bottom are used. With bottom connections single phase requires 1 electrode, 2-phase 2, 3-phase 3, while without bottom connection single phase requires 2, 2-phase 4 and 3-phase 3. The 3-phase system is most prevalent in America. Grouping of electrodes and a table of sizes are given. The electrode holder should form good elec. connection with the electrode, be easily tightened and loosened and water-cooled to prevent arcing. A water-cooled collar or other cooler causes fumes to condense on it and form smut which seals the opening between electrode and collar, making the furnace more nearly air-tight. *Ibid* 878-81.—Linings, roof, electrodes, elec. connections and mechanism of the furnace suitable for foundry use are described. Fundamental consideration of all parts of their operation is given. Tables show the size of Cu conductors and electrodes for furnaces of different capacities.

W. H. BOYNTON.

Details of Stassano furnace at Warman Steel Casting Co., Redondo, Cal. W. M. MCKNIGHT. N. E. L. A. convention, June, 1915, San Francisco. *Elec. Rev. West. Elec.* 67, 13(1915); see *C. A.* 8, 465.

A. B. GLADDING.

New installations of Héroult furnaces. ANON. *Iron Age* 96, 937(1915); cf. *C. A.* 2, 2487.—New 6-ton furnaces are in course of erection at Lockport, N. Y., Baltimore, and Wellend (Ont.). These bring the total up to 30 H. furnaces in the U. S. and Canada.

C. G. F.

Steel electrically produced directly from ore. ANON. *Elec. Rev. West. Elec.* 67, 904(1915).—An elec. smelter at Belleville, Canada, utilizes the heat from waste gases by preheating the charge which is passed through two wrought-iron pipes 8 ft. long and increasing from 14 to 18 in. in diameter. These are enclosed in the preheater stack

which is provided with baffles to facilitate circulation. The charcoal, limestone and ore are all crushed to pass a 1 in. mesh. Two-phase current, connected by the Scott connection, is introduced through 3 in. electrodes threaded to feed continuously. The plant has been in operation for about 2 months and has produced sound ingots of high-C steel for ore containing 7.5% Ti. A 3-ton furnace is soon to be erected.

W. E. RUDER.

The fixation of atmospheric nitrogen. Discussion. J. W. RICHARDS, *et al. Proc. Am. Inst. Elec. Eng.* 34, 2656(1915).—R. points out that of the total of 250,000 h. p. available at Rjukanfos, Norway, only 3500 h. p. or 1.4% is actually utilized. The cyanamide process reaches 6%. The Serpek process produces Al_2O_3 as a by-product. The efficient conversion of NH_3 to HNO_3 is an important consideration. J. L. R. HAYDEN reports that his expts. with arcs of different temps. seemed to show no direct relation of the NO concn. to the arc temp. as depending upon the arc stream material. He concludes that the NO production by the elec. arc is essentially a dissociation phenomenon. A table of arc stream materials arranges itself, with the exception of Cu, in their efficiency of NO production approx. inversely to their b. ps. D. B. RUSHMORE said that the effect of the elec. field has been given little consideration and might be of extreme importance. F. B. WASHBURN shows that a great mfg. industry should be located where deep water can be reached rapidly on the Atlantic or Pacific coast. The tonnage ratio of raw material to finished product would be about 4 to 1. L. L. SUMMERS dwells upon the elec. effect of the arcing system with its ionizing element. The reason why a large arcing system is not more effective is that at the temps. involved, dissociation is so active that, even though the elec. effect is sufficient, the product cannot be removed rapidly enough.

W. E. RUDER.

Electrical precipitation. Discussion. S. DUSHMAN, *et al. Trans. Am. Inst. Elec. Eng.* 34, 2646-52(1915).—D. describes a simple device for rectifying currents at high potential called the "kenotron" (cf. C. A. 9, 1008). This device is particularly adapted to elec. pptn. W. W. STRONG does not believe that the influence machine has any future in this work. Referring to the application of elec. pptn. to steam locomotives, the chief difficulty is that the source of power is usually d. c. It is also impossible to treat gases flowing at a high speed. It is being applied, however, when fires are being started. Pptn. by means of polarization is impracticable because a max. corona current between the electrodes is necessary. The insertion of inductance in the high tension d. c. circuit has been found at times to be an advantage. There is a preferred design of precipitator for any given gas problem. Expts. have shown a 4 ft. pipe to be feasible and practicable and 200,000-250,000 v. have been used satisfactorily. It is also possible to have too great a potential for the most economical operation. H. P. HILL describes tests on rectifying device and decided that a positive contact switch commutating the entire wave was the most practical and efficient device.

W. E. RUDER.

The uses of colloids in plating solutions. E. S. THOMPSON. *Brass World* 11, 251-2(1915).—Deposition of Pb and Sn in cryst. form from caustic baths is prevented by addition of gelatin, glue, etc. The colloid acts as a filter preventing cryst. substances from passing through it to reach the cathode. The metal in soln. is deposited as a secondary reaction. Glue takes up O at the anode and carries it to the cathode.

W. H. BOYNTON.

Alternating current service from battery. J. A. WALTON. *Elec. World* 66, 975-6 (1915).—A storage battery has been installed in a sub-station to carry the a. c. load whenever the normal supply is interrupted. The battery is floated on d. c. busbars, normally energized by motor-generator sets, and providing control equipment which will in emergencies allow the battery to feed back into these sets, hence maintaining

a. c. service in the distribution system connected to the same busbars as the motor generators. The battery consists of 344 H-29 Exide cells, 72 of which are end cells. When discharged at the 1 hr. rate the battery has a rating of 1350 kw. and at the 20 min. rate a rating of 2700 kw. Diagrams of circuit connections are shown.

I. C. MATTHEWS.

The effect of porosity on the capacity of lead battery plates. C. HEIM. *Elektrotechn. Z.* 36, 281-2(1915); see C. A. 9, 2839.

C. G. F.

The overshooting in tungsten lamps. A. G. WORTHING. Nela Res. Lab. *Lighting J.* 3, 256-7(1915).—By means of a pendulum device the eyepiece of a Lummer-Brodhun photometer could be exposed at any desired instant following the closing of the circuit containing the lamp under investigation. A diagram of connection is shown. A high degree of accuracy was not possible. In vacuum W lamps a small amt. of overshooting was observed, due to the central portion of the filament reaching its max. steady temp. before the portions near the end. In N-filled W lamps the overshooting was found to be about 6% in c. p. Curves are shown. The results of J. B. Taylor (1908) are discussed.

C. G. F.

Results obtained with nitrogen-filled lamps. RAY PALMER. *Elec. J.* 12, 225-6(1915).—N-filled W lamps (325 watt) with compensators have been used satisfactorily to replace white flame arc lamps (465 watt). The c. p. of each is about 600. It is estimated that 15000 W lamps will have been installed by the end of 1915. The total cost per year for maintenance and operation is \$50.32 for the 465 watt flaming arc lamp and \$40.66 for the 325 watt N-filled W lamp. Details of cost and advantages are given.

A. B. GLADDING.

Arc lamp versus half watt tungsten lamps. A. CHEVALIER. Bremen. *Elektrotechn. Z.* 36, 269-70(1915).—Cost figures are given to show that for street lighting the modern arc lamp is cheaper than the N-filled W lamp.

C. G. F.

The new gas-filled tungsten lamps. M. PIRANI AND A. R. MEYER. Berlin. *Elektrotechn. Z.* 36, 492-6, 507-10(1915).—Detailed description of the new N- and A-filled W incandescent lamps. Numerous cuts and curves are shown. From 14 to 22.8 lumens per watt are obtained with these new lamps as compared with 3.2 lumens for the C filament, 6.0 for the Nernst lamp and 9.3 for the 1 w. p. c. vacuum W lamp.

C. G. F.

Manufacture of tungsten wire. St. *Elektrotechn. Z.* 36, 477-8(1915).—A review of present patented processes, in particular the Siemens and Halske Ni-alloy process, and the General Electric process.

C. G. F.

Electrical porcelain. Discussion. A. O. AUSTIN, *et al.* *Proc. Am. Inst. Elec. Eng.* 34, 2622-45(1915); cf. C. A. 9, 2035.—A. discusses methods of testing insulators as now applied and considers the weak field alternator method to be the best high frequency or impact method for commercial work. Photographs of various types under load are given. The short-time test at a higher voltage was considered best. The mechanical stresses are more to be feared than the elec. CROSBY FIELD-FRANK recommends the use of the oscillatory transformer as giving the most satisfactory and definite tests. P. W. SOTHEMAN recommends that more tests be made during mfg. and in the unglazed condition. The relation between flash-over and puncture must be very carefully considered. L. L. ISRAEL says that the dielec. hysteresis in material is of prime importance and that accidental flaws are secondary. R. P. JACKSON gives results of tests of the comparative value of the Tesla coil scheme, the high voltage impact scheme and the test under oil at normal frequency, all compared with ordinary flash-over test at normal frequency. A reasonably good insulator which will stand the 60-cycle test will stand up for a long time at high frequency which does not flash

over the insulator. There is apparently some residual mol. stress that lasts an appreciable time after the main stress is applied. Owing to a similar stress in the same direction a few secs. later, the torque or resisting power is already braced to receive it and the insulator stands. If the stress reverses this mol. stress, the insulator fails. J. C. SMITH, H. J. RYAN and J. S. LAPP also discuss the paper dwelling upon the nature and application of various tests. W. E. RUDER.

Electrical characteristics of solid insulations. F. W. PECK, JR. *Gen. Elec. Rev.* 18, 1050-7(1915).—Among the solid insulations used in practice are varnished cambric, oiled and varnished press board, treated paper, treated wood, mica, micanite, soft and hard rubber, synthetic resins, glass and porcelain. The actual resistance of the insulating material is very high but practically all solid insulating material absorbs moisture to a greater or less extent. The capillary tubes and microscopic interstices, etc., in the structure become filled with moisture and gases; these afford conducting paths through the insulation. The result is, in effect, a complicated arrangement of resistances and capacities in series and multiple. With a. c. the effective resistance varies with the frequency. With solid insulations loss appears as soon as the voltage is applied. This loss (ρ) may be due to so-called dielectric "hysteresis" or lag of the flux behind the e. m. f. due to some mol. action or it may be due to conduction through the absorbed moisture. Equations are derived and curves are shown for loss in good and in poor insulation. Plotting $\sqrt{\rho}$ against the gradient, kilovolts per mm. (effective) results in a straight line, showing that the square law is followed. The puncture ρ varies greatly with the time of application. This variation is due principally to heating where the time of application is comparatively long. Other factors, such as mechanical design, operating temp., etc., are considered at length. C. G. F.

Insulator performance from operating viewpoint. E. P. PECK. *Elec. World* 66, 1077-9(1915).—P. cites a number of cases due to defective insulators. He describes tests for weeding out faulty units, interpretation of high frequency effects and practical features of testing insulators. C. G. F.

Comparison of calculated and measured corona loss curves. Discussion. J. B. WHITEHEAD, *et al.* *Proc. Am. Inst. Elec. Eng.* 34, 2620; cf. *C. A.* 9, 2487.—W. argues that the losses on smooth wires would begin at E_s not with a sudden increase to a value represented on one of F. W. Peek's curves but gradually from 0 on a smooth curve. The difference between this theoretical curve and Peek's is due to weathering and surface irregularities. Peek shows that the disruptive critical voltage E_0 was not detd. by a single reading on an unstable part of the curve but from readings extending over the whole curve. W. E. RUDER.

The discharge tube used as a wireless valve. G. W. WHITE. *Electrician* 76, 103(1915).—A "gas valve" is described which consists of two ordinary electrodes fixed opposite one another and maintained at a high p. d. in a rarefied gas. To obtain the big current necessary for convenient values of p. d. a large vessel is employed and an intermediate electrode introducing only a low resistance. A glass tube 20 cm. long and 5 cm. diam. was used with an Al wire anode and an Al disk cathode fixed 6 mm. below the intermediate electrode. The Cu disk used for the intermediate electrode filled the cross-section and was provided with 3 holes of 1.3 cm. diam. The valve was effective up to 3 mm. pressure, but was best when the pressure was such that the edge of the "cathode dark space" was just 6 mm. from the cathode. Although the best conditions of operation have not yet been worked out, this app. has the advantage of dispensing with the heating filament and battery and is not sensitive to small pressure changes. W. E. RUDER.

Estimation of amount of nickel deposited on nickeled objects (PONTIO) 7. Controlling infra-red emission (COBLENTZ) 2. Gaseous-conductor lamp for color matching (MOORE) 25. The action of certain colloids or ions during electrolysis (MUTSCHELLER) 2. The relative migration velocities of the ions in complex electrolytes (MUTSCHELLER) 2.

Accumulator cells. VAN RADEN & Co. and M. METZ. Brit., 2,548, Jan. 31, 1914. The cells consist of Pb containing from 3.5 to 7.5% of Sb, and have glass covers. They may be cast, the smaller sizes in one piece and the larger and odd sizes in standard-sized halves, which can be burnt together after being cut down if necessary.

Electric liquid resistance. H. HERAPATH and M. J. RAILING. Brit., 15,798, July 1, 1914. In a liquid resistance, a conical electrode is provided with an insulated projection which enters a hole in the fixed electrode to prevent swaying. The projection may be of ebonite, or may be integral with the conical electrode and covered with ebonite.

Supports for incandescent filaments. G. LUDECKE and BRIMSDOWN LAMP WORKS. Brit., 27,157, Nov. 25, 1913. The supports consist of a Ni-W alloy, which may contain up to 50% of W.

Tungsten. BRITISH THOMSON-HOUSTON CO. Brit., 15,961, July 3, 1914. In the agglomeration of powdered W for the manuf. of wires and filaments, a mixt. is used of different varieties of substantially pure metal obtained from different chem. compds. The metal may be extd. from different tungstates, or a mixt. of different varieties of tungstic oxide prepd. in the following manner may be used. W_2O_5 is mixed with K_2CO_3 and Na_2CO_3 and KNO_3 and $NaNO_3$, and H_2O , to form a paste which is heated on an Fe plate to about 500–600°; it is then worked with a spatula and heated to about 900° directly by a gas flame. The product is dissolved in H_2O , and the soln. filtered, and W_2O_5 is pptd. by HCl and then dissolved in NH_4OH . From 1 part of this soln., NH_4 tungstate crystals are formed either by neutralizing with concd. HCl, or by playing a gas flame directly upon the soln., and the crystals are dried and ignited at about 450° to produce W_2O_5 . From the other part of the soln., W_2O_5 is pptd. by neutralizing with HCl, and then adding the whole to hot HCl. The 2 varieties of oxide thus obtained are mixed and reduced to W powder, which may be worked into wire in the manner described in 21,513, 1906, and 23,499, 1909; or a compressed mixt. of the oxides is heated in an elec. furnace to about 900–1100° and then powdered and reduced by H at about 900°, the product being suitable for making filaments in which the tendency towards offsetting is reduced.

Tungsten. PINTSCH AKT.-GES. Brit., 16,620, July 11, 1914. A rod, wire, ribbon, filament, or the like of a metal, *e. g.*, W or a W alloy, consisting throughout its whole length of a single crystal or of several crystals lying side by side and each extending through the whole length of the body, is obtained by passing the filament, etc., through a short zone of very high temp. at a speed not greater than that at which a crystal can grow and absorb or dissolve the succeeding portions of the material. The temp. of the hottest zone may be about 2400°, and the speed about 15–16 ft. per hr. for filaments suitable for incandescent elec. lamps. App. is specified.

Smelting furnace. F. J. MACHALSKE. Brit., 15,455, June 27, 1914. The hearth and lower parts of the side walls of the furnace are lined with artificial graphite which is not attacked by molten Fe, while the upper parts are lined with magnesite.

Smelting furnace electrode. F. J. MACHALSKE. Brit., 15,456, June 27, 1914. The electrode is movable and consists of 1 or more longitudinal C rods enveloped by a

refractory basic slag-producing compd. of Mg becoming conductive when heated. The total cross-sectional area is large in comparison with the area of C.

Smelting iron ore. F. J. MACHALSKY. Brit., 15,457, June 27, 1914. The ore is smelted with lime and artificial graphite, a metal free from C being obtained. The process is carried out in an elec. furnace, preferably lined with artificial graphite as described in 15,455, 1914 (*supra*), and electrodes composed of C rods surrounded by a filler of MgO or dolomite, as described in 15,456, 1914 (*supra*). Cf. C. A. 9, 2488.

Carbon-zinc element with manganese dioxide as depolarizer. COLUMBUS-WERKE, G. M. B. H. Ger., 284,144, May 10, 1914. In elements wherein the C electrode is imbedded in a graphite-MnO₂ mixt., the voltage falls rapidly during discharge. A marked improvement in the discharge curve is secured by an admixt. of CuO with the graphite-MnO₂ mixt. Experience indicates that the best action is obtained by an addition of 0.25-0.3% of CuO.

Electric accumulator. BRUCE FORD. Ger., 283,833, Apr. 28, 1914. The accumulator is provided with tubular insets for charging and removing gas.

Positive electrodes of alkaline accumulators. SVENSKA ACKUMULATOR AKTIEBOLAGET JUNGNER. Ger., 284,044, July 25, 1913. See Brit., 1,062 (C. A. 9, 1721).

Regenerating positive electrode masses. SVENSKA ACKUMULATOR AKTIEBOLAGET JUNGNER. Ger., 284,567, July 26, 1913. See Brit., 72 (C. A. 9, 1585).

Securing electric heating resistances on vessels. THERMOS AKT.-GES. Ger., 284,942, Dec. 6, 1914.

Alkali metals and their alloys. BADISCHE. Ger., 284,742, Jan. 6, 1914. In the electrolysis of alkali metal hydroxides, the alkali at the anode, which has taken up H₂O, is removed from the app. by the introduction of freshly dehydrated caustic alkali. The process is carried out with the use of a cell which is divided at the top into 2 or more compartments by 1 or more sepg. walls dipping in the electrolyte to a slight extent only. One of the resulting chambers serves to hold the products of the cathode, alkali metal and H, while the other chamber or chambers receive the O. The electrodes are opposed to each other under the sepg. wall, and they can be sepd. from each other by means of a wire gauze. The cell proper is provided with 2 nipples, of which the one on the cathode side serves for the introduction of the dehydrated alkali, while that on the anode side carries the H₂O-containing alkali from the cell, being traversed, therefore, by a current of alkali flowing from the cathode to the anode. The anode alkali, containing H₂O, cannot therefore enter the cathode chamber. The addition is regulated so that the current flowing in the cell is not strong enough to entrain the particles of metals rising from the cathode. The metal collects on the surface of the alkali in the cathode chamber. The accumulated metal either flows continuously from the cell, or is withdrawn from time to time. The fresh anhydrous alkali can be introduced through a nipple at the bottom of the cell, thereby effecting an exit at both the cathode and anode sides. NaOH or KOH or a mixt. of both may be employed.

Electrolytic deposits of iron and iron alloys. H. OTTINGER. Ger., 284,608, Dec. 1, 1912. The deposits are produced from baths containing alkali or alk.-earth carbonates or bicarbonates in amt. sufficient for neutralization. Attempts to obtain Fe ppts. heretofore have been attended with considerable difficulties, with the production of friable, porous, or off-color ppts. containing oxide. Better results are obtained now by the addition of H₃BO₃ to baths which have been neutralized in the usual manner by MgCO₃. Such baths yield, from the first, bright uniform ppts. By the addition of metal salts, alloys of Fe with Ni, Co, and other metals may be obtained of a good quality and of any desired thickness.

6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

Nitrogen compounds of gold. ERNST WEITZ. Univ. Strassburg. *Ann.* 410, 117-222(1915).—The 1st drop of NH_3 gives a permanent ppt. with HAuCl_4 . To complete the pptn. of the Au, 4 mols. NH_3 are necessary. The compn. of the ppt. is approx. $\text{Cl}:\text{Au}:\text{NH}_3$ or $\text{Au}:\text{N}:\text{Cl} = 1:1:1$. With 5 mols. NH_3 one obtains "fulminating gold" (A), in which the $\text{Au}:\text{N}$ ratio is 1:1.5, but which contains less Cl. More than 5 mols. NH_3 gives the same $\text{Au}:\text{N}$ ratio but continually decreases the Cl content. A is a mixt. of 2 compds., *sesquiammineauric oxide*, (B), $\text{Au}_2\text{O}_3 \cdot 3\text{NH}_3$, and *diamido-imidodiamineauric chloride*, or *imido-bis-amidoauric chloride*, (C), $\text{NH}(\text{AuNH}_2\text{Cl})_2$. B probably has the composition $2\text{Au}(\text{OH})_3 \cdot 3\text{NH}_3$ when air-dried. When A is treated with HCl it becomes considerably lighter in color, which may be due to the reaction with the acid, but no compds. could be isolated. The continued action of HCl leads to a product containing more Cl and less $\text{N} \cdot \text{NH}_4\text{Cl}$ has the same effect. Conc'd. NH_4Cl finally gives a soln. of NH_4AuCl_4 . A cold, fairly conc'd. soln. of NH_4CNS dissolves A in the cold. KI dissolves A slowly, in the cold, more rapidly when heated. *Diamido-gold chloride*, $\text{Au}(\text{NH}_2)_2\text{Cl}$, is obtained by treating 100 cc. of $\text{NH}_2 \cdot \text{NH}_4\text{Cl}$ soln. (100 cc. sat'd. NH_4Cl is treated with NH_3 until the vol. is about 150 cc.) with 40 cc. 0.2 N AuCl_3H containing 12 g. NH_4Cl , filtering after 2 days and drying without washing, yellowish red powder, containing 1 H_2O when air-dried. The dried product is not explosive. When washed with H_2O , more NH_3 is lost than Cl. The washed product is slightly explosive. The hydrated product may be $\text{AuOCl} \cdot (\text{NH}_3)_2$. B, in the hydrated form, is obtained by the action NH_3 upon A or D. It is very explosive, especially when dried at $105-110^\circ$ (loss of H_2O). If the product is mixed with 5 parts K_2SO_4 it is rendered non-explosive and can be dried at 105° . B is not affected by shaking with cold H_2O . Hot H_2O splits off $\frac{1}{2}$ of the N giving monoammineauric hydroxide (see below). Conc'd. NH_4OH has little effect. HCl dissolves it, forming AuCl_3 . Dil. H_2SO_4 and HNO_3 produce little effect in the cold; warmed, these acids split off NH_3 giving explosive products. Alkalies behave in the same way. B, dried to $115-120^\circ$, loses H_2O and gives *diamminetriaurous oxide*, $\frac{1}{2} \text{Au}_2\text{O}_3 \cdot 2\text{NH}_3$, black, very explosive. Heated with H_2O this slowly evolves N, giving metallic Au. *Monoammineauric oxide*, $\text{Au}_2\text{O}_3 \cdot 2\text{NH}_3$, is obtained by the action of hot H_2O upon B or better from AuCl_3 and excess NH_3 by digesting the pptd. B on the H_2O -bath with H_2O for 25 hrs.; it is a yellowish brown product which explodes when air-dried by simple rubbing. With NH_3 it gives B. By boiling with dil. HNO_3 all the NH_3 is gradually split off. HCl decomp. it into AuCl_3 , but the presence of a definite intermediary product was established. The action of NH_3 upon $\text{Au}(\text{OH})_3$ gives products with a $\text{Au}:\text{N}$ ratio of about 1:1, the amt. of N increasing with the time of reaction. *Tetrammineauric nitrate*, $\text{Au}(\text{NH}_2)_4(\text{NO}_3)_3$, is prepd. by passing NH_3 gas into a mixt. of 50 cc. sat'd. NH_4NO_3 and 20 cc. 0.2 N AuCl_3 soln. containing 40 mg. solid NH_4NO_3 until the liquid is only slightly yellow or until crystals begin to separate. After 24 hrs. the product is filtered, washed once with H_2O and dried with alc. and Et_2O . It forms glistening needles, which decomp. when heated. One g. H_2O dissolved 0.0288 g. at 25° . One g. 0.1 N KNO_3 soln. dissolves 0.0197 g. at 25° . A soln. of the nitrate gives cryst. ppts. with nearly all nitrates, which consist largely of the unchanged nitrate. With K, Na and NH_4 double salts are obtained. *Potassium salt*, with 1 KNO_3 , fine, long needles. *Sodium salt*, by mixing 0.8 g. nitrate in 25 cc. H_2O and 30 g. NaNO_3 in 25 cc. H_2O , fine, short needles. *Ammonium salt*, long needles. *Phosphate*, $\text{XPO}_4 \cdot \text{H}_2\text{O}$ (X = $\text{Au}(\text{NH}_2)_4$), fine white ppt. obtained by treating the nitrate in H_2O with $\text{Na}_2\text{P}_2\text{O}_7$ or Na_2HPO_4 , very difficultly sol. in H_2O , easily in dil. HCl or HNO_3 . *Oxalate nitrate*,

$X(\text{COO})_2\text{NO}_2$, is pptd. by $(\text{COONH}_4)_2$ as a fine difficultly sol. ppt. A normal oxalate could not be prepd. *Perchlorate*, $X(\text{ClO}_4)_3$, compact prismatic needles; 1 g. dissolves in 0.35 g. H_2O at room temp. *Oxalate perchlorate*, $X(\text{COO})_2\text{ClO}_4$, very fine leaflets. *Chlorate*, $X(\text{ClO}_3)_2 \cdot 2\text{H}_2\text{O}$, from the perchlorate and KClO_3 , very thin leafy needles, easily sol. in H_2O . *Iodate*. *Sulfate*, $X(\text{SO}_4)(\text{NO}_2)\text{H}_2\text{O}$, 4-sided tables. A 2nd product with 2 H_2O was also obtained. An *acid sulfate*, $X_2(\text{SO}_4)_4(\text{SO}_4\text{H})$, was obtained by the use of concd. H_2SO_4 . With the perchlorate 2 further sulfates were obtained, the *sulfate perchlorate*, $X_2(\text{SO}_4)_4(\text{ClO}_4)_2 \cdot 4\text{H}_2\text{O}$, leaflets, and the *sulfate perchlorate*, $X(\text{SO}_4)(\text{ClO}_4) \cdot 2\text{H}_2\text{O}$. *Chromate*, $X_2(\text{CrO}_4)_2$, light yellow. By warming the aq. soln. to 100° these salts decompose, giving a very explosive, dark brown product which contains less than 1.5 NH_3 to 1 Au. The salts are sol. in alkali but attempts to isolate the base were not successful. With acids the salts gradually deposit a light yellow fulminating gold, which contains NO_2 , and is probably a mixt. of B with imido-bis-amidogold nitrate, $\text{NH}(\text{Au}(\text{NH}_2)\text{NO}_2)_2$. Salts of the halogen acids give mixt. of products containing the halogen and B. The constitution of these compds. and the cause of their explosive properties are discussed at length. C. J. WEST.

Some new rare earth compounds. A. J. GRANT AND C. JAMES. *J. Am. Chem. Soc.* 37, 2652-4 (1915).—*Terbium pyromucate*, $\text{Tb}(\text{C}_4\text{H}_7\text{COO})_3 \cdot 3\text{H}_2\text{O}$ was obtained by neutralizing an aq. soln. of the acid with $\text{Tb}(\text{OH})_3$. When the soln. was evapd., radiating crystals were formed which were very sol. in H_2O . *Terbium 1,2,4-bromonitrobenzenesulfonate*, $\text{Tb}(\text{C}_6\text{H}_2\text{BrNO}_2\text{SO}_3)_3 \cdot 10\text{H}_2\text{O}$, was obtained in a manner similar to the pyromucate, except that the soln. was evapd. to dryness, the residue treated with alc., and the remaining solid recrystd. from H_2O . It was a heavy white compd. made up of very fine crystals contg. 15.59% Tb_2O_3 (theory demands 15.49%). *Cesium-ceric chloride* was formed from CeCl_4 mixed with CsCl in aq. EtOH . A yellow ppt. formed, but did not appear to be any definite compd. A double nitrate of La with $\text{Fe}(\text{NO}_3)_3$ was obtained as flat, green, hexagonal crystals which were fairly stable in the absence of air, but formed a reddish brown basic ferric salt when exposed. Analysis corresponded to the formula $3\text{Fe}(\text{NO}_3)_3 \cdot 2\text{La}(\text{NO}_3)_3 \cdot 24\text{H}_2\text{O}$. *Lanthanum pyromucate*, $\text{La}(\text{C}_4\text{H}_7\text{O.COO})_3 \cdot 2\text{H}_2\text{O}$, and *yttrium pyromucate*, $\text{Yt}(\text{C}_4\text{H}_7\text{O.COO})_3 \cdot 3\text{H}_2\text{O}$, were also prepd. as above. *Terbium propionate*, $\text{Tb}(\text{C}_3\text{H}_7\text{COO})_3 \cdot 2\text{H}_2\text{O}$, was prepd. from the hydroxide and the acid, and formed thin, white, powdery voluminous crystals. The % of the normal oxide agreed fairly well with a formula contg. 2 mols. of H_2O . The citraconate and quinate were found to be very sol. substances. E. B. MILLARD.

Separation of yttrium from the yttrium earths. III. J. P. BONARDI AND C. JAMES. *J. Am. Chem. Soc.* 37, 2642-3 (1915); cf. C. A. 8, 1928, 2996.—Details of several further attempts to sep. Yt from the Yt earths by fractional pptn. methods. The only reagent which gave much success was $\text{K}_2\text{Co}(\text{CN})_6$. In a 2-fraction sepn. a quite pink fraction with an at. wt. of 97.2 and a nearly white one with an at. wt. of 91.3 were obtained. When 4 fractions were pptd. with the Co reagent and the 5th by adding $(\text{COOH})_2$ to the last filtrate, the first 2 fractions had at. wts. of 98.7 and 95.1, resp., and the others, in order, were 90.8, 88.2 and 90.5. The high at. wt. of the 5th portion may have been due to Nd, which was shown to be present by the spectroscope. This fraction, and also fraction 4, showed an entire absence of Er bands. Some difficulty was encountered in controlling the quantity of ppt.; further work with this reagent is in progress. E. B. MILLARD.

Derivatives of perceric oxide. II. C. C. MÜLCHER. *J. Am. Chem. Soc.* 37, 2645-52 (1915); cf. C. A. 9, 2844.—The prepn. of *perceric potassium carbonate* has already been described, but the method used in its prepn. could not be applied to the corresponding Na compd. By treatment of *perceric ammonium carbonate* soln. with solid Na_2CO_3 in excess and evapg. in a vacuum a compd. can be obtained which differs

in many respects from the K compd. Cerous ammonium nitrate is dissolved in an excess of satd. $(\text{NH}_4)_2\text{CO}_3$ to which H_2O_2 has been added and the mixt. stirred with a current of air or CO_2 until a max. depth of red color is obtained. The soln. and any undissolved residue are treated with solid Na_2CO_3 and transferred to a vacuum desiccator for 48 hours and evapd. Extn. of the paste with small portions of H_2O and subsequent cooling of the aq. ext. gave crystals of *perceric sodium carbonate* as much as 10 mm. long. The large crystals appear black and the smaller ones dark red. It is only sparingly sol. in cold H_2O , differing markedly in this respect from the K compd.; it effloresces in air more readily than the K compd., forming a light brown opaque compd. which retains the external form of the original crystals. Contact with moisture above 0° causes hydrolysis, and with large quantities of H_2O the compd. is completely decomposed, and a gelatinous orange-red ppt. is formed. Analysis showed the formula $\text{Ce}_2\text{O}_4(\text{CO}_3)_2 \cdot 4\text{Na}_2\text{CO}_3 \cdot 30\text{H}_2\text{O}$. An interesting relation is shown by writing the Na and K compds. as follows: $\text{Ce}_2\text{O}_4(\text{CO}_3)_2 \cdot \text{K}_2\text{CO}_3 \cdot 3(\text{K}_2\text{CO}_3 \cdot 4\text{H}_2\text{O})$ and $\text{Ce}_2\text{O}_4(\text{CO}_3)_2 \cdot \text{Na}_2\text{CO}_3 \cdot 3(\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O})$. *Rubidium perceric carbonate* and *ammonium perceric carbonate* may be prepd. by methods analogous to that for the K compd. (C. A. 9, 2844), though the latter compd. was not isolated in a pure condition. In the double perceric compds. prepd. so far, the metallic constituent other than Ce is a strong base and the acid radical is that of a weak acid; the simple salt which unites with the perceric complex is very sol. In cases in which analyses have been made the Ce is in the state of oxidation corresponding to CeO_2 ; half of the O combined with the Ce is available for wet oxidation under restricted conditions; $\frac{2}{3}$ of the total available O is peroxide O. E. B. M.

Reduction of nitric oxide by contact action of metals and metallic oxides. B. B. ADHIKARY. *Chem. News* 112, 163-4(1915).—On heating Au (prepd. by reduction of AuCl_3 by FeSO_4) in a tube in a KNO_3 -bath and passing a mixt. of NO and H (1:3 in all expts.) over it, traces of NH_3 began to form at 280° , and the action became quite perceptible at 290° ; with the bath at 335 – 345° the action was very rapid, the yield of NH_3 being almost quantitative. Passing the same mixt. over Au foil gave only traces of NH_3 . The same mixt. with reduced Ag gave traces of NH_3 at 390° , decided action at 400° ; at 430° the yield of NH_3 is quite large. Instead of Ag, silverized asbestos (asbestos soaked in AgNO_3 soln. and ignited) may be used. With reduced Fe the mixt. gave traces of NH_3 at 300° , the action being very rapid at 350° . On passing the mixt. over Mg powders (Merck) in a tube-heater only traces of NH_3 were obtained; with Zn-dust (Merck) the yield was almost quant. When the same mixt. was passed over Hg, heated to about 400° , no NH_3 was obtained. With Al powders (Merck) only traces of NH_3 were obtained; with Sn powders (Merck) the yield of NH_3 was almost quant. Pb foil melted and NH_3 was obtained only in small amts. Pb powders obtained by the reduction of PbO gave better yield of NH_3 ; the Pb, though melted, remained in the form of a number of sep. globules. Sb powders (Merck) gave NH_3 , but larger quantities were obtained when Sb powders were freshly prepd. by the reduction of Sb oxides by H. With powdered Bi the metal melted and no NH_3 was obtained, but when Bi powders were prepd. by the reduction of Bi_2O_3 and the mixt. passed over it, large quantities of NH_3 were obtained. With ZnO or CdO large quantities of NH_3 were evolved, but in the case of other oxides of Group II of Mendeleeff's table (e. g., BaO , MgO , etc.), no trace of NH_3 was obtained. When HgO was used it volatilized and no NH_3 was evolved. With the oxides of Al, B, and Si no NH_3 formed, but with the oxides of Pb, Sn, Bi, and Sb large amts. of NH_3 were evolved. When the mixt. was passed over Cr_2O_3 ammonia was produced; with MnO or MnO_2 large amts. of NH_3 formed, the MnO_2 being converted into MnO during the reaction Cf. C. A. 5, 1031; Sabatier and Senderens, *Compt. rend.* 114, 1429(1892); 135, 278(1902).

F. W. SMITH.

The question of the existence of a mono-ammoniacal silver nitrate. A. REYCHLER. *Bull. soc. chim. belg.* 28, 198-200(1914).—R. has detd. the amt. of AgOH which is pptd. when varying amts. of NH_3 are added to 1 mole AgNO_3 in soln.; the results are given in tabular form. The following balanced reactions are indicated on the assumption that AgNO_3 forms the complexes $\text{Ag}(\text{H}_2\text{O})_2\text{NO}_3$, $\text{Ag}(\text{NH}_3)(\text{H}_2\text{O})\text{NO}_3$ and $\text{Ag}(\text{NH}_3)_2\text{NO}_3$ in the dilns. investigated: (1) $\text{Ag}(\text{NH}_3)(\text{H}_2\text{O})\text{NO}_3 \rightleftharpoons \text{AgOH (pptd.)} + \text{NH}_4\text{NO}_3$; (2) $2\text{Ag}(\text{NH}_3)(\text{H}_2\text{O})\text{NO}_3 \rightleftharpoons \text{Ag}(\text{H}_2\text{O})_2\text{NO}_3 + \text{Ag}(\text{NH}_3)_2\text{NO}_3$. The 1st equil. formula is $[\text{Ag}(\text{NH}_3)(\text{H}_2\text{O})\text{NO}_3] = K\pi(\text{NH}_4\text{NO}_3) = Cp$ in which p is the number of moles of AgNO_3 which are transformed into AgOH. If the remaining available moles of AgNO_3 and NH_3 are indicated by $I - p - Cp$ and $n - p - Cp$, resp., then $(n - p - Cp)/2$ moles $\text{Ag}(\text{NH}_3)_2\text{NO}_3$ and $(n - p - Cp)/2$ moles $\text{Ag}(\text{H}_2\text{O})_2\text{NO}_3$ may be formed. The 2nd equil. formula is $[\text{Ag}(\text{NH}_3)(\text{H}_2\text{O})\text{NO}_3] = K[\text{Ag}(\text{NH}_3)_2\text{NO}_3][\text{Ag}(\text{H}_2\text{O})_2\text{NO}_3]$. The results indicate the existence of an aquo-ammoniacal AgNO_3 . H. S. PAINE.

7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

Soda lime as an energetic general reagent and its great chemical activity. I. GUARIESCHI. Extract from *Suppl. ann. all'enciclopedia di chimica*, Aug., 1915.—In a review of the literature of soda lime, G. discusses its history and uses in full. Expts. made by G. show that it is an excellent absorbent for Cl_2 , Br_2 , HCl , HBr , NO_2 and COCl_2 . It is most active as a reagent when freshly prepared and must be kept well sealed. H_2S is absorbed with evolution of heat, so much so that when diluted with air and passed over freshly prepared soda lime the latter becomes incandescent. Fresh soda lime absorbs 80-90 cc. of CO_2 in 10 min. Expts. show that soda lime prepared from CaO and a solution of NaOH is best for the absorption of CO_2 . Thus prepared, it is a much better absorbent for CO_2 than solid KOH . Expts. carried out with CO , pyrrole, indole, aldehydes, Et bromoacetate, benzyl bromide, chloroacetone and a number of ethers and nitriles indicate that, with the exception of the first two named compds., absorption occurs more or less completely. Because of its activity, G. concludes that soda lime is probably not simply a mixture but a definite compd.

having the formula $\text{Ca} \begin{array}{l} \text{OH} \\ \text{ONa} \end{array}$ or $\text{Ca} \begin{array}{l} \text{ONa} \\ \text{O} \\ \text{ONa} \end{array}$. Traces of Fe, Mn, etc., apparently act

as catalysts. Soda lime containing these as impurities is superior to c. p. soda lime as an absorbent for H_2S and CO_2 .

L. T. FAIRHALL.

Acidimetric titrations with phenolphthalein. FERRARO ANNIBALE. Genoa. *Boll. chim. farm.* 54, 257-8(1915).—The reddish coloration produced in aq. exts. of flour and alimentary pastes by the addition of N alkali solns. and phenolphthalein persisted for a considerable period, while the color produced in alc. exts. (prepd. by extg. with neutral alc. at 90°) faded quickly; the reddish coloration reappeared (even more distinct than at first) when distd. H_2O free from CO_2 was added to the alc. ext. which had been treated as above. Alkali phenolphthalate is apparently less stable in alc. than in aq. soln. Alc. exts. such as the above should, therefore, be dild. with approx. twice the vol. of H_2O before titrating with phenolphthalein as indicator.

H. S. PAINE.

Methylene blue and its use in analytical chemistry. I. F. W. ATACK. *J. Soc. Dyers Colourists* 31, 183-90(1915).—Methylene blue is characterized (1) by great

fastness to light, (2) by the stability of its acid soln. and that of its leuco compd., (3) the relative ease by which it is converted quant. into its leuco compound by reducing agents in acid solns. and *vice versa* by oxidizing agents, and (4) its high tinctorial power, 0.002 *N* solns. being sufficiently colored for titration. A description is given of various salts of methylene blue, methylene blue hydrochloride and base, also of leuco methylene blue and its prepn. II. *Ibid* 203-8.—The use of methylene blue in qualitative analysis depends on one of 3 processes: (1) Reducing agents are detected by the manner in which they reduce methylene blue soln. to the colorless leuco compd. (2) Oxidizing agents are detected by the production of methylene blue on their addition to the colorless solns. of leuco methylene blue obtained by adding titanous chloride to luke-warm solns. of methylene blue until it is just decolorized. (3) Neutral salts of certain inorganic acids give characteristic precipitates with methylene blue solns. Less than 0.01 mg. of a titanous salt and 0.002 mg. of a molybdenum salt may be detected by methylene blue soln., also vanadous, chromous, tungstous, stannous and cuprous salts. Methylene blue is reduced by the salts of all of the lower sulfur acids, and by hydrazine hydrate, phenylhydrazine and alkali pyrogallate but not quant. in any of these cases. Oxidizing agents destroy methylene blue, the color not being regenerated by reducing agents. Chlorates but not perchlorates oxidize leuco methylene blue. On account of the slow end point in the cold and the fact that it is destroyed by free Cl, the use of methylene blue as an indicator is somewhat limited. It may be used in place of starch. 0.02 *N* methylene blue soln. is generally used for quant. purposes. It must be free from a reddish violet product which makes the end point indefinite, leading to an error of two or more drops in titrating. Methods for standardizing are given and its use in the following estimations is discussed: reducing agents, oxidizing agents, potassium, dissolved oxygen, nitroso compounds, quinones, azo compounds, diketones and oximes. L. A. OLNEY.

Gas analysis with the Bunte buret. ANON. *Z. Beleuchtungsw.* 20, 334(1914).—Ab-der-Halden has made expts. which indicate that appreciable amts. of CH_4 , C_2H_6 and higher homologs are absorbed by Cu_2Cl_2 soln. For this reason the eudiometric method is recommended for the detn. of CO and CH_4 . The analysis of a sample of illuminating gas by both methods shows CO 8.4% by absorption in Cu_2Cl_2 soln. and 5.1% by the eudiometer. The corresponding values for CH_4 are 28.3% and 30.6%, indicating that some CH_4 is absorbed by the Cu_2Cl_2 soln. and counted as CO.

A. B. GLADDING.

The determination of hydrogen in gas mixtures by catalytic absorption. E. BOSSHARD AND E. FISCHLI. *Z. angew. Chem.* 28, I, 365-6(1915).—As a substitute for the expensive Pd absorption process in technical gas analysis, the authors propose a method based on the principle of the hydrogenation of unsatd. oils with Ni as the catalyst. Using the Hempel app., absorb CO_2 , unsatd. hydrocarbons, O_2 , and CO as usual, avoiding yellow P for O_2 since it poisons the Ni. For the absorption of H_2 use two pipets filled with concd. Na oleate containing 3% Ni, prepared by reducing Ni_2O_3 in a stream of H_2 at 340° . Shake the sample (15-20 cc.) in the first pipet for 3 min. under diminished pressure, pass it to the next which contains 1 cc. EtOH to prevent foaming and again shake for 3 min. N_2 and CH_4 do not interfere. The latter is detd. by explosion. Comparative tests show the method to be highly accurate.

H. L. OLIN.

Estimation of traces of carbon monoxide in air. A. GAUTIER. *Bull. soc. chim.* 17, 256-60(1915); *Analyst* 40, 451(1915).—In view of a recent paper by Graham and Winmill (*C. A.* 9, 183) on the detn. of CO, G. states that he used the I_2O_5 method for the purpose in the year 1890, and that the reaction has been described by Ditte (*Bull. soc. chim.* 13, 318(1870)). G. found that the reaction between CO and I_2O_5

commences at 35°, and is rapid and complete at 75°; further, C_2H_4 , C_2H_6 , and the vapors of C_2H_5 and alc., when present in air to the extent of 1 part per 1,000 of air, are oxidized partially by I_2O_5 , and at the same time interfere with the oxidation of the CO. When the gases mentioned are present in quantity not exceeding 1 part per 100,000 parts of air, they do not affect the oxidation of the CO, nor are they themselves oxidized to any appreciable extent. Cf. *C. A.* 7, 1460 (Gautier), 8, 1938 (Seidell), 1939 (Moser), 2173 (Herman), 2474 (Sinnatt); 9, 1287 (Proboese). F. W. S.

Rapid estimation of amount of nickel deposited on nickered objects. M. PONTIO. *Compt. rend.* 161, 175-7 (1915).—**Reagent:** 50 cc. H_2O , 10 cc. HNO_3 (36° Bé.), 20 cc. HCl (22° Bé.), and 20 cc. of H_2O_2 (12 vol.). **Method:** Immerse the object for a few sec. in a bath of concd. H_2SO_4 , wash thoroughly, dry with a cloth, and place 1 drop of reagent on the surface; let stand exactly 2 min., then add 1 drop of NH_4OH (22° Bé.), let stand 1 min., and pour on a porcelain plate. A blue color indicates Cu as the base metal; brown or mauve indicates Fe. In doubtful cases, due to the color of the double salt of Ni, add 1 drop of $K_4Fe(CN)_6$ soln. The time of contact (3 min.) corresponds to a minimum of 1 mg. of Ni per sq. cm. for Cu objects, and to 4 mg. for Fe objects previously coppered. The necessary time of contact for other amts. of Ni on Cu or Fe may be detd. by expt., and the method may be applied to Ag on Cu or brass.

F. W. SMITHER.

Determining carbon in cast steel rapidly. W. L. MORRISON. *Foundry* 43, 151 (1915).—In order to control the C in elec. furnace steel a rapid method for the detn. was worked out. Color C does not work on alloy steels, so gravimetric detn. was necessary. Burn the steel in O by direct combustion and pass the CO_2 into an absorption bulb ~~connected~~ connected to the combustion train by a very pliable light-walled tube. The bulb ~~is~~ tube passing through the balance case. The tube droops a little so as to allow free swinging of the balance without exerting much torsional strain. A cheap grade of balance is used so that this slight torsion will not depress the balance pan. Take a half ~~factor~~ ^{weight} of drillings, place on granular alundum (90-mesh) in an alundum boat, ~~det.~~ The bulb weight and run in slowly with the elec. combustion furnace at 940° to 1000°. As soon as the steel begins to burn the O_2 flow is increased to the limit set by bubbling in the bulb. The burning takes 1 to 2 min., according to the C content; 1 1/2 to 2 min. is required for complete absorption of the CO_2 . Weighing is done to a standstill on a slight swing. The detn. can be made in 4 to 6 min., depending on the content. The app. is run 24 hours per day, in 3 shifts of 8 hours. Combustions can be made in 8 hrs. The av. error is within 1 to 2 points of carbon. The balance is sensitive to 1/2 point. The app. has been used 2 years. H. W. G.

Detection and estimation of traces of phosphoric acid, especially in potable water. P. MURONGEA. *Luxemburg. Chem. Ztg.* 39, 781-2 (1915).—The reagent is prepared by adding a satd. aq. soln. of strychnine nitrate (about 80 cc.), little by little, to a filtered soln. of 40 g. $NH_4 molybdate$ in 100 cc. distd. H_2O in a 500 cc. Erlenmeyer flask, with violent shaking, until a slight turbidity remains. This soln. is then poured, with constant shaking, into 180 cc. concd. HNO_3 (1.4 sp. gr.), let stand overnight and stored in dropping bottles. To use: put 20 drops of the reagent in a clean test tube, add quickly 10 cc. of the H_2O to be tested and swirl quickly once. A cloudiness should appear in 30 sec. with very impure or hard H_2O containing 0.25 mg. P_2O_5 per l. more than 10 cc. H_2O is taken, 2 drops of reagent should be used for each cc. H_2O , drops if the H_2O is very hard. The limit of sensitiveness for ordinary H_2O is about mg. P_2O_5 per l., or 0.05 mg. P_2O_5 per l. if dissolved in distd. H_2O . None of the constituents of H_2O affect the test if the observation is made within 30 sec. To be "mineral" P_2O_5 in sweet wine ~~take~~ 0.33 cc. wine to 100 cc. with distd. H_2O

e. g., from proteins rich in cystine or tyrosine, peptones were obtained also rich in these substances and *vice versa*.

F. W. SMITHER.

Picramic acid as reagent for albuminous substances (OSTROMUISLENSKII) 11B. New indicator for determining hydrogen-ion concentration (LUBS) 11B. The action of certain colloids on ions during electrolysis (MUTSCHELLER) 2. The relative migration velocities of the ions in complex electrolytes (MUTSCHELLER) 2.

8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY.

Pressure as a factor in mineral and rock formation. JOHN JOHNSTON. *Geophys. Lab.*, Washington. *Neues Jahrb. Min. Geol.* 1915, II, 89-108.—A discussion of this problem is presented, and it is concluded that the importance of pressure as a factor in so-called physical changes, as for instance m. p. of a pure substance, has been over-estd., as contrasted with its influence on chem. changes, in systems of several components. Change of pressure affects the fields of stability of a system just as change of temp. or of total compn., and the extent of its influence is detd. by the compressibilities of the phases. In the discussion of the crystn. relations of a complex magmatic system the pressure as well as the manner of cooling must therefore be considered. Changes of pressure as well as of temp. can change the sequence and even the character of crystn., unless all the soly. curves are affected alike.

E. T. W.

Note on the colors of some alluvial diamonds. F. P. MENNELL. *Mineral. Mag.* 17, 202-5 (1915).—Alluvial diamonds found in gravels and sandy clays from the borders of the Somabula Forest in southern Rhodesia are almost invariably of a green shade in the rough state. This color is entirely lost in the process of cutting and polishing. Recently some yellowish and brownish stones were found, suggesting a relationship between the color of the diamonds and the matrix in which they were embedded. The coloration seems to be due to infiltration or permeation from without (presumably Fe compounds) after the stones were deposited in the gravels. The color is not the result of an incrustation as no effect is produced by prolonged immersion in HF, or by fusion with a mixt. of KNO_3 and $\text{Pb}(\text{NO}_3)_2$.

W. F. HUNT.

Note on the color and alteration of pyrrhotite. F. P. MENNELL. *Mineral. Mag.* 17, 205-7 (1915).—The "bronze-yellow" color usually assigned to pyrrhotite does not seem to be the original color of the unaltered mineral. Specimens from Rhodesia possessing a tin-white color assumed after several months the bronze-yellow color. Originally this mineral was formed under conditions of great heat and pressure, and the difference between these conditions and those prevalent at the surface may have caused the color change after its extn. Upon exposure to air and moisture pyrrhotite alters very readily to FeSO_4 . The formation of this salt in Au ores containing pyrrhotite prevents the use of the cyanide process on the raw ore, owing to absorption of O and the repptn. of the dissolved Au.

W. F. HUNT.

Origin and occurrence of certain crystallographic intergrowths [of copper sulfides]. J. SUGALL. *Econ. Geol.* 10, 452-62 (1915).—A microscopical study with polished sections showing the relationship between chalcocite and bornite. The latter is secondary and derived from the former. Photomicrographs are given.

A. A. KLEIN.

A critical discussion of the crystal forms of calcite. H. P. WHITLOCK. *Proc. Am. Acad. Arts Sci.* 50, 289-352 (1915).—In the discussion the method of developing normal series proposed by Goldschmidt has been adopted as a basis of comparison. W. concludes that the neg. rhombohedron $05\bar{3}1$ and the series of pyramids $11\bar{2}3$, $22\bar{4}3$,

4483 are more common than heretofore recognized, and that the portion of the principal zone Z_4 lying between the poles $p(10\bar{1}1)$ and $P(32\bar{5}1)$ is completely known.

A. WANDTKE.

Crystals of albite from Alp Rischuna, and pericline twins from La Fibbia, Switzerland. W. J. LEWIS. *Mineral. Mag.* 17, 178-89(1915).—Largely crystallographic; the results differ considerably from the measurements on Swiss albites recorded by Des Cloizeaux. Multiple twins according to both the Manebach and Pericline laws were noted. Analysis gave: SiO_2 68.28, Al_2O_3 19.95, CaO 0.45, Na_2O 11.35, K_2O 0.06, loss on ignition 0.10. sum 100.19.

W. F. HUNT.

The dispersion phenomena of albite from Alp Rischuna, Switzerland. S. KÖZU. *Mineral. Mag.* 17, 189-93(1915).—The Abbé-Pulfrich total reflectometer and Hilger's wave-length spectrometer were used to obtain the indices for different wave-lengths. $n_D = 1.5289$; $n_F = 1.5330$; $n_D = 1.5392$. Optic axial angle computed = $78^\circ 30.5'$; observed, $78^\circ 39'$. Five tables record observed critical angles and the corresponding n s and birefringences, and the dispersion of the optic axial angle.

W. F. H.

Quantitative study of certain perthitic feldspars. CHARLES H. WARREN. Mass. Inst. Tech. *Proc. Am. Acad. Arts Sci.* 51, 127-54(1915).—W. presents the results of a quant. microscopic and chem. study of 6 perthitic feldspars from granite pegmatites, and adds for comparative purposes the chem. and mineralogical compn. of 2 granite pegmatites reported by Mäkinen (*C. A.* 8, 1078). The optical and petrographic characters of the group and of the individual specimens are discussed at length, and a table given showing the results of micrometric measurements made to det. the relative amts. of microcline and albite in these specimens. In the following table of chem. compn., the localities of the specimens are: I. Perth, Ontario; II. Westfield, Mass.; III. Bedford, Ontario; IV. Mineral Hill, Penn.; V. Pike's Peak, Colo.; VI. Grafton, N. H.; VII. Tammela, Finland (Härkäsaari); VIII. Tammela, Finland (Pakkalanmäki).

	I.	II.	III.	IV.	V.	VI.	VII.	VIII.
SiO_2	66.50	65.00	65.10	65.30	65.00	65.34	65.05	64.96
Al_2O_3	18.40	19.50	19.13	18.83	19.21	19.08	19.19	18.91
Fe_2O_3	1.05	.35	.32	.15	.20	.18	.28	.43
MnO	tr.	tr.	tr.	tr.	tr.	tr.	tr.	tr.
MgO	.07	.05	.06	.05	.03	.06	—	—
CaO	.30	.30	.24	.28	.35	.27	.41	.32
K_2O	8.77	12.36	12.98	13.60	13.62	13.05	11.19	12.09
Na_2O	5.40	3.03	2.53	2.20	2.20	2.56	3.57	3.31
H_2O	.20	.26	.16	.30	.12	.20	.15	.18
Total	100.69	100.85	100.52	100.71	100.73	100.74	99.84	100.20
Sp. gr.	2.597	2.568	2.571	2.565	2.562	2.570	2.564	

Analyses I.-VI. are by W.; VII.-VIII. by Mäkinen. In addition a specimen of albite from Grafton, N. H., contained 1.78% K_2O and 9.98% Na_2O , its sp. gr. being 2.62. The mineral compn. of these alkali-feldspar intergrowths was detd. by chem. and micrometric analysis; the approx. compn. of the 2 mixed crystal phases—microcline and albite types—are given in tabular form. The origin of perthitic intergrowths is discussed at length. The older theory that the perthitic structure is due to the introduction of albite from without into a previously formed microcline or orthoclase crystal, is considered untenable, and the more recently proposed theory of Vogt, that the K and Na-Ca feldspars form a broken series of mixed crystals with a eutectic point between them, is held to offer a satisfactory basis on which to explain their relationships.

L. W. RUGG.

The alkali-free aluminous augites. H. E. BORKE. Frankfurt. *Centr. Min. Geol.* 1915, 422-31.—A continuation of the discussion (C. A. 9, 2045; Tschermak, C. A. 9, 2496). The equation $p = q + r$ ($Si = Ca + Mg$), regarded by Tschermak as characteristic of augites, is based on av. analyses, but B. here shows by a table of the actual analyses that it does not hold for the individual ones, the difference between p and $q + r$ ranging from + 11.85 to -5.0. Projections of the analyses into tetrahedral diagrams show clearly that these relations are due to the formation of mix-crystals.

E. T. W.

The origin of the nephrite and the "carcaro" of Harzburg. J. FROMME. Egelu. *Centr. Min. Geol.* 1915, 432-45.—An elaborate review of the phenomena of nephrite formation, with criticism of the work of Uhlig (C. A. 5, 1384; 9, 1160). The geological occurrences, microscopical structure, and chem. compns. of the various nephrites are described in detail, and the conclusion reached that the mineral forms from serpentine, in part through the intermediate rock known as carcaro. In other regions, however, formation from diallage and diopside has been demonstrated.

E. T. W.

Natrolite crystals from Hesse. O. R. S. POPOVICI. *Bull. sci. acad. roumaine* 3, 147-57; *Chem. Zentr.* 1915, II, 39-40.—Crystals from the collection of Ochsenius, found in basalt amygdules, agree with those described by Lacroix from Puy de Dome, which certainly are rhombic. Twinning may be present if the mineral, as has been suggested, belongs to the monoclinic system, but optical tests appear to exclude this.

W. B. JOHNSON.

Childrenite from Crinnis mine, Cornwall, and eosphorite from Poland, Maine. JULIEN DRUGMAN. *Mineral. Mag.* 17, 193-202 (1915).—Penfield has shown that the same general formula applies to both minerals— $2(Mn, Fe)(OH)_2Al_2O_3P_2O_5 \cdot 2H_2O$ —childrenite possessing Fe as the bivalent metal, while in eosphorite Mn predominates. Childrenite occurs as minute crystals on the walls of narrow cracks in killas, sometimes also on quartz. Color, pale buff to almost colorless. The mineral was freed from the adhering matrix by careful mechanical sorting followed by digestion for a short period in warm, concd. HCl. The P_2O_5 was pptd. after dissolving the ignited material in acid, and the analysis continued in the presence of the molybdate giving: P_2O_5 29.80, Al_2O_3 21.20, FeO 28.30, MnO 3.35, CaO 0.90, Na_2O 0.25, H_2O 15.30, insol. 0.95, sum 100.05. The crystals are not suitable for accurate measurements; however, 5 forms were noted. Eosphorite: Material is from the Holden Collection, now in the Harvard Mineralogical Museum, its matrix is largely rhodochrosite and a black oxidized Mn compound. It forms small, radiated aggregates of prismatic crystals. Color, pale pink. Crystallographically and chemically it is very similar to the Branchville, Conn. material. Six terminated crystals were measured. The calcd. axial ratios are $a:b:c = 0.7724:1:0.5126$. $a_p = 1.6430$, $\gamma_D = 1.6691$; $2E = 65^\circ 27'$.

W. F. HUNT.

New phosphates from Greifenstein near Ehrenfriedersdorf. F. SLAVIK. *Bull. intern. acad. sci. Boheme* 1914, 1-16; *Chem. Zentr.* 1915, I, 216-7.—Roscherite is a new monoclinic mineral occurring as short thick plates and also as slender prismatic and thin tabular crystals. Axial ratio $0.94:1:0.88$; $\beta = 99^\circ 50'$. The cleavage is perfect parallel to 001 and good 010 ; hardness = 4.5; sp. gr. = 2.916; $n = 1.625$; double refraction, medium. The childrenite-eosphorite group is most closely related. For the properties of jezekite and lacroixite cf. C. A. 9, 1160. Analyses of these minerals gave the following:

	P_2O_5	Al_2O_3	Fe_2O_3	FeO	MnO	CaO	H_2O	Na	Li	F	OH
Roscherite	38.00	13.75		10.13	14.47	11.43	12.17				
Jezekite	30.30	21.92	Trace			13.50		18.17	0.86	8.15	7.26
Lacroixite	28.83	18.87	Trace		8.43	19.46				6.53	

In addition Lacroixite shows, MgO, Trace; Na₂O, 14.92; Li₂O, Trace; +H₂O, 5.46; SiO₂, 0.95.

A. WANDTKE.

Bassetite and uranospathite, new species hitherto classed as autunite. A. F. HALLIMOND. *Mineral. Mag.* 17, 221-36(1915).—No less than 3 distinct cryst. substances have been included under the name of autunite. Although the chem. comp. of the three is probably alike (apart from the H₂O of crystn.), on account of their crystallographic and optical differences they are not to be included in one species. The name autunite is retained for the Autun mineral; in addition the two following names are suggested: **Bassetite**: (after the Basset mines in Cornwall) hydrated Ca- UO_2 -phosphate. Monoclinic, with $a:b:c = 0.3473:1:0.3456$; $\beta = 89^\circ 37'$. Twinned by parallel growth of a and c axes so that the faces b are parallel. Sp. gr. = 3.10; biaxial, $2E = 110^\circ$; negative, Bx_a normal to b ; $\beta = 1.574$, $\gamma = 1.580$; pleochroic, $\beta = \gamma$ deep yellow, α pale yellow. In desiccator the extinction angle increases to about 20° . **Uranospathite**: (in allusion to the elongated tabular habit of the specimens) a hydrous UO_2 -salt. Orthorhombic, pseudo-tetragonal. Twin axis perpendicular to (110), in cruciform groups; sp. gr. = 2.50. Biaxial, $2V = 69^\circ$; negative, Bx_a normal to c . $\gamma = 1.521$, $\beta = 1.510$; pleochroic, $\beta = \gamma$ deep yellow, α pale yellow. Becomes uniaxial in desiccator.

W. F. HUNT.

Enrichment of silver ores. L. G. RAVICZ. *Econ. Geol.* 10, 268-89(1915).—If only a small amt. of Ag occurs in mineral waters, calcite cannot cause pptn., while alkali carbonates ppt. Ag salts. Sulfo-salts of Ag are unstable in presence of hot alk. sulfides. FeSO_4 acting on Ag_2SO_4 or Ag_2CO_3 readily ppts. Ag as follows: $\text{Ag}_2\text{SO}_4 + 2\text{FeSO}_4 = 2\text{Ag} + \text{Fe}_2(\text{SO}_4)_3$ and $\text{Ag}_2\text{CO}_3 + 3\text{FeSO}_4 = 2\text{Ag} + \text{FeCO}_3 + \text{Fe}_2(\text{SO}_4)_3$.

A. A. KLEIN.

Processes of mineralization and enrichment in the Tintic District. W. LINDGREN. U. S. Geol. Survey. *Econ. Geol.* 10, 226-40(1915).—Jasperoids along the deposits were formed by the replacements of limestones and dolomites by colloidal silica which later crystd. (first depositional phase). Contraction and crushing of silica caused its brecciation and colloidal silica of second phase was deposited, later crystg. Development of barite, galena and other sulfides accompanied both these phases and during deep oxidation chalcocite and covellite were formed together with oxy-salts. Au was concd. in places at all levels in Cu mines by secondary processes involving development of free Cl and AuCl_3 . The rich Ag sulfides are probably all secondary and were formed during the oxidation. A shoot opened near the water level shows a Ag-rich ore composed of galena, pearcite, zincblende and marcasite, which was deposited later than the other ores.

A. A. KLEIN.

Ores of Gilpin County, Colorado. E. S. BASTIN. U. S. Geol. Survey. *Econ. Geol.* 10, 262-91(1915); cf. C. A. 8, 2139; 9, 1290.—The ores consist of Au-Ag ores, U ores (source of Ra), W, Cu and Ti ores which are not commercially valuable. The ore-bearing solns. were apparently alk. or neutral and were rich in alkaline earths. During the early stages of mineralization they were rich in Fe and SiO₂ and during later stages in Pb and Zn carbonates and bicarbonates. They also carried smaller amts. of Cu, As, Sb, Au, Ag, and locally Mn, SO₄, Ba, Te, F, U, and V.

A. A. KLEIN.

Pocket deposits of the Klamath Mountains, California. H. G. FERGUSON. U. S. Geol. Survey. *Econ. Geol.* 10, 241-61(1915).—Au occurs in small calcite lenses between meta-andesite and slate, calcite and slate, and also in small specks without any gangue. Au was deposited later than calcite and replaces it. Its origin is in the pyrite of the low-grade manganese quartz veins found in meta-andesite. It was dissolved by nascent Cl formed by the action of H₂SO₄ upon a chloride in presence of MnO₂. Later the calcite neutralized the Au-bearing solns. and Au was deposited.

A. A. K.

Problems in iron ore geology in Sweden and in America. P. GRIJER. *Econ. Geol.* 10, 299-329(1915).—A comparison of the geology of American Fe ore deposits with those of Sweden touching on their similarity with reference to structure and origin.

A. A. KLEIN.

Oriskany iron ores of Virginia. C. M. WELD. *Econ. Geol.* 10, 399-421(1915).—The Fe ores include all forms of hydrated oxides intimately associated with sand, chert and clay. The origin of these deposits has been ascribed to replacement processes, with the overlying shale as the source of Fe. It is here suggested that the Fe has to a great extent originated in syngenetic bog-iron deposits in the Oriskany sandstone and that replacement processes have later served merely to conc. and enrich such original deposits or else to transport their Fe to new environments. The shale has, however, no doubt furnished a supplementary source of Fe.

A. A. KLEIN.

Iron ore deposits on the northwest coast of Lower California. E. WITTICH. Mexico. *Centr. Min. Geol.* 1914, 389-95.—A geological description of extensive Fe-ore deposits occurring toward the west coast of the peninsula south of Ensenada. The ores comprize hematite, subordinate magnetite and martite, and rarely pyrite, and are regarded as hot spring deposits, much silicious sinter and similar material being associated. In the vicinity of Webb's House Ranch fissures in diorite are filled with Fe ores, here associated with considerable Cu. Two analyses of the Fe ores are given, showing them to be of good quality, Fe being around 60% and P and S very low.

E. T. W.

Ancient sedimentary iron ores of British India. C. M. WELD. *Econ. Geol.* 10, 435-52(1915).—Fe ores occur here (1) among ancient unfossiliferous sediments, (2) disseminated through granites and schists, (3) as concns. within areas of basic igneous rocks, (4) in coal measures, (5) in the form of surface laterites. Only the first type offers deposits of economic value. The ores are hematite and magnetite. They have resulted from primary sedimentation, being deposited as the hydroxide, and later being dehydrated and consolidated.

A. A. KLEIN.

Oil pools of southern Oklahoma and northern Texas. J. H. GARDNER. *Econ. Geol.* 10, 422-34(1915).—A geological description of the Healdton and Wheeler pools. All the oil pools show structural conditions which are similar and which explain the concn. of oil and gas in those districts.

A. A. KLEIN.

Oil regions of northwestern Mexico. V. R. GARFAS. *Econ. Geol.* 10, 195-225 (1915).—A thorough description of this region. Petroleum here seems to be a product of decompn. of the animal matter furnished by a marine fauna which perished gradually with the oscillation of the region. The Cretaceous limestones are impregnated with unaltered petroleum, which originated from slow decompn. of their animal matter.

A. A. KLEIN.

The content of rocks in volatile substances. Preliminary communication on the gases and sublimation products of the eruptive rocks of the granitic massif of Greece. G. P. PAMFIL. *Bull. sci. acad. roumaine* 3, 72-81; *Chem. Zentr.* 1915, II, 45-6.—Wholly glass apparatus for freeing, evacuating, and analyzing gas from minerals is described. Results from plagioclase, granulite, granite, gabbro, and tonalite are tabulated. The temp. was carried to 1150°. Notable quantities of O were found, and NH₃ was always recognizable.

W. B. JOHNSON.

New type of alkaline granitic rock, inclosing eucolite. A. LACROIX. *Compt. rend.* 161, 253-8(1915).—This rock is found in N. W. Madagascar opposite Nosy bé, west of the village of Ampasibitika. An extended petrographic description of the locality is given. The mineral in question has a sp. gr. of about 2.97. A complete analysis of this mineral was not made on account of the difficulty of separating it from other minerals. It was attacked by HCl giving a jelly which, according to Pisani, had the fol-

lowing compn.: SiO_2 , 40.0; ZrO_2 , 16.4; $(\text{Ce La Di})_2\text{O}_3$, 22.5; FeO , 5.6; MnO , 0.1; CaO , 6.1; Na_2O , 6.6; total, 97.3. The deficiency is attributed to Cl, F, or H_2O which were undetd. These results point to a ceric eucolite distinguished from known species by less SiO_2 , CaO and Na_2O , and a much greater proportion of cerium compds. This is compared with analyses of aegirite, eucolite, a coarse-grained zirconiferous pseudomorph, riebeckite rich in eucolite, and rockallite, the latter from Rockall, Ireland. On the basis of this study L. suggests a new type, *fasibitikiite* for these granites containing eucolite; this completes the series of lujavrites.

L. W. ROGGS.

Sulfide-bearing rocks from Litchfield, Connecticut. E. HOWE. *Econ. Geol.* 10, 330-47(1915).—The rocks contain pyrrhotite, pentlandite and chalcopyrite. Most of the sulfides sepd. from soln. at an early stage of the cooling of the magma, and small amts. continued to sep. until the magma had nearly all crystd. The sulfide masses, however, remained liquid until all the silicates had solidified. The concn. of the sulfide is attributed to differentiation of the magma before its intrusion.

A. A. KLEIN.

The Wurzel region, in lower Veltlin. H. P. CORNELIUS. *Neues Jahrb. Min. Geol.* 40 (Beil. Bd.), 253-363(1915).—A geologic and petrographic description of the igneous and metamorphic rocks of this region.

E. T. W.

Contributions to the paleontology and geology of Palestine. III. The petrography of Palestine and the Hedschas Province. M. BLANCENHORN AND ERNST FUCHS. Marburg. *Neues Jahrb. Min. Geol.* 40 (Beil. Bd.), 533-82.—Comprises petrographic descriptions of a number of igneous and metamorphic rocks.

E. T. W.

The basalts of the Kamerun region and of that between the Kamerun Mountains and Elephant Lake. DOROTHEA MIESCH. Berlin. *Dissertation*, Berlin, 1914; *Neues Jahrb. Min. Geol.* 40 (Beil. Bd.), 457-532(1915).—The feldspar basalts and related limburgites are fully described, 8 analyses and their projections into Osann triangles being given.

E. T. W.

Metamorphic studies. Convergence to mineral type in dynamic metamorphism. C. K. LEITH AND W. J. MEAD. *J. Geology* 23, 600-8(1915); cf. *C. A.* 9, 1735.—The formation of slates, schists, and some gneisses, by rock flowage, requires both mineralogical and chem. changes, and there is a convergence, both chemically and mineralogically, toward a few platy or columnar minerals, which give these rocks their lamellar structure. Anamorphism tends to produce mica, chlorite, and hornblende at the expense of other minerals. Likewise chem. changes take place, principally by the elimination of substances, but also by additions from without, towards that necessary for the production of these schist-making minerals. Examples are cited where anamorphism has resulted in marked chem. changes in the original rocks. These changes have been sufficient to make it impossible to use chem. compn. as a conclusive criterion for the identification of origin of schists and gneisses.

W. F. HUNT.

The garnets and streaky rocks of the English Lake District. J. F. N. GREEN. *Mineral. Mag.* 17, 207-18(1915).—The garnets (almandite) occur sporadically in every variety of igneous rock of the district, while the "streaks" are mainly confined to the rhyolite and quartz-keratophyre. Crystals of almandite sepd. from a basic andesite were analyzed and gave: SiO_2 35.90, Fe_2O_3 6.12, FeO 27.48, Al_2O_3 20.20, MnO 3.84, CaO 1.42, MgO 3.28, TiO_2 1.53, alkalis and loss 0.23%. The "streaks" constitute numerous dark parallel, linear marks which, when best developed, contain macroscopic quartz or pyrite. These marks are sections of parallel lenses, the direction corresponding with the bedding and in a general way, with the flow surfaces. The streaks originate as fine contraction cracks which in the more advanced stage become veinlets. The conclusion reached is that the garnet, pyrite, and streaky alteration have been

formed by circulating solns. under high hydrostatic pressure, probably during the sulfataric stage of the Borrowdale volcanic period. W. F. HUNT.

Detrital andalusite in Cretaceous and Eocene sands. G. M. DAVIES. *Mineral. Mag.* 17, 218-21 (1915).—Andalusite is a frequent constituent of the Eocene and Cretaceous beds of southeast England. Therefore the presence of this mineral can no longer be regarded as evidence of the Pliocene or post-Pliocene age of the deposit in which it occurs. W. F. HUNT.

The artesian wells of Montreal. C. L. CUMMING. Canada Dept. of Mines. Geol. Survey, *Mem.* 7, No. 60 (Geol. Series) (1915).—The data were obtained from 179 artesian wells. The scheme of classification of the waters that C. has devised is similar to that of Palmer (*C. A.* 5, 3869) but instead of summarizing the waters according to their reaction properties, C. classifies them on the basis of the chem. values of the individual constituents detd. and considers each individual an important factor. A graphic representation of these values is devised by which all the constituents are compared with one another. C. attempts thus to refer the waters to their geological sources, being enabled to do this on account of the peculiar geology of the region. He classes the waters as (1) "pure types" and (2) "mixed types." The 4 kinds of "pure type" waters are those in which the predominating inorganic constituents are (1) Na_2CO_3 , (2) Na_2SO_4 and NaCl , (3) CaSO_4 and MgSO_4 , (4) CaCO_3 and MgCO_3 . A "mixed type" of water is regarded as a mixture of "pure type" waters. The geology of the region is discussed in detail. Montreal derives its waters from the Laurentian highland and the St. Lawrence lowlands, though to what extent each of these contributes its share is not known. Na_2CO_3 is the chief inorganic material of the water and it is probably derived from the dike rocks cutting the limestone. The strong-acid salts represented by NaCl , Na_2SO_4 , CaCl_2 and CaSO_4 are derived from the country rock, into which these salts were probably injected at the time of the intrusion of the igneous rocks of Mount Royal. CaCO_3 is derived partly by direct soln. of the rock and partly by double decompn. of some of the above salts when waters containing them mingle with one another. H_2S is assumed to have been formed by reduction of sulfates through the agency of organic matter which occurs commonly in the Trenton limestone. Certain areas are characterized by waters in which the different "pure types" predominate. At the boundaries of these areas, which are largely detd. by the presence of dikes, the waters sometimes become mixed, thus yielding waters of complex properties. Often such waters contain, not the most sol. of the constituents involved, but the least sol. ones. In an attempt to explain this anomaly, C. is compelled to resort to the physical process of absorption or adsorption. A chart shows the peculiar relation of Mg to Na and Ca that as the Na increases the Mg increases at the expense of the Ca. The K content, so far as is known, is from 2-30% of the alkalis. W. C. WHEELER.

New and little known mineral springs of southeast Mährens. R. SCHUBERT. *Metall. Rundschau* 7, 65-8; *Chem. Zentr.* 1915, I, 503.—These springs form a group of more or less pure H_2S and alkali chloride waters whose source is the Miocene andesite, the Mesozoic limestone, and the Tertiary salt-bearing shale. The mineral waters at times well out of the coarse Flysch sandstone. The S springs of the Prerau region are related to blue and dark gray clay-schist and issue along fissures that cut the clay schist at right angles to the strike. Traces of natural oils occurring in the Flysch rocks may be indicative of petroleum deposits. A. WANDTKE.

Heating tests and the cause of disaggregation of granite. W. A. TARR. *Econ. Geol.* 10, 348-67 (1915).—Expts. on Missouri granites show that disaggregation as a result of heating is due to differential stresses set up in each individual mineral. These stresses vary in different directions because of different rates of expansion and find relief in cracks and fractures. The stresses are cumulative and affect the rock as a whole,

but differ in parts of it. The presence of inclusions especially of liquids and gases whether in rows or disseminated is not regarded as having any effect upon the resulting disaggregation, except in so far as a series of inclusions of any nature arranged along a plane in a mineral would make that plane a line of weakness that might be followed by a crack.

The present state of the flotation process of ore concentration. ANON. *Russ. Min.* 43, 41-4(1915).—A review.

L. T. FAIRHALL.

Thermal principles of the blast furnace. J. E. JOHNSON, JR. *Mel. Chem. Eng.* 13, 718-20, 787-92, 833-40(1915).—J. discusses the application of the second law of thermodynamics to the operation of the blast furnace. For every set of furnace conditions there is a critical temp. (about 1500°), above which only certain necessary operations such as the formation and superheating of the cinder and the melting and carbonization of the Fe can be carried on. It is evident, therefore, that the greater the range between critical temp. and theoretical temp. of combustion, the greater is the effective heat. Preheating and drying the blast raise the efficiency of the finishing operations in the bosh by raising the combustion temp., thus widening the zone of effective heat. The relatively high fuel consumption of furnaces working on rich ores is the result of the small slag-volume available for removing S, making necessary an increase in lime which raises the fusion temp. and with it the critical temp. The low consumption in the charcoal furnace is due to the absence of S, making possible a highly siliceous and fusible slag. For max. fuel economy, the ratio $H_a/(H_t - H_a)$, where H_a is the available heat above critical temp. and H_t the total heat per unit of fuel, must be maintained constant, since with a disproportionate increase in H_a there is a deficiency of ore prepared for final reduction, while an increase in H_t which does not effect H_a results in the preliminary heating of a greater quantity of ore than the bosh can care for, and a subsequent cooling of the latter, with attendant fuel losses. In the case of a charcoal furnace of high fuel consumption, using an ore with 13-14% H_2O , J. found that the $(H_t - H_a)$ factor, or the heat of shaft and top, was reduced abnormally by the evapn. of H_2O . By drying the ore, fuel consumption was reduced 12%.

H. L. OLIN.

Liquid jets. C. T. DU RELL. *Mel. Chem. Eng.* 13, 714-6(1915).—A study of a phenomenon of importance in flotation and cyanidation. The term "liquid jet" is applied by R. to a stream of liquid projected through a gas into a liquid. The liquid may be injected (1) vertically upward, (2) vertically downward, or (3) at an angle. The physical phenomena accompanying each of these methods is described. R. shows that in either case a jet of liquid turned into a gas does not merely slide through that gas or a cylinder of that gas but carries the "gas cylinder" along with it. When a liquid is entirely satd. with a gas brought in with a jet, supersaturation has the effect of producing nascent gas, which collects in the form of bubbles. This fact is taken advantage of for flotation, but while liquid-jet phenomenon has not been recognized before by many cyanide metallurgists it has been the direct cause of many cyanide

plant failures. R. doubts the existence of a single case of difficult slime settlement due entirely to a true colloidal condition as most pulp solns. are so supersatd. with air that they are more nearly ready for a flotation plant than they are for a cyanide plant.

C. A. NOWAK.

Reclaiming brass foundry waste. A. W. LEMME. *Foundry* 43, 191(1915); cf. C. A. 9, 1738.—Details of cupola refining of the concentrate from brass foundry sweepings.

H. W. GILLET.

Oxy-acetylene welding practice. S. W. MILLER. *Machinery* 22, 2159-(1915); cf. C. A. 9, 3212.—M. describes welding of malleable Fe and Cu and Cu alloys, brass and bronze. The metallurgy of Fe and its relation to welding, heat treatment of welded steel, and other factors are discussed.

C. G. F.

Comparison of thermite and electric welding. J. F. PERRITT. *Reactions* 8, 42-6(1915).—For repairing locomotive frames and other heavy sections thermite welding is more practical and cheaper than elec. welding. The paper is profusely illustrated.

C. G. F.

The heterogeneity of steels. H. LE CHATELIER AND J. LEMOINE. *Compt. rend.* 161, 373-8(1915).—The abnormal sepn. of pearlite in ordinary steels is generally attributed to the presence of P which lessens the soly. of C in Fe. But this effect of P is uncertain since it is not clearly shown that the sepn. of pearlite becomes normal in steels where the distribution of P is even. As a reagent for the direct detn. of the effect of P, a modified form of Stead's reagent was used; 100 cc. absolute CH_3OH , 18 cc. H_2O , 2 cc. concd. HCl , 1 g. CuCl_2 , 4 g. MgCl_2 . From this reagent Cu deposits on the portions poorest in P. Photomicrographs were obtained showing a remarkable striated structure. This banded structure can be obtained also in P-free steels containing Si, Mn, Ni and Cr; it is shown in nearly all steels, even those of good quality. The photographs show that the result of various treatments is not to destroy the banded structure but to render the structure more homogeneous and the bands narrower; this explains the advantages of tempering, etc.

DONALD BELCHER.

The constitution of brasses containing small percentages of tin. O. F. HUDSON AND R. M. JONES. Univ. Birmingham. *J. Inst. Metals* 12 (advance copy) 13 pp. (1915).—An account of work on that part of the ternary diagram for Cu-Zn-Sn alloys comprizing 50 to 70% Cu, 0 to 5% Sn and balance Zn. It cannot be briefly abstracted. Also in *Engineering* 100, 589-90(1915).

H. W. GILLET.

The comparison of the various tests for determining the hardness and wear of metals, and the development of a suitable machine for testing the wearing properties of cylindrical pins. T. E. STANTON AND R. G. C. BATSON. *Report Nat'l Physical Lab.* 1914-15, 101-2.—The relation between the Brinnell hardness number and the resistance to wear depends largely on the compn. of the steel. In ordinary C steels a resistance to wear 18-20 corresponded to a hardness number 720, while in Mn steels with resistance to wear 27-30 the hardness number was 241-286.

Protecting bright articles from rust (HASS) 26. The electric furnace in the foundry

(GRAY) 4. The chemist and the lead industry (THOMPSON) 26. Electrical heating and the Schoop metal spraying process (LACH) 1.

Cast iron. AKT.-GES. R. P. WAAGNER, L. and J. BIRÓ and A. KUTZ. Aust., 7,477, Oct. 31, 1914. Cast iron is manufd. in the cupola furnace by fusing together several kinds of Fe of varying C content. The furnace is charged, separately, with the different kinds of Fe, in order that the particular additions favoring the production of a definite special Fe and serving to lower the m. p., may be brought into reaction in the corresponding charges, whereby the melting process can be effected with a blast of a suitable vol. and under the most favorable pressure.

Concentrating ores. W. M. MARTIN. Brit., 15,442, June 27, 1914. The surface used consists of frosted or fluted or frosted fluted glass or other material such as brick tile or porcelain. When a fluted surface is used, it is stationary or has a continuous movement in the direction of the flow of the pulp.

Treating roasted ore with liquid. A. RAMEN. Brit., 15,254, June 25, 1914. The ore is delivered in a thin layer onto a bed moving below a perforated pipe which distributes the liquid evenly over the mass. The mixt. is removed from the bed for further treatment, and any gases, vapor, and dust resulting from the treatment are withdrawn to a wet condenser. The hopper which feeds the ore to a rotary table may be raised or lowered to vary the thickness of the layer. A casing enables the vapors, etc., to be led to a condenser, and the ore, after treatment, is discharged from the table by an inclined scraper. An endless belt, shaking-trough, cylinder, or other form of carrier, may be used.

Treating ore with liquid. A. RAMEN. Brit., 15,378, June 26, 1914. In spraying or mixing roasted ore with liquid on an impermeable moving bed, as described in 15,254, 1914 (*supra*), the quantity or quality of the liquid is chosen so that 1 or more components of the ore dissolve and form a soln. in admixt. with the other components. Sep. extrn. of the different values may afterwards be effected by a series of lixiviating operations. An ore containing Cu and Ag may be sprinkled after a chloridizing-roast and with a soln. of salt in sufficient quantity to dissolve the AgCl, and subsequent lixiviation with a chloride soln. will produce a concd. soln. of Ag with only a small amt. of Cu. Zn may be sepd. from Cu in a similar manner. The speed of the moving bed may be varied in order to control the quantity of liquid supplied to the ore.

Treating ores. H. W. C. ANNABLE. Brit., 15,962, July 3, 1914. Gang consisting mainly of the alk. earth carbonates is removed from ores, etc., by treatment with SO₂ under exclusion of air, and at a temp. not exceeding 40°. For this purpose, crushed ore is suspended in H₂O and a stream of SO₂ injected; or a soln. of the gas may be used. The Ni salt pptd. by means of MgCO₃ is ignited to form NiO and then treated with SO₂ to remove any Mg salt.

Steel and slag rich in soluble phosphates. DEUTSCH LUXEMBURGISCHE BERGWERKE-UND-HUTTEN AKT.-GES. and A. VOGLER. Brit., 27,868, Dec. 3, 1913. The process of manuf. by the basic open-hearth method comprizes the following stages: (1) the formation and removal of a slag containing part of the P, (2) the formation and removal of a second slag containing the remainder of the P, and (3) decarburizing. In the treatment of a silico-phosphoric pig, a silicious slag is formed during the first stage, the P being removed in the second stage. Cf. C. A. 9, 1299.

Steel. ROMBACHER HUTTENWERKE and J. I. BRONN. Brit., 2,385, Jan. 1, 1914. Alloys to be added to the metal bath are obtained by treatment of metal of similar compn. to the main body of metal, as described in 29,051, 1912, and are allowed to solid-

ify before use. Spiegel and Fe-C alloys are obtained by adding ferro-Mn, ferro-Si, carburite, etc., in solid form to a bath of refined Fe.

Copper-lead alloys. L. SAMPPELL. Brit., 28,492, Dec. 10, 1913. A molten bath of the metals is treated with HI gas to give a homogeneous product.

Casting metals. F. REICHARDT. Brit., 16,324, July 8, 1914. In a machine for charging under pressure, solid metal is fed in a continuous "string" to a completely closed melting pot and serves as a pressure piston for the molten metal. The melting pot is provided with electrodes and the inlet and outlet nozzles are Pt-lined.

Coating metals. F. J. DE LAET and S. COULIER. Brit., 15,566, June 29, 1914. The surfaces of metal plates to be cleaned and partly coated with metal are provided with a resist which will prevent the cleansing of the parts it is not desired to coat, and the protection of the resist or of its decompn. products may continue during the dipping. The resist may be composed of 1 or more of the following materials in their normal state, or in suspension or soln.: cellulose, amylaceous, albuminous, sugary, bituminous, or asphaltic substances, tars, gums, wax, resins, caoutchouc, fats or grease, gelatin, vaseline, paraffin, etc.; flour, starch, and paper are mentioned. The resist may be recovered before or during dipping. Plates may be partly covered with a layer of 1 metal, and the uncovered parts may subsequently be coated with another and more fusible metal; or plates may be coated with Sn and Pb on opposite sides.

Coating surfaces with metals. R. K. MORCOM. Brit., 15,960, July 3, 1914. In coating surfaces with metals and other fusible materials by spraying, the surface is preliminarily heated by 1 or more sep. leading jets and the deposit may be heated by a following jet for the purpose of effecting annealing or deoxidation. The spraying blowpipe and the jets are clamped to a cross bar so that their positions with regard to each other and to the surface may be adjusted; a combustible mixt. is supplied from a union. A flux, such as HgCl_2 or NH_4Cl , or a powdered reducing agent, may be used in connection with the leading jet. Cf. C. A. 9, 360.

Treating ore with nitric acid. H. BÜBLER DE FLORIN. Ger., 284,741, Oct. 22, 1912. The process is especially applicable to carbonate ores such as Cu carbonate and oxide ores containing lime and magnesia. N oxide gases, with or without H_2O , are used also, the ext. being evapd. to dryness and heated at a sufficiently high temp. to decompose a portion of the nitrates (*e. g.*, Fe and Cu nitrates, but not Ca and Mg nitrates). The partially decomposed dry residue is then extd. with H_2O for the purpose of obtaining a material rich in CuO and a $\text{Ca}(\text{NO}_3)_2$ lye. The HNO_3 lye can, however, be evapd. to dryness and the dry residue heated so long and at such a high temp. that all the contained nitrate is decomposed. The HNO_3 liberated upon decompn. of the nitrate is returned to the process. *E. g.*, the ore, ground to a fineness of at least 5 mm., is treated in extn. vessels with 7-12% HNO_3 , H_2O , and N oxide gases. The decanted or filtered lye, which may contain, besides $\text{Cu}(\text{NO}_3)_2$, also other sol. nitrates such as Zn-, Pb-, Ag-, Fe-, Al-, Ca-, or Mg-nitrates, can be worked further in various manners. *E. g.*, the nitrate lye is evapd., whereby a considerable portion of the Fe is pptd. and may be removed. Upon protracted heating to 300° , $\text{Cu}(\text{NO}_3)_2$ and any Fe- and Al-nitrates remaining in soln. are decomposed, while Ca- and Mg-nitrates remain unchanged and are extd. from the dry mass with H_2O . The residue now remaining, which contains all Cu as oxide together with Fe-, Al-, and other oxides, is suitable for smelting to metallic Cu and for the production of CuSO_4 . Or the evapd. nitrate lye is heated for a long time above 500° so that all nitrates, including those of the alk.-earth metals, are decomposed. The calcination residue may be smelted in the elec. furnace, by reduction, to metallic Cu. When Cu-free sulfide ores, such as Zn blende or galena, are to be smelted together with carbonate Cu ores free from S and rich in lime, the SO_2 -containing gases drawn

from the roasting furnace may be employed for evapg. and calcining the $\text{Cu}(\text{NO}_3)_2$ lye, or also, at the same time, for a partial decomp. of the lye before it is evapd. to dryness, so that any Ca, Pb, or Ag contained in the lye before calcination can be sepd. as sulfate. The Cu can be pptd. from the nitrate lye also by means of Fe, $\text{Fe}_2(\text{NO}_3)_6$ being obtained as a by-product, which decomposes, upon evapn. and calcination, into com. Fe_2O_3 and nitrous vapors. The $\text{Cu}(\text{NO}_3)_2$ can be subjected not only to cementation, but also to electrolysis, whereby metallic Cu and aq. HNO_3 result.

Mold. W. D. BRADFORD. Ger., 283,217, May 1, 1913. Structural features.

Zinc muffles. C. MEHLER, MASCHINENBAUANSTALT, G. M. B. H. Ger., 284,598, Nov. 13, 1913. Hydraulic press for their manuf.

Aluminium coating on lead. E. FRITSCH. Ger., 284,554, July 5, 1913. Addition to 282,899 (C. A. 9, 2378). In producing such coatings according to the parent process, Al powder is mixed with Sn, in equiv. wts., and in a finely pulverized state. An emulsion is then made with about 50 parts molten, pure, hard Manila and Borneo copal, to which 30 parts of linseed oil are added, so that a seedy mass results to which about 1% Mn and 0.5% Pb are added as a drier. Materials which upon heating oxidize or form slag cannot be added. The resulting emulsion is dild. with turpentine oil, alc., or the like. The metal powder specified above is stirred up with the emulsion and applied, by hand or machine, to the articles to be coated. The treated articles are then heated in a drying oven to about 200° . The added Sn also protects the Al from oxidation. Cf. C. A. 9, 2506.

Improving the magnetic properties of castings. LANGBEIN-PFANHAUSER-WERKE AKT.-GES. Ger., 283,670, Dec. 10, 1913. The articles are ignited in an atm. of H or of some gas containing H and not explosive.

Preparing manganese steel blocks for rolling. MANGANESE STEEL RAIL CO. Ger., 284,602, Nov. 26, 1908. The heat treatment to which this alloy is usually subjected fails to impart the required ductility, since the temps. have been below the upper critical point (between 1010 and 1050°). At this temp. the metal is resistant to a slight extent only, by reason of the sepn. of the eutectic alloy, which melts at 1125° and goes into soln. upon increase of temp. In order to prevent this, the blocks are heated, uniformly and by degrees, to a temp. above the upper critical point, until the eutectic alloy redissolves. Further heating, preferably to 1250° , is effected in a non-oxidizing atm. The highest temp. is fixed upon with reference to the analysis of the steel, the thickness of the block, and the mechanical process of working to which it is to be subjected (rolling, hammering, and the like). If a block is to be treated directly upon discharge from the mold and with the heat of casting, its temp. is increased or lowered in the soaking pit to the predetd. highest temp. The outer layer of the block is cooled, in a non-oxidizing atm., to the same or a lower temp. than that which prevails in the mass, in order to impart to the outer layer the resistance and toughness necessary for the mechanical working.

Burners for cutting metal. CHEM. FABRIK GRIESHEIM-ELEKTRON. Ger., 284,539, July 8, 1913. The gases are drawn from the same conduit.

Dies for drawing metal. ALLGEMEINE ELEKTRIZITÄTS-GES. Ger., 284,808, Feb. 7, 1913. The dies are manufd. from highly sintered, amorphous, difficultly fusible oxide such as Al_2O_3 . A formed mixt. of the difficultly fusible oxide is ignited with a binder which is volatilized at a temp. at which a slight sintering occurs (1300 – 1400° in the case of Al_2O_3), whereupon the stone is further shaped and ignited at a higher temp., below the m. p. (1800 – 2000° for Al_2O_3), at which temp. the product is completely sintered.

Cupola furnace. A. SAUER. Ger., 284,770, Dec. 12, 1913. The flue gases,

after leaving the melt, heat the fuel, in an extension of the shaft, wherein the fuel rests on a number of superimposed grates, the CO_2 being reduced to CO , with the production of water-gas.

Ludwig Medicus. FRITZ REITZENSTEIN. *Ber.* 48, 1744-8(1915); *Chem. Ztg.* 39, 837-8(1915).—Died Oct. 11. Brief reviews of his work, chiefly in org. chemistry. J. H. MOORE.

Adolf von Baeyer's eightieth birthday. H. WIELAND. München. *Chem. Ztg.* 39, 829-32(1915).—Oct. 31. A review of his work in org. chemistry. J. H. M.

The recent development of stereochemistry. M. SCHOLTZ. Univ. Greifswald. *Ber. pharm. Ges.* 25, 225-55(1915).—An address. W. O. E.

The root bark of *Calotropis gigantea*. ERNEST G. HILL AND ANNODA P. SIRKAR. Allahabad. *J. Chem. Soc.* 107, 1437-42(1915).—The milk-like sap is much used in India as a medicine. 4 kg. root bark, broken up and extd. with boiling 98% alc. for 3 hrs., gave 78 g. oil, 90 g. white solid (A) which sepd. partly on cooling and partly on concn, and a residue, which, when extd. with Et_2O and digested with H_2O , gave 330.5 g. gutta-percha-like residue and a small amt. of a yellow bitter principle. A long series of fractional crystns. from alc. of (A), identical with Warden and Waddell's "madar-alban" (*Pharm. J.* 1885, 165), gave, as the less sol. portion, *akundarol isovalerate* (B), $\text{C}_{14}\text{H}_{24}\text{OCO}_2\text{C}_4\text{H}_9$, needles, m. 210° , $[\alpha]_D^{25}$ 119° in Et_2O , and as the more sol., *mudarol isovalerate* (C), $\text{C}_{20}\text{H}_{37}\text{OCO}_2\text{C}_4\text{H}_9$, nodules, m. 140° , $[\alpha]_D^{25}$ 128° in Et_2O . Sapon. of (B) gave *akundarol* (D), $\text{C}_{18}\text{H}_{34}\text{O}_2$, needles, m. 215° (*acetate*, needles, m. 222°), oxidized by CrO_3 in HOAc to *akundaric acid*, isolated as the *silver salt*, $\text{C}_{18}\text{H}_{32}\text{O}_2\text{Ag}$, faintly green, amorphous. Sapon. of (C) gave *mudarol* (E), $\text{C}_{26}\text{H}_{48}\text{O}_2$, hexagonal plates, m. 176° (*acetate*, needles, m. $195-6^\circ$), oxidized to *mudaric acid*, amorphous, m. 225° , purified through the *silver salt*, $\text{C}_{26}\text{H}_{46}\text{O}_2\text{Ag}$, faintly green, amorphous. (B), (C), and their alcs. gave color reactions very similar to those of cholesterol and phytosterol. A little (D), in 2 cc. CHCl_3 , treated with 20 drops Ac_2O and 1 drop H_2SO_4 , gave the usual violet-pink color, while (E) gave an intense blue. The resinous material evolved NH_3 and amines when boiled with concd. aq. KOH , and was finally purified to a hard, brittle mass of the comp. $\text{C}_{24}\text{H}_{47}\text{O}_{12}\text{N}$. M. HEIDELBERGER.

Condensation of aromatic hydroxyaldehydes with diketohydrindene. SOSALE G. SASTRY AND BROJENDRA N. GHOSH. London. *J. Chem. Soc.* 107, 1442-9(1915).—An attempt to obtain compds. structurally similar to the substances derived from brazilin, hematoxylin, and analogous compds. No definite products could be isolated from the action of PhNHNH_2 on 2'-hydroxy-1,3-diketo-2-benzylidenehydrindene (A) (Kostanecki and Saczkowski, *Ber.* 30, 2139(1897)); the *dibromo derivative* forms pale yellow needles, m. 122° . When HCl was passed through a soln. of 3 g. *o*- $\text{HOC}_6\text{H}_4\text{CHO}$ and 3.5 g. $\text{C}_6\text{H}_4(\text{CO})_2\text{CH}_3$ in MeOH 4'-keto-2,3-indeno-1,4-benzopyranol anhydrohydrochloride (I) sepd., orange-red crystals with 1 H_2O , brown when anhydrous, chars above 320° . The α -quinonoid bonds are assigned the positions given in (I), rather than as

formulated in similar substances by Perkin, Robinson, and Turner (*C. A.* 2, 2781). (I) may also be prepd. by passing HCl through (A) in MeOH. In alc., with aq. NaOAc, it gives *4'-keto-2,3-indeno-1,4-benzopyranol* (II), $C_{18}H_{10}O_4 \cdot 0.5H_2O$, brown needles, chars on heating. Heated with 10% aq. NaOH, (I) yields (A), identified as the Ac deriv. 2 g. 2,4-(HO) $_2$ C $_6$ H $_4$ CHO and 2 g. C $_6$ H $_4$ (CO) $_2$ CH $_3$ in alc., heated 0.5 hr. with 3 g. KOH in 5 cc. H $_2$ O, gave *2',4'-dihydroxy-1,3-diketo-2-benzylidenehydrindene*, brown prisms, chars at high temps., sol. in NaOH with a red color, gives a brown ferric salt; the *acetyl derivative*, $C_{20}H_{14}O_4 \cdot 0.5H_2O$, brown prisms, changing color at 210° and m. 235° (decompn.); with 2 atoms Br in HOAc, yields a *dibromo derivative*, brownish needles, does not m. 320°. The corresponding *7-hydroxy-4'-keto-2,3-indeno-1,4-benzopyranol anhydrohydrochloride* was prepd. as was (I), red prisms, sol. in alkalis with a red-violet color; *7-hydroxy-4'-keto-2,3-indeno-1,4-benzopyranol*, dark brown, amorphous ppt. with a metallic luster. *2'-Hydroxy-1,3-diketo-2-naphthylidenehydrindene*, using 2-HOC $_6$ H $_4$ CHO, dark red plates, m. 298° (decompn.); the dull brown alc. soln. turns red on adding FeCl $_3$. Yield, poor. *4'-Keto-2,3-indeno-1,4-naphthopyranol anhydrohydrochloride*, dark brown prisms, shrinks 110°, decomps. above 130°; *4'-keto-2,3-indeno-1,4-naphthopyranol*, brown prisms, m. 125° (decompn.). M. H.

Behavior of nitriles towards organometallic derivatives of magnesium. EUSTACE E. TURNER. Univ. London. *J. Chem. Soc.* 107, 1459-64(1915).—de Bruyn's method (*Rec. trav. chim.* 2, 210(1883)) for the prepn. of 2,6-(EtO) $_2$ C $_6$ H $_3$ CN was improved by air-drying the black ppt. obtained on adding HCN soln. to an alc. soln. of *m*-C $_6$ H $_4$ (NO $_2$) $_2$ and extg. with Et $_2$ O in a Soxhlet. The nitrile was recovered unchanged in all expts. with RMgX, even when using high-boiling solvents. The effect of steric hindrance is thus very marked. In the prepn. of *p*-MeC $_6$ H $_4$ COCH $_2$ Ph(A) by the action of MeC $_6$ H $_4$ MgI on PhCH $_2$ CN the poor yield is ascribed to the weakening of the nitrile properties by the acidic CH $_2$ group. (A) is best prepd. from MeC $_6$ H $_4$ CN and PhCH $_2$ MgCl in Et $_2$ O; when C $_6$ H $_6$ is used as the solvent an oil is formed, which, dissolved in hot alc. and cooled, yields *p*-tolyl α,β -diphenylethyl ketone (B), MeC $_6$ H $_4$ COCHPhCH $_2$ Ph, needles, m. 90°, is not affected by ketone reagents, Br-H $_2$ O, KMnO $_4$ in acid or alk. soln., or concd. HCl at 160° for 4 hrs. Other products of the reaction were (PhCH $_2$) $_2$, a little (A), and small amts. of unidentified substances. (B) was synthesized from (A) and PhCH $_2$ Cl with Na in alc. Equal wts. of (A) in alc. and H $_2$ NCONHNH $_2$ ·HCl in a little H $_2$ O at 180° for 3 hrs. in a sealed tube gave a substance, C $_{21}$ H $_{22}$ N $_2$, yellow needles, m. 181°, yielding the ketone on hydrolysis. The absence of the CONH $_2$ group is indicated by the analysis and by the fact that no NH $_3$ is evolved on heating with KOH; Br in CHCl $_3$ has no action. M. HEIDELBERGER.

Conversion of the natural flavone coloring matters into pyranol dyes. EDWIN R. WARSON, KUMUD B. SEN AND VISHNU RAM MEDHI. Dacca. *J. Chem. Soc.* 107, 1477-89(1915); cf. *C. A.* 8, 1748.—In the previous paper the name "benzopyran" should be changed to "benzopyranol." The work therein reported is continued along the same lines. 3,5,7-Triethoxy-2-*m,p*-diethoxyphenyl-4-ethylbenzopyranol, from the anhydrohydriodide (A) in alc. and concd. aq. NH $_3$, followed by extn. with Et $_2$ O, colorless, viscous oil; *anhydrohydrochloride*, crimson; *chloroplatinate*, red needles with 2 H $_2$ O, m. 197°. (A) and AlCl $_3$ at 160° for 1 hr. give 3,5,7-trihydroxy-2-*m,p*-dihydroxyphenyl-4-ethyl-1,4-benzopyranol *anhydrohydrochloride triethyl ether*, C $_{18}$ H $_{16}O_7$ (OEt) $_3$ (OH) $_2$ EtCl·H $_2$ O, almost black powder, sol. in dil. HCl with a crimson color; the free base is violet and dyes alum-mordanted wool a fast blue shade; the same compd. is apparently formed by treating (A) with 33% H $_2$ SO $_4$ at 140°. If the reaction mass formed in the AlCl $_3$ expt. is extd. with dil. HCl and H $_2$ PtCl $_6$ added, there is formed in small amt. the *chloroplatinate* of 3,5,7-trihydroxy-2-*m,p*-dihydroxyphenyl-4-ethyl-1,4-benzopyranol *anhydrohydrochloride tetraethyl ether*, scarlet prisms with 1 H $_2$ O, m. 170-5°. Quercetin

tri-Me ether (B) and 5 mols. EtMgI gave unchanged (B) and 3,5,7-trihydroxy-2-m,p-dihydroxyphenyl-4-ethyl-1,4-benzopyranol anhydrohydriodide trimethyl ether, red needles m. 163-5°, dyes only terra-cotta shades, showing that the ether groups are in different positions from those in the tri-Et ether. 3,5,7-Triethoxy-4-phenyl-2-m,p-diethoxyphenyl-1,4-benzopyranol anhydrohydrochloride was obtained from quercetin penta-Et ether (C) and PhMgBr, forming red needles which were not freed completely from (C); boiled with HI (d. 1.7), it yields impure 3,5,7-trihydroxy-4-phenyl-2-m,p-dihydroxyphenyl-1,4-benzopyranol anhydrohydriodide, dark red prisms; the free base is violet, amorphous, and unstable, and dyes the same shades as quercetin. 3,5,7-Triethoxy-4-methoxyphenyl-2-m,p-diethoxyphenyl-1,4-benzopyranol anhydrohydrochloride, crimson crystals with 1 H₂O (chloroferrate, red needles, m. 190°); de-ethylated with concd. HCl at 150-80°, opening the tube after 6 hrs., resealing, and again heating 6 hrs., it forms a substance C₂₄H₂₂O₆Cl (I or II), dark red needles with a blue reflex, gives a green

(I)

(II)

color with KOH and dyes alum-mordanted wool a fast greenish blue; an Ac deriv. could not be prepd. Using morin penta-Et ether (colorless, m. 112-4°; cf. Perkin, C.A. 7, 2932) no cryst. derivs. could be prepd., but with the penta-Me ether and MeMgI, 3,5,7-trimethoxy-2-o,p-dimethoxyphenyl-4-methyl-1,4-benzopyranol anhydrohydriodide was obtained, yellow needles; the corresponding pentahydroxy derivative was prepd. by de-methylation with HI. Luteolin tetra-Et ether and EtMgI gave 5,7-diethoxy-2-m,p-diethoxyphenyl-4-ethyl-1,4-benzopyranol anhydrohydriodide, orange needles, m. 169-72°; the free base forms colorless needles, m. 116-7°; de-ethylation of the salt with HI yields 5,7-dihydroxy-2-m,p-dihydroxyphenyl-4-ethyl-1,4-benzopyranol anhydrohydriodide, gives a violet color with KOH and dyes alum-mordanted wool a mauve color. It is the fastest of the series. Apigenin trimethyl ether and EtMgI gave 5,7-diethoxy-2-p-ethoxyphenyl-4-ethyl-1,4-benzopyranol anhydrohydriodide, orange rhombs, m. 178-80°; chloroplatinate, red, amorphous, contains 2 H₂O; de-ethylated with HI it gives the corresponding hydroxy compound, needles, gives a crimson color with KOH and dyes alum-mordanted wool a brown-orange color. A table is given of the dyeing properties of the HO compds. and the absorption spectra of all are given. The multiplication of auxochromes moves the front of the band towards the red end of the spectrum. The curves of the salts of the ethers differ very little from those of the corresponding HO compds.

M. HEIDELBERGER.

Preparation of ethyl bromide. FRANK E. WESTON. London. *J. Chem. Soc.* 107, 1489-90 (1915).—The disadvantages of the present lab. methods of prepn. are discussed. The following method gives rise to no Et₂O and gives yields of 80-90% of EtBr, based on either the alc. or NaBr. Mol. amts. of abs. alc., H₂SO₄ (d. 1.84) 15% more used than the theory), and NaBr are used. The alc. is mixed with 5-10% of its wt. of H₂O and the H₂SO₄ added, with cooling. The NaBr, coarsely powdered, is then added, and the whole slowly heated on a H₂O bath, using a condenser whose outlet dips into cooled H₂O. The temp. is raised only as the formation of EtBr slackens;

above 100° a sand bath is substituted for the H₂O bath. Any HBr formed may be recovered from the H₂O in the receiver.
M. HEIDELBERGER.

Action of diazomethane on some aromatic acyl chlorides. DOUGLAS A. CLIBBENS AND MAXIMILIAN NIERENSTEIN. Univ. Bristol. *J. Chem. Soc.* 107, 1491-4 (1915).—An extension of the observations of Schlotterbeck (*C. A.* 1, 1266) and Hans Meyer (*C. A.* 1, 1410), who found that aldehydes, treated with CH₃N₂, yielded Me ketones. With ARTHUR GRAKE it was found that Ph₃COH, Ph₂CHOH, PhCH₂OH, and Bz-CH₂OH were unaffected by CH₃N₂; benzoic and mandelic acids, however, gave the Me esters. In the expts. described below, the acid chlorides were dissolved in dry Et₂O and treated with an Et₂O soln. of CH₃N₂ prepd. according to Standinger and Kupfer (*C. A.* 6, 1297). The Et₂O was removed and the residue fractionated *in vacuo*. A small amt. of a nitrogenous by-product was generally obtained as the last fraction. BzCl gave BzCH₂Cl (72% of the theory), while BzBr yielded BzCH₂Br (yield, 28%). PhCH₂COCl gave *benzyl chloromethyl ketone*, needles, m. 72-3° (yield, 84%), while PhCH₂CH₂COCl yielded *β-phenylethyl chloromethyl ketone*, needles, m. 84-5°; yield, 82%. *p*-MeOC₆H₄COCH₂Cl was formed in 86% yield. *o*-AcOC₆H₄COCl (Anschütz, *C. A.* 3, 2976) gave coumaranone in 92% yield, AcCl being eliminated. 2,4-(HO)₂C₆H₃-CO₂H was obtained in 92-5% yield by passing CO₂ through a hot soln. of *m*-C₆H₄(OH)₂ in aq. NaHCO₃ or KHCO₃. 2,4-AcO(MeO)₂C₆H₃CO₂H, m. 145-7°, not 140°. 2-Acetoxy-4-methoxybenzoyl chloride, from the acid and PCl₅, needles, m. 81-2°; 3-methoxycoumaranone, yield, 88%. 3,4,5-(MeO)₃C₆H₂COCl gave a nitrogenous product of high m. p.
M. HEIDELBERGER.

Studies in ring formation. I. The Kautler formula for derivatives of diphenyl. EUSTACE E. TURNER. Univ. London. *J. Chem. Soc.* 107, 1495-1500 (1915).—From the fact that 4,4-dihalodiphenyls do not react with Na as do the 2,2'-comps., K. concludes that these positions are spatially remote. With an excess of benzidine, AcCH₂Ac forms *diacetylisopropylidenebenzidine* (A), (C₆H₄N)₂CMech:CMech(OH)₂, pale yellow or brown crystals, m. 198°; with Br in CHCl₃ it gives a *tetrabromo derivative*, needles. (A), warmed with H₂SO₄ for 1 hr., gives 2,4,2',4'-tetramethyl-6,6'-diquinoyl. In boiling C₆H₁₀, (C₆H₄NH₂)₂ and AcCH₂Ac yield, if the ketone in C₆H₁₀ is added drop by drop during 1 hr., *monoacetylisopropylidenebenzidine*, H₂N-C₆H₄-C₆H₄-N:—CMech₂Ac, pale yellow crystals, m. 137°; a pure chloroplatinate could not be prepd.; condensation of the free CO group with the remaining NH₂ group could not be effected, although this possibility is indicated by Kautler's formula. For positive evidence as to K.'s formula, see Cain, *et al.*, *C. A.* 8, 3416.
M. HEIDELBERGER.

Composition, structure and properties of gynocardic acid and some of its derivatives. I. I. I. OSTROMUTSLENSKII AND A. M. BERGMANN. *J. Russ. Phys. Chem. Soc.* 47, 313-34 (1915).—Pure gynocardic acid, C₁₇H₃₃CO₂H (a), constitutes the largest portion of the com. product sold under this name. The impurities consist largely of isomers of (a). The pure acid may be obtained either by means of its Cu salt or by prolonged fractional recrystn. from alc.; colorless leaflets of a slight odor of coconut oil, m. 67.5-5.5°, readily sol. in most org. solvents; its combustion presented unusual difficulties, only Denstedt's method giving satisfactory results; it contains a double union, is isomeric with oleic and elaidic acids, and resembles them in many of its properties. The fact that it possesses specific therapeutic properties (in tuberculosis and leprosy) makes it worth while to look for other unsatd. acids of the aliphatic series which may turn out to have special medicinal value. The alkali salts of (a) are soaps little sol. in H₂O, the NH₄ salt is quite sol. in dil. alc. The Ba salt is colloidal and insol. in all solvents tried except aromatic hydrocarbons. From its C₆H₆ soln. the Ba salt seps. out on standing as an opaque amorphous mass almost as solid as a rock. Copper gynocardate, (C₁₇H₃₃CO₂)₂Cu, was obtained in 2 modifications designated as α and β.

The α -compd. is the direct product of interaction of (a) with $(\text{AcO})_2\text{Cu}$, has a green color and is insol. in H_2O , but sol. in fats and most org. solvents. On standing even *in vacuo* or by warming its soln. it gradually though incompletely changes to the β -modification which is insol. in all solvents tried. The α -salt readily unites with $(\text{AcO})_2\text{Cu}$ to form an insol. double salt $((\text{AcO})_2\text{Cu})_m \cdot [(\text{C}_{17}\text{H}_{33}\text{CO}_2)_2\text{Cu}]_n$, and with itself to form an insol. double salt or polymer $[(\text{C}_{17}\text{H}_{33}\text{CO}_2)_2\text{Cu}]_n$. The β -salt is doubtless such a polymer. With CaCl_2 , BaCl_2 or ZnCl_2 the α -salt also forms double salts. The α -salt m. $69.5-70.5^\circ$, the β -salt has a considerably higher m. p. The direct reconversion of the β - into the α -salt was not possible, but by liberating (a) from the former with 10% H_2SO_4 and treating it with $(\text{AcO})_2\text{Cu}$ the α -salt results. A satd. soln. of the α -salt in turpentine at 50° gelatinizes on cooling and assumes a dark green color. In fats or aliphatic acids the α -salt gives supersatd. solns. which keep for several days. On heating a soln. of the α -salt the green color changes to brown, but on cooling the original color gradually returns. *Methyl gynocardate*, $\text{C}_{17}\text{H}_{33}\text{CO}_2\text{Me}$, fluorescent oil of an agreeable odor, b. $320-30^\circ$, sol. in concd. H_2SO_4 , but the soln. gradually darkens, and upon diln. with H_2O develops a yellowish green fluorescence. *Hydroxygynocardic acid* (not analyzed), from (a) and H_2SO_4 , prisms of a stearic acid odor, gives a sol. *potassium salt*. The *dibromide*, $\text{C}_{17}\text{H}_{33}\text{Br}_2\text{CO}_2\text{H}$, by the action of Br on (a) in AcOH , heavy oil, crystg. at low temps., not volatile with steam, and decomp. when heated *in vacuo* at 100° .

H. M. GORDIN.

Saturated bicyclic hydrocarbons. S. S. NAMEŤKIN. *J. Russ. Phys. Chem. Soc.* 47, 405-9 (1915).—General remarks by N. on his work with collaborators on camphane, isocamphane and camphenylane (following 3 abstrs.), bringing out the following points: The nitration of these substances with dil. HNO_3 (Konovalov's method) gives secondary NO_2 compds. only, though they all contain also tertiary C atoms. While in the nitration of paraffins the NO_2 goes to a particular C, in the above bicyclic compds. it goes in the direction of both cycles, giving where possible (camphenylane) 2 isomeric NO_2 compds. The above hydrocarbons also have a tendency to form stereoisomeric NO_2 derivs. having different phys. properties. Owing to the ready interaction of HNO_3 with ketones, nitration as a rule gives only traces of the latter; since, however, the ketones of bicyclic hydrocarbons do not readily interact with HNO_3 , the nitration products of the above hydrocarbons contained considerable amts. of ketones. The latter are identical with the ketones obtained by oxidizing the NO_2 compds. with alk. KMnO_4 . Similarly the dibasic acids found in the nitration products are identical with the acids obtained by oxidizing these ketones.

H. M. GORDIN.

Action of nitric acid on camphane. S. S. NAMEŤKIN, M. K. DOBROVOL'SKAYA AND M. P. OPARINA. *J. Russ. Phys. Chem. Soc.* 47, 409-13 (1915); cf. preceding abstr. —The work of Konovalov and Kikina on the nitration of camphane (erroneously called by them anhydrocamphene) with dil. HNO_3 (*J. Russ. Phys. Chem. Soc.* 34, 935 (1902)) was repeated with purer material obtained by Kizhner's method (*C. A.* 6, 347). The results were as follows: The product consisted of *dl*-camphoric acid and

2 stereoisomeric α - and α' -nitrocamphanes,

$$\begin{array}{c} \text{CH}_2-\text{CH}-\text{CH}_2 \\ | \quad | \quad | \\ | \quad \text{CMe}_2 \quad | \\ | \quad | \quad | \\ \text{CH}_2-\text{CMe}-\text{CHNO}_2 \end{array}$$

The 1st m. $128-30^\circ$, and is identical with K. and K.'s compd., the 2nd m. $140-5^\circ$, and is identical with Forster's compd. (*J. Chem. Soc.* 77, 257). Upon oxidation both gave *dl*- α -camphor, which gave a *semicarbazone* m. $232-3^\circ$.

H. M. GORDIN.

Isocamphane. S. S. NAMEŤKIN AND L. N. ABAKUMOVSKAYA. *J. Russ. Phys. Chem. Soc.* 47, 414-24 (1915); cf. preceding abstrs.—When isocamphane (I) is treated

Chemical Abstracts.

1 dil. HNO_3 the product consists of ω -nitrocamphene (II) and what are probably stereoisomeric β - and β' -nitroisocamphanes (III), which could not be sep'd. from each other. Their mixt. m. $48-9^\circ$, and gave upon oxidation 2 stereoisomeric β - and β' -isocamphors (IV). The 1st m. $91-2^\circ$ (semicarbazone, m. $196-8^\circ$), the 2nd m. $63-4^\circ$

(semicarbazone, m. 195°). Further oxidation of both ketones gave the same *d*-isocamphoric acid (V), probably a mixt. of *cis-trans*-isomers, begins to cake 176° , m. $178-80^\circ$, in most respects resembles its isomer, camphoric acid.

H. M. GORDIN.

H. M. KHUKHRIKOVA.

Camphenylene and its derivatives. S. S. NAMETKIN AND A. M. KHUKHRIKOVA. J. Russ. Phys. Chem. Soc. 47, 425-34(1915); cf. preceding abstrs.—Camphenylene (I)

was prepd. by Kizhner's method from camphenylene (II). The latter was converted into the hydrazones $\text{C}_8\text{H}_{11}\text{NNH}_2$, m. $29-31^\circ$, and this into the azine $(\text{C}_8\text{H}_{11}\text{N})_2$, m. 148.5° . (I) m. 156° , b_{714} 142.5° , d_4^{20} 0.8547 , n_D^{20} 1.4555 , b_D $124-5^\circ$, d_4^{20} 1.077 , n_D 1.4835 , HNO_3 gave β -nitrocamphenylene (a), m. $18-20^\circ$, b_{714} $124-5^\circ$; semicarbazone, m. $192-3^\circ$. Further oxidation of (III) gave apofenchonecamphoric acid (IV), m. $145.5-5^\circ$. Reduction of (a) gave the corresponding β -camphenylamine, $\text{C}_8\text{H}_{11}\text{NH}_2$, m. $10-4^\circ$, b_{714} $189-9.5^\circ$, d_4^{20} 0.9278 , n_D 1.4822 ; benzoyl compound, $\text{C}_8\text{H}_{11}\text{NHBz}$, could not be obtained pure, probably on account of formation of stereoisomers.

H. M. GORDIN.

Diaminofluorenes. HERMANN RUDOLPH. Ztg. 30, 293-5(1915).—Of the possible sym. diamines of fluorene, only the 2,7-deriv., i. e., corresponding to benzidine, is known (cf. Schultz, Ann. 203, 101; Diels, Schill and Tolson, Ber. 35, 3284). Attempts to prep. the as yet unknown 3,6-diaminofluorene were unsuccessful. On reducing the products obtained by nitrating fluorene itself, several NH_2 derivs. resulted, from which a diaminofluorene, needles, m. 156° (acetyl compound, m. 269°), was isolated. W. O. E.

Some derivatives of urea. M. SCHOLTZ. Univ. Greifswald. Arch. Pharm. 253, 111-7(1915).—Continued heating of urea with BzMe and CHCl_3 . Attempts to prep. *diacetophenone urea*, $\text{CO}(\text{N}:\text{CMePh})_2$, AcOH and CHCl_3 . Similar treatment of BzEt leads to the formation of *dipropiophenone urea*, $\text{CON}(\text{CMePh})_2$, rods from alc. m. $196-7^\circ$. In the case of BzPh , a biuret deriv. results: *benzophenone biuret*, $\text{Ph}_2\text{C}:\text{NCONHCONH}_2$.

needles from alc. remaining solid at 300° but decomp. at higher temp. In this reaction the greater part of the urea is converted into cyanuric acid while much of the BzPh. remains unchanged. In the interaction of urea and $\text{AcCH}_2\text{CO}_2\text{Et}$, Behrend (cf. *Ann.* 229, 5) obtained the equimol. condensation product, the Et uramidocrotonate. On heating the above substances, however, at 170° , they react in the proportion of 3 mols. urea and 1 mol. $\text{AcCH}_2\text{CO}_2\text{Et}$ with the formation of the β -diureidobutyric ureide, $\text{MeC}(\text{NHCONH}_2)_2\text{CH}_2\text{CONHCONH}_2$, flakes from Et_2O , cryst. powder from alc., m. at no definite temp. At 200° , this substance loses NH_3 , thereby yielding the compd., 1,3-diketohexahydrokynidino-5-methyl-5-acetic ureide, $\text{NH}(\text{CONH})_2\text{CMeCH}_2\text{CONHCONH}_2$, cryst. powder softening at 170° , decomp. 200° . The corresponding compds. of urea with $\text{BzCH}_2\text{CO}_2\text{Et}$ are: β -phenyl- β -diureidopropionic ureide, $\text{PhC}(\text{NHCONH}_2)_2\text{CH}_2\text{CONHCONH}_2$, rods beginning to decomp. 195° but m. suddenly 213° ; 1,3-diketohexahydrokynidino-5-phenyl-5-acetic ureide, $\text{NH}(\text{CONH})_2\text{CPhCH}_2\text{CONHCONH}_2$.

W. O. R.

p-Anisidide and *p*-phenetidide of thioglycolic acid. H. BECKURTS AND G. FREUCHS. Tech. Hochschule Braunschweig. *Arch. Pharm.* 253, 136-55 (1915).—The anilide of carbaminothioglycolic acid is converted by NH_3 into that of thioglycolic acid, $\text{HSCH}_2\text{CONHPh}$, and CONH . This compd. is by virtue of its SH group capable of yielding a great variety of derivs., notably by substituting H of the SH group for alkyl and other groups. [In the following, $\text{R} = \text{CH}_2\text{CONHC}_6\text{H}_4\text{OMe}$.] On heating an alc. soln. of RCl with KCNS , carbaminothioglycolic *p*-anisidide resulted, NH_2COSR , needles, m. $160-1^{\circ}$, which with NH_3 yielded thioglycolic *p*-anisidide, RSH , needles, m. 116° . The latter is converted by FeCl_3 into dithioglycolic *p*-anisidide, $(-\text{SR})_2$, needles, m. 185° . Other *p*-anisidides prepd. were: methylthioglycolic MeSR , needles, m. 94° ; ethylthioglycolic, needles, m. 68° ; isopropylthioglycolic, needles, m. 58° ; isobutylthioglycolic, leaflets, m. 86° ; benzylthioglycolic, needles, m. 82° ; ethylenethioglycolic $(\text{CH}_2\text{SR})_2$, microscopic needles, m. $177-8^{\circ}$; propylenethioglycolic $\text{C}_3\text{H}_6(\text{SR})_2$, cryst. flour, m. 103° ; trimethylenethioglycolic, $\text{CH}_2(\text{CH}_2\text{SR})_3$, leaflets, m. 139° ; dimethylmethylenethioglycolic, $\text{Me}_2\text{C}(\text{SR})_2$, needles, m. 168° ; hydroxyethylthioglycolic, $\text{HOCH}_2\text{CH}_2\text{SR}$, leaflets, m. 78° ; carbethoxythioglycolic, EtO_2CSR , needles, m. 90° ; thiodiglycolic amide, $\text{H}_2\text{NCOCH}_2\text{SR}$, needles, m. 148° ; thioglycol- α -lactic acid $(\text{MeCO}_2\text{H})\text{CHSR}$, needles, m. 121° . Similarly, the *p*-phenetidides of carbaminothioglycolic acid, $\text{H}_2\text{NCOSCH}_2\text{CONHC}_6\text{H}_4\text{OEt}$, leaflets, m. 123° , and thioglycolic acid, leaflets, m. 117° , were prepd., the latter yielding the following *p*-phenetidides: dithioglycolic, needles, m. 186° ; methylthioglycolic, needles, m. 63° ; ethylthioglycolic, leaflets, m. 87° ; isopropylthioglycolic, needles, m. $99-100^{\circ}$; isobutylthioglycolic, crystals, m. $106-7^{\circ}$; benzylthioglycolic, needles, m. 111° ; ethylenethioglycolic, needles, m. 197° ; propylenethioglycolic, needles, m. 158° ; trimethylenethioglycolic, needles, m. 147° ; dimethylmethylenethioglycolic, needles, m. 171° ; allylthioglycolic, asbestos-like needles, m. 78° ; hydroxyethylthioglycolic, leaflets, m. 81° ; carbomethoxythioglycolic, needles, m. 119° ; carbethoxythioglycolic, needles, m. 106° ; thiodiglycolic, needles, m. 114° ; barium salt, $(\text{C}_{12}\text{H}_{14}\text{NSO}_4)_2\text{Ba}$, cryst.; thioglycol- α -lactic, needles, m. 113° ; thiodiglycolic amide, needles, m. 155° ; thiodiglycolic ethyl ester, $\text{EtCO}_2\text{CH}_2\text{SCH}_2\text{CONHC}_6\text{H}_4\text{OEt}$, oil, gradually becoming cryst. W. O. R.

The action of chlorine on quinine. A. CHRISTENSEN. *Ber. pharm. Ges.* 25, 256-81 (1915).—Cl in excess easily effects soln. of the alkaloid. If, however, the Cl is applied in limited amt., several distinct products are formed, according as 2, 4 or 6 atoms of Cl are used. Cl_2 per quinine mol.—Quinine dichloride, $\text{C}_{20}\text{H}_{24}\text{Cl}_2\text{N}_2\text{O}_2$, amorphous powder, m. 97° , insol. in H_2O , easily sol. in CHCl_3 and alc., difficultly sol. in Et_2O , gives the thalleioquin reaction; hydrochloride, $\text{C}_{20}\text{H}_{24}\text{Cl}_2\text{N}_2\text{O}_2 \cdot 2\text{HCl} \cdot 2\text{H}_2\text{O}$, cryst., $\alpha_D 169.3^{\circ}$ (0.6905 g. in 25 cc.), yields with alc. KOH dehydroquinine, $\text{C}_{20}\text{H}_{22}\text{N}_2\text{O}_2$, m. 181° (oxalate, m. $133-4^{\circ}$); nitrate, $\text{C}_{20}\text{H}_{24}\text{Cl}_2\text{N}_2\text{O}_2 \cdot 2\text{HNO}_3$, prisms from alc. or H_2O ;

hydrobromoperbromide, $C_{20}H_{24}Cl_6N_2O_7 \cdot 2HBr \cdot Br_2$, orange-red cryst. powder; *herapathite*, $4C_{20}H_{24}Cl_6N_2O_7 \cdot 3H_2SO_4 \cdot 2HI \cdot I_2$, cantharidin-green crystals; *quinine hydroxychloride*, $C_{20}H_{24}Cl(OH)N_2O_7$, α_D 131.35° (4.6435 g. in 25 cc.). Quinine dichloride and Cl_2 yield in mol. proportions a product from which a *nitrate* of the *tetrachloride* was prepd., $C_{19}H_{20}Cl_4N_2O_7 \cdot HNO_3$, colorless crystals. $2Cl_2$ per quinine mol.—*Hydrochlorides* "A" and "B," $C_{19}H_{22}Cl_3N_2O_7 \cdot 2HCl \cdot 2\frac{1}{2}H_2O$ and $C_{19}H_{22}Cl_3N_2O_7 \cdot 2HCl$; *nitrate*, $C_{19}H_{22}Cl_3N_2O_7 \cdot HNO_3 \cdot 3H_2O$, long needles yielding on oxidation β, γ -pyridinedicarboxylic acid; *hydriodide*, $C_{19}H_{22}Cl_3N_2O_7 \cdot HI \cdot 4H_2O$; *5-chloro-6-hydroxycinchonine hydroxychloride*, $C_{19}H_{22}Cl_3N_2O_7 \cdot 4H_2O$, from both "A" and "B," long needles, m. 172–3°. This alkaloid contains 3 OH groups. Corresponding thereto, *5-chloro-6-hydroxycinchonine*, $C_{19}H_{22}Cl_3N_2O_7 \cdot 4H_2O$, was prepd. from hydrochloroquinine, $C_{19}H_{22}ClN_2O_7$ (cf. Comstock and Koenig, *Ber.* 20, 2517) as long prisms, m. 174–5°; *hydrochloride*, $C_{19}H_{22}Cl_3N_2O_7 \cdot 2HCl \cdot 3H_2O$.—Quinine hydrochloride with 3 Cl_2 , or better hydrochloroquinine with 2 Cl_2 per mol., yields *5-dichloro-6-ketocinchonine hydrochloride nitrate*, $C_{19}H_{21}Cl_5N_2O_7 \cdot HNO_3$, small quadratic plates. W. O. E.

Hexabromodiacyetyl. C. LORING JACKSON AND ROGER ADAMS. *J. Am. Chem. Soc.* 37, 2522–36(1915); cf. *C. A.* 8, 2872.— $CBR_2CHBrCOCOCBr_2$ and its principal derivs. must be struck from the list of known compds., for the yellow ketone obtained by the action of Br and H_2O on the 2 acids formed by the treatment of tetrabromo-*o*-quinone with NaOH and to which the above structure was assigned has now been found to be *hexabromodiacyetyl* (a), $(COCBr_2)_2$. It is now prepd. by adding to 200 g. NaOH in 1 l. H_2O at a few degrees above zero 100 g. of tetrabromo-*o*-quinone in small portions with const. shaking, allowing to stand 2–3 hrs. in ice, then 5 hrs. at room temp., pouring into 400 cc. of concd. HCl slowly and with const. stirring, filtering after allowing to settle 5–10 min., adding Br in 2 cc. portions with shaking after each addition until the liquid remains reddish (23–3 cc. in all if the quinone used was pure), filtering the ppt. after 5–10 min., drying on clay, powdering, extg. with successive portions of petr. ether (b. 30–50°) until only a brown tarry impurity is left, concg. and cooling, whereupon the (a) seps. in orange-yellow, arrowhead-shaped plates, m. 100–1° (yield, 21–4 g.), unattacked by strong acids in the cold or on short heating at 100°, sol. without change in appearance but with loss of 1–2% Br in boiling fuming HNO_3 , while several hrs. boiling seems to decomp. it entirely; boiling H_2SO_4 dild. with its vol. of H_2O gives a little $CHBr_3$; H_2O , H_2O_2 or const. boiling HBr do not effect it in the cold but at 100° in sealed tubes CBR_2COCH_2Br and $CHBr_3$ are formed. Attempts to prep. a dicyanohydrin by heating with aq. 40% HCN at 40° gave a yellow oil which on hydrolysis with HCl at 100° again gave only an oil. Alk. reagents (NaOH, KOH, Ba(OH) $_2$, Na_2CO_3) easily decomp. (a) into 2 mols. $CHBr_3$ and 1 mol. of an oxalate; the same is true of hot NaOMe but in the cold a product m. about 80° is formed. Boiling aq. NaOAc gives $CHBr_3$, HBr and $(CO_2H)_2$; $CaCO_3$ in boiling H_2O gives tarry products and evolves a sharp odor like that of a bromoketone; Ag and boiling H_2O produce the same odor but give AgBr and $(CO_2H)_2$; aq. NH_3 and alc. in the cold yield $(CONH_2)_2$ and $PhNH_2$ in C_6H_6 gives $(CONHPh)_2$; *o*- $C_6H_4(NH_2)_2$ gives *o*-phenyleneoxamide; $NH_2OH \cdot HCl$ apparently does not react; $PhNHNH_2$ removes Br; C_6H_5N forms a black tar; $AcCl$, Ac_2O , $BzCl$, aq. H_2SO_4 have no action; Zn and AcOH or Al-Hg give tars; Br does not react in the cold and forms tars on heating in sealed tubes. Allowed to stand 4–5 days in MeOH (not abs.) it gives 0.5 its wt. of *hexabromodiacyetyl monomethyl-hemiacetal* (b), $CBR_2COC(OH)(OMe)CBR_2$, m. 105°; it seps. from petr. ether in 3 kinds of crystals: (1) on cooling or rapid evapn. mostly in long slender prisms, sometimes with a bluntly pointed, sometimes with a square end, turning opaque, without losing wt., in air; (2) on slow evapn. chiefly in short, square-ended prisms usually bevelled on the edges and sometimes on the ends; (3) in octahedra modified by many small planes. (1) and

(2) usually cryst. together and are orthorhombic or perhaps monoclinic, while (3), which were obtained only once under conditions which could not be established, seemed to be tetragonal and have a much more brilliant luster than the others; on recrystn. from MeOH they give (1). The MeOH soln. of (b) turns yellow in a few min. and although colorless crystals sep. from it they melt lower ($100-1^{\circ}$) while in contact with abs. MeOH for some weeks (b) changes to a red oil. That this is due to the formation of a dihemiacetal is rendered improbable by the facts that the C_6H_5 soln. also turns yellow in the air and evapn. of the C_6H_5 leaves a brownish residue, and crystals of (b) have a tendency to turn brown in the air, especially if it is moist. On the other hand, concd. HNO_3 dissolves (b) without change; H_2SO_4 (1:1) does not decomp. it until boiled some time, when it gives an oil smelling of camphor. (b) distils slightly with steam, is unstable towards alkalis, alc. NH_3 giving NH_4Br and $PhNH_2$ an oil; $NH_4OH.HCl$, Ac_2O and $AcCl$ have no action; boiling with Ag in MeOH yields an oil and crystals m. about 70° . *Monoethylhemiacetal* (c), narrow plates from petr. ether, m. $96-7^{\circ}$, easily turns brown in moist air, the Br content decreasing about 2%; heated in sealed tubes with H_2O at 100° for several days it gives CO_2 , $CHBr_3$, HBr and probably HO_2CCO_2Et ; attempts to reconvert it into (a) by evapg. with dil. H_2SO_4 until the b. p. rose from 110° to 135° gave only unchanged (a); after several hrs. at 150° with strong H_2SO_4 , there is decompn. but no formation of (a); 3 hrs. boiling with const. boiling HBr or heating to 100° in sealed tubes produces no change. With other reagents it behaves like (b). In the prepn. of (a), if the filtrate from it is allowed to stand with 5 cc. Br a red oil is formed which becomes semicryst. on standing and gives a mixt. of (a) and $CBBr_3COCH_2Br$ on crystn. from petr. ether. *Pentabromodiacyl monobenzylhemiacetal*, $CHBr_3COC(OH)(OCH_2Ph)CBr_3$, obtained in 2-2.5 g. yield from 5 g. (a) heated 10 hrs. on the H_2O bath with 5-6 g. $PhCH_2OH$, thick rhombic prisms from ligroin, m. $109-10^{\circ}$, more stable towards alkalis than the hemiacetals of (a), as $Ba(OH)_2$ does not attack it after 2 days in the cold and $NaOH$ decomp. it completely only after several days, the resulting yellow oil containing no $CHBr_3$; it crysts. unchanged from Ac_2O . $m-O_2NC_6H_4CH_2OH$ heated on the H_2O bath with (a) gives $(O_2NC_6H_4CH_2)_3O$; $PhOH$ yields a black mass. Allowed to stand 4-5 hrs. at room temp. in acetone and then to evap. spontaneously, (a) gives $(COCHBr_3)_2$; this is also obtained from 1 g. (a) moistened with H_2O and shaken with 2 cc. of const. boiling HI. *Pentabromodiacyl monoethylhemiacetal*, obtained together with (c) from 10 g. (a) allowed to stand 5-8 weeks in 150 cc. alc. and 15 cc. acetone, short, broad prisms from petr. ether, m. 115° , does not give $CHBr_3$ with $NaOH$. The corresponding Me compd. could not be obtained. When 3 g. KI in 25 cc. H_2O are treated with 1 g. (a), a brown color appears, CO_2 is evolved and in 2 days a cryst. ppt. is formed which, after washing with KI and drying on clay, seps. from CCl_4 in slender, lemon-yellow needles, turns brown in the light, m. $122-5^{\circ}$ (decompn.) but the m. p. varies greatly with the conditions of heating; org. solvents decomp. it somewhat with liberation of I; cold fuming and hot concd. HNO_3 and hot HNO_3 dild. with $AcOH$ liberate I; NH_4OH and KOH give CHI_3 , to judge by the smell; H_2O has no action. Its compn. (Br + I, 90.28-90.44, C 7.59-7.67, H 0.61-0.78%) and mol. wt. (475-502) correspond approx. to the formula $C_6H_5OBrI_2$.

CHAS. A. ROUILLER.

Normal nonane. LATHAM CLARKE AND ROGER ADAMS. *J. Am. Chem. Soc.* 37, 2536-8(1915).—3-Nonanol, $b_{718} 192-3^{\circ}$, was obtained in 45 g. yield from 57 g. enanthole (which in turn was prepd. through the $NaHSO_3$ compd. from the fraction of castor oil b. $90-180^{\circ}$) and $EtMgBr$; this with I and red P gave 3-iodononane which, refluxed 1 hr. with excess of concd. alc. KOH , yielded *nonylene*, b. $149.4-9.9^{\circ}$, $d_{15}^{15} 0.7540$; its vapor passed together with H over freshly reduced Ni at 160° yielded nonane, $b_{718} 150.4-0.6^{\circ}$, $d_{15}^{15} 0.7219$, $n_D^{25} 1.4025$.

CHAS. A. ROUILLER.

Constitution of the nitro- α -carbopyrrolic acids. WILLIAM J. HALE AND WILLIAM V. HORT. *J. Am. Chem. Soc.* 37, 2538-52(1915).—From 1.6 g. of $\text{NaON}(:\text{O}):C(\text{CHO})_2$ (a) and 1.4 g. of $\text{HCl}\cdot\text{H}_2\text{NCH}_2\text{CO}_2\text{Et}$ (b) in 6-7 cc. of 70% alc. gently warmed for a few min. on the H_2O bath and, after soln. is complete, allowed to stand at room temp. 15-30 min., there seps. 80% of ethyl β -aldehydo- β -nitroethylideneaminoacetate, $\text{OHCCH}(\text{NO}_2)\text{CH}:\text{NCH}_2\text{CO}_2\text{Et}$, thin pale yellow prisms from alc. or H_2O , m. 104° , does not give primary or secondary amine tests, reduces $\text{NH}_4\text{-AgNO}_3$, gives a cryst. phenylhydrazone, very stable towards acids, crystg. well from concd. HCl , practically unattacked by very dil. alkalies; when, however, 1 g. in 8 cc. of 65% alc. and 40 drops of 20% NaOH is warmed not above 50° , it gives, through the intermediate $\text{O}_2\text{NCH}_2\text{CH}:\text{N}\cdot\text{C}(\text{CO}_2\text{Et})\text{CH}$, 90% of ethyl β' -nitro- α -carbopyrrolate, prisms from alc.,

m. 174° , also obtained directly, in 75% yield, from the mixt. of (a) and (b) in alc. kept 0.5 hr. at 50° with 40 drops of 20% NaOH ; 1 g. in 15 cc. of 20% KOH heated 5-6 hrs. on a H_2O bath, cooled, neutralized with concd. HCl and extd. with Et_2O , yielded 90% of the free acid (c), needles with 1 H_2O , m. 217° (decompn.), identical with Anderlini's acid (*Gazz. chim. ital.* 19, 93 (1889)), thus establishing the structure of the latter. This is further confirmed by the fact that the methyl ester, obtained from (a) and $\text{MeO}_2\text{CCH}_2\text{NH}_2\cdot\text{HCl}$, prisms from alc., m. 198° , is identical with his ester. Potassium salt, from the acid and K_2CO_3 , light yellow needles or prisms. Silver salt, yellow flocculent ppt. Of the isomeric β - and α' - NO_2 acids, the former must give on loss of CO_2 the same nitropyrrole as (c) and in this way it was shown that Ciamician's acid (*Gazz. chim. ital.* 12, 39 (1882)) is β -nitro- α -carbopyrrolic acid (d), needles with 1 H_2O , m. (anhydrous) 146° ; methyl ester, from the Ag salt and MeI heated 1 hr., m. 162° . Consequently the 3rd isomer (Anderlini, *Gazz. chim. ital.* 19, 350(1889)) is α' -nitrocarbopyrrolic acid, seps. with 1 H_2O , m. (anhydrous) 161° . Attempts to decomp. the acids into CO_2 and nitropyrroles led to many failures; heating alone led to explosive decompns.; with pumice, lime, soda-lime, sand, finely divided Cu , Ni and other metals, (c) gave unsatisfactory results; distn. *in vacuo* was more satisfactory but the yield was very small; finally, equal quantities of (c) or (d) and C_{10}H_8 were heated in sealed tubes up to, and not beyond, the charring point, and the product digested with ice H_2O for a few min., the resulting yellow soln. depositing on spontaneous evapn. β -nitropyrrole (e), while the insol. portion, when dissolved in hot H_2O and evapd. spontaneously, deposited a dimolecular form (f) of (e). The α' - NO_2 acid similarly heated with C_{10}H_8 gave a yellow oily NO_2 compd. which could not be purified. (e), small prisms, m. 63.5° , is identical with Angeli and Alessandri's product (*C. A.* 5, 3403). Heated for a short time a little above its m. p. it passes over into (f), pale yellow prisms from H_2O , m. 101° ; its mol. wt. in boiling C_6H_6 is 222 (calcd., 224) but in freezing H_2O it is considerably dissociated (mol. wt. 161.3). CHAS. A. ROUILLER.

Some salts of the haloacetic acids. II. W. G. BATEMAN AND D. B. CONRAD. *J. Am. Chem. Soc.* 37, 2553-60(1915); cf. *C. A.* 9, 454.—Ammonium dichloroacetate, from the acid and NH_3 gas in abs. Et_2O , lustrous, pearly leaflets, non-deliquescent, has a faint halogen odor, is quite stable, forms a neutral aq. soln. which soon becomes acid, volatilizes on cautious heating in white fumes having the odor of NH_3 , decomp. on higher heating into $\text{CHCl}_3\text{CO}_2\text{H}$, NH_3 and CO_2 ; dry HCl passed into its AcOEt soln. ppts. NH_4Cl ; aq. solns. dissolve HgO and after a certain amt. has been dissolved an amorphous ppt. seps. Ammonium bromoacetate, leaflets. Cupric dichloroacetate, $\text{Cu}(\text{O}_2\text{CCHCl}_2)_2\cdot 4\text{H}_2\text{O}$, from CuCO_3 and a concd. aq. soln. of the acid allowed to stand some time, filtered, treated with alc. and allowed to stand, deep blue needles, passing on standing or warming into the anhydrous form, pale blue-green microneedles; another bright green hydrate exists between these 2 forms. The tetrahydrate forms blue solns.

in H_2O , EtOH and AcOEt and green solns. in acetone, AcOH , CHCl_3 , CO_2H and Et_2O , while the anhydrous salt forms blue solns. in H_2O and green solns. in other solvents; it m. above 100° , slowly gives off acid, increases in bulk and changes in appearance. *Cupric trichloroacetate*, medium blue crystals with 3 H_2O , forming blue solns. (blue-green in Et_2O and AcOH); after several hrs. at 103° it yields the *anhydrous salt*, bright blue-green powder, sol. in alc. with green color. With alc. PhNHNH_2 , Cu salts of the haloacetic acids give olive ppts. which quickly decomp. with evolution of N; next long, white needles sep. which in the air or in contact with H_2O turn Cu-red and in NH_4OH form colorless solns. which on shaking with air become green and finally blue, while HCl solns. quickly become brown; if the PhNHNH_2 is used in excess and the mixt. is allowed to become hot, Cu_2O and sometimes apparently free Cu are formed; still other substances are sometimes found (C_6H_4 , Ph_2NH , the Et ester of the acid, CH_3CICHO , PhCl). *Cupric bromoacetate*, dark green crystals with 1 H_2O ; *anhydrous salt*, blue-green, becomes brown in H_2O on the water bath, with formation of CuBr_2 . *Mercuric chloroacetate*, from HgO and excess of the acid in hot H_2O , leaflets from hot soln., gives with H_2S in AcOEt a bright orange ppt. quickly becoming black; with NH_3 in AcOEt it is reduced to metallic Hg; it begins to m. 135° , b. 140° , turning pink, blackens 185° and at 190° mostly free Hg is left; with NH_4OH is pptd. a white powder which becomes yellow on spare washing and drying and contains about 85% Hg and about 0.25% N. *Mercuric trichloroacetate* was apparently obtained as shining needles collecting at the top of the liquid by slowly adding HgO to the acid in H_2O , but they almost immediately fall to the bottom of the vessel as a white powder consisting of almost pure Hg_2Cl_2 . *Mercurous trichloroacetate* from the acid and fresh aq. HgNO_3 , needles from H_2O ; H_2S in C_6H_4 gives a ppt. of HgS and Hg; the salt is at once decompd. by NH_4OH and it volatilizes above 200° with very little decompn. *Mercurous chloroacetate*, needles, decompd. by NH_4OH , darkens when heated in the presence of H_2O vapor and, dry, m. 180° with some decompn. *Mercurous bromoacetate*, amorphous powder, darkens 145° , becomes yellow (liberation of Br) and sublims without melting. No mercurous or mercuric dichloroacetate could be isolated. C. A. ROULLER.

Action of aluminium chloride on the aliphatic ethers. G. B. FRANKFORTER AND E. A. DANIELS. *J. Am. Chem. Soc.* 37, 2560-7 (1915); cf. *Bull.* 2, *Chem. Studies, Univ. Minn.*—The reaction between aliphatic ethers and CCl_3CHO in the presence of AlCl_3 is entirely different from that observed with aromatic ethers. The ether must be perfectly dry, as the presence of H_2O completely changes the course of the reaction. To a mixt. of Et_2O and CCl_3CHO at 0° powdered AlCl_3 was added in 5 g. portions until a small amt. of AlCl_3 remained undissolved; much heat was generated, a little HCl was evolved and the soln. became straw-yellow; after standing 2 hrs. in ice, it was allowed to rise slowly to room temp., when it became reddish brown. After standing overnight at 0° , the resulting light brown jelly was treated with H_2O and the thick brown mass which sep'd. was steam-distd., several substances being obtained but in too small amt. for careful examn. The viscous insol. material remaining in the distg. flask on treatment with Et_2O left a gelatinous substance consisting of a simple Al compd. while the Et_2O ext., distd. *in vacuo*, gave crystals, b_m 52° (evidently $\text{CCl}_3\text{CHO} \cdot \text{H}_2\text{O}$), a small amt. of liquid b_m $62-80^\circ$, and another small amt. of liquid b_m 125° , while the residue was dark brown and apparently charred. When the reaction was carried out at -8° instead of 0° , the vacuum distn. gave a small amt. of liquid at 100° , together with much HCl , and crystals between $110-135^\circ$; these m. $22-4^\circ$ and liquefied in the air. When Et_2O is treated with 1.5 parts AlCl_3 (best in pieces about the size of a pea), first at about 15° and then at $35-50^\circ$ with frequent shaking, and then thoroughly cooled, large plates sep. which, after several recrystns. from Et_2O and drying over H_2SO_4 , contain 14.9% Al and 50.8% Cl (calcd. for $\text{AlCl}_3 \cdot \text{Et}_2\text{O}$, 13.01 and 51.3%,

resp.), fairly stable over H_2SO_4 , although they slowly lose Et_2O and HCl (2.7 and 6.1% in 6 and 38 days, resp.); in H_2O , both Et_2O and HCl are liberated and the residue left by evap., the soln. contains 32% Al and 16% Cl . If the crystals are heated to const. wt. at 106° they lose 55% in wt. and the residue contains practically the same amts. of Al and Cl (32.85 and 17.27%) as the residue from the aq. soln., so that a basic Al salt, probably a mixt. having approx. the compn. $3\text{Al}(\text{OH})_3 \cdot 2\text{Al}(\text{OH})_2\text{Cl}$ is evidently formed. On exposure to the air, the crystals liquefy, then a scum forms on the surface and finally the whole changes to a slightly yellow solid; there is a gradual increase in wt., then a loss and finally a fluctuation with atmospheric conditions (in 1 case a max. increase of 17.9% in 12 days, decreasing to 7.3% in 28 days); over H_2O in a closed vessel there is a very rapid increase in wt. (11.6, 38.1 and 238% after 8 hrs., 29 hrs. and 15 days, resp., with a 5% loss of Cl). Pr_2O instead of Et_2O gives an additive compd. as a red liquid (found, 15.73% Al and 42.61% Cl). While AlCl_3 dissolves clear in absolutely dry Et_2O , a trace of H_2O will form a cloud or ppt., and this reaction may be used as a qual. test for the presence of H_2O ; into 5-10 cc. Et_2O at 10° in a stoppered test tube is dropped a piece of fresh AlCl_3 the size of a wheat kernel; as the Et_2O warms to room temp., reaction takes place and minute bubbles rise to the top, carrying with them, in the presence of H_2O , a delicate white cloud; 7% of alc. will cover the test but not 5%; Et_2O dried over CaCl_2 will give a positive test; 1 drop of H_2O in 500 cc. of Et_2O freshly distd. over Na can be detected in this way. C. A. ROULLER.

Veratrine and some of its derivatives. II. GEO. B. FRANKFORTER AND W. KRITCHEVSKY. *J. Am. Chem. Soc.* 37, 2567-9(1915); cf. *Am. Chem. J.* 20, 358.—The following compds. were prepd. by treating the alkaloid in CS_2 with CCl_3CHO , adding cold Et_2O after the reaction had ceased, filtering, washing several times with Et_2O and drying. Heated several hrs. at $130-40^\circ$, they lose the CCl_3CHO , showing that these compds. are simple additive products. By changing the amt. of CCl_3CHO used, the ratio between the components of the compds. can be varied. *Cevadine-chloral*, $2\text{C}_{27}\text{H}_{49}\text{O}_8\text{N} \cdot \text{CCl}_3\text{CHO}$, amorphous, m. 220° ; $2\text{C}_{27}\text{H}_{49}\text{O}_8\text{N} \cdot 3\text{CCl}_3\text{CHO}$, m. 209° . *Cevine-chloral*, $\text{C}_{27}\text{H}_{49}\text{O}_8\text{N} \cdot \text{CCl}_3\text{CHO}$, m. $206-8^\circ$. *Cevadine-bromal*, $2\text{C}_{27}\text{H}_{49}\text{O}_8\text{N} \cdot \text{CBr}_3\text{CHO}$, bright yellow powder, m. 162° . *Cevine-bromal*, $2\text{C}_{27}\text{H}_{49}\text{O}_8\text{N} \cdot \text{CBr}_3\text{CHO}$, bright yellow powder, m. 106° . Every alkaloid sol. in CS_2 thus far studied similarly gives with CCl_3CHO or CBr_3CHO additive compds. insol. in Et_2O . C. A. ROULLER.

Triphenylmethyl. XXIV. The additive compounds of triphenylmethyl and some saturated hydrocarbons. M. GOMBERG AND C. S. SCHOEFFLE. *J. Am. Chem. Soc.* 37, 2569-74(1915); cf. *C. A.* 8, 1689.—Inasmuch as in the expts. in which the formation of additive compds. between Ph_3C and satd. hydrocarbons was indicated (*Ber.* 38, 1338(1905)) the hydrocarbons used were merely purified samples of petr. ethers and it was not entirely impossible that they still contained small amts. of olefin compds., the expts. have been repeated with carefully purified individual paraffins of natural origin and also some synthetic aliphatic and alicyclic hydrocarbons. The hexane and heptane (from petroleum) were shaken 10 hrs. each with concd. H_2SO_4 and concd. HNO_3 and 6 hrs. with alk. KMnO_4 before drying and fractionating; the synthetic octane and diisooamyl were also shaken with H_2SO_4 ; the cyclohexane and methylcyclohexane were carefully distd. The Ph_3C was prepd. by shaking 10 g. Ph_2CCl , 10 g. Hg and 0.5 g. Pb powder in about 75 cc. C_6H_6 for several hrs., allowing to settle, siphoning off the clear liquid, distg. the C_6H_6 *in vacuo*, crystg. from acetone and drying in CO_2 and finally *in vacuo*. To prep. the additive compds., about 60 cc. of the hydrocarbon and the Ph_3C are heated to the b. p., filtered and cooled; the mother liquors are drawn off from the resulting compds., which usually sep. in colorless crystals; these, after drying in CO_2 and *in vacuo*, are heated at $80-110^\circ$ for 1-1.5 hrs. in a slow stream of CO_2 ; the loss in wt. they thereby undergo corresponds in each case to the amt.

of hydrocarbon combined with the Ph_2C and unchanged Ph_2C remains in the boat. Only when the heating is carried out at 100° or higher and for a considerable length of time does the distillate contain a small amt. (seldom more than 1%) of a substance which reduces KMnO_4 . Examn. of the tabulated results shows that the formation of additive compds. depends on several factors. The foremost is undoubtedly the temp. at which the compd. dissociates, and the 2nd the relative solubility of Ph_2C in the hydrocarbon in question; the higher the temp. of dissociation of the compd. and the greater the solubility of the Ph_2C , the better are the chances that an additive compd. will sep. on cooling. With decane the additive compd. appears to consist of *monomol.* Ph_2C in combination with the solvent. No explanation based upon the valence hypothesis can satisfactorily account for the formation of these compds. with completely satd. hydrocarbons. XXV. Preparation of *p*-hydroxytriphenylcarbinol and attempts to isolate the corresponding triarylmethyl. M. GOMBERG AND R. L. JICKLING. *Ibid* 2575-91; cf. *C. A.* 7, 3507.—By observing the proper conditions, it is possible to obtain from Ph_2CCl_2 and PhOH almost exclusively 1 of the 3 products, $\text{Ph}_2\text{C}(\text{OPh})_2$, $p\text{-HOC}_6\text{H}_4\text{CPh}_2\text{OH}$ or $(p\text{-HOC}_6\text{H}_4)_2\text{CPh}_2$. Ph_2CCl_2 itself is obtained in 90% yield by adding to 135 g. finely-divided AlCl_3 in 300 cc. CS_2 156 g. C_6H_6 and an equal vol. of CCl_4 in the course of 1 hr., keeping the temp. below 30° , decomp. the next day with *ix.* drying the CCl_4 soln. with CaCl_2 , distg. *in vacuo* and redistg. *in vacuo* with the calcd. amt. of PCl_5 to react with the 5-10% of BzPh in the original distillate. When molten PhOH is slowly added to an equal wt. of Ph_2CCl_2 in about 10 vols. of C_6H_6 at 50° , the HCl being removed, as fast as it is formed, by a current of dry air under a slight vacuum, and the soln. is concd. and treated with petr. ether, $\text{Ph}_2\text{C}(\text{OPh})_2$ seps. in 85% yield in needles, m. 132° after crystn. from alc., unchanged by boiling H_2O or *N* alkali, hydrolyzed by dil. acids, even AcOH , into BzPh and PhOH . When to 3-4 mols. molten PhOH chilled in a flask so as to be evenly distributed over the inner surface is added 1 mol. Ph_2CCl_2 (the mouth of the flask being protected with a CaCl_2 tube) and, after 10 hrs. at $20-3^\circ$ with occasional rotations, the mass is steam distd. to remove the excess of PhOH , digested with 5% alkali, freed from BzPh with Et_2O , filtered, freed from Et_2O with air and treated with NH_4Cl or CO_2 , there is obtained a paste, soon becoming granular, of $\text{HOC}_6\text{H}_4\text{CPh}_2\text{OH}$ and a little $\text{Ph}_2\text{C}(\text{C}_6\text{H}_4\text{OH})_2$; the former is dissolved out by treating the mass with alc. (6 cc. per g.; the filtration may be facilitated by adding a few cc. of concd. sugar soln.); addition of H_2O and a few drops of NH_4OH to the filtrate ppts. the carbinol (90-8% yield) in cryst. form. In the prepn. of $\text{Ph}_2\text{C}(\text{C}_6\text{H}_4\text{OH})_2$ by heating PhOH with Ph_2CCl_2 the use of PhONa in PhOH is without advantage nor is the long heating recommended by Zincke (*C. A.* 3, 786) necessary; 90-5% yields are obtained after several hrs. It seps. from AcOH in flakes or needles, m. 286° . G. and J. believe that, whatever the conditions, the 1st stage in the reaction between Ph_2CCl_2 and PhOH consists in the formation of $\text{Ph}_2\text{C}(\text{OPh})_2$ and HCl , and if the HCl is removed the reaction stops at this point. Otherwise, 1 of the OPh groups undergoes a mol. rearrangement, and the resulting $\text{Ph}_2\text{C}(\text{OPh})\text{C}_6\text{H}_4\text{OH}$ with HCl gives to some extent $\text{Ph}_2\text{CClC}_6\text{H}_4\text{OH}$. If the reaction is allowed to proceed still further, the 2nd OPh group rearranges, giving $\text{Ph}_2\text{C}(\text{C}_6\text{H}_4\text{OH})_2$, and the $\text{Ph}_2\text{CClC}_6\text{H}_4\text{OH}$ always formed in variable but small amt. condenses with PhOH , likewise giving $\text{Ph}_2\text{C}(\text{C}_6\text{H}_4\text{OH})_2$. That the intermediate compds. can react as above has been verified experimentally, and all of them, except the $\text{Ph}_2\text{C}(\text{OPh})\text{C}_6\text{H}_4\text{OH}$, have been isolated. Indirect evidence that this is really an intermediate product is afforded by the fact that an approx. quant. yield of $\text{HOC}_6\text{H}_4\text{CPh}_2\text{OH}$ is obtained only when 2 mols. PhOH per mol. Ph_2CCl_2 are used, whereas if the reaction proceeded according to the simple scheme $\text{Ph}_2\text{CCl}_2 + \text{PhOH} \rightarrow \text{Ph}_2\text{CClC}_6\text{H}_4\text{OH} \rightarrow \text{Ph}_2\text{C}(\text{OH})\text{C}_6\text{H}_4\text{OH}$, 1 mol. PhOH should be sufficient. In attempting to prep. the free radical, $p\text{-HOC}_6\text{H}_4\text{CPh}_2$,

the carbinol chloride cannot be used, for with mol. Ag it splits off HCl instead of Cl, probably because the Cl and OH are combined with the same C atom, there being an

equil. between the 2 tautomeric forms: $\text{Ph}_2\text{CClC}_6\text{H}_4\text{OH} \rightleftharpoons \text{Ph}_2\text{C}:\text{C}_6\text{H}_4\text{:}$  To

protect the HO group, therefore, *p*-carboethoxytriphenylcarbinol, $\text{EtO}_2\text{COC}_6\text{H}_4\text{CPh}_2\text{OH}$, was prepd. from 14 g. $\text{HOC}_6\text{H}_4\text{CPh}_2\text{OH}$ in 55 cc. of *N* NaOH and ice treated with 6 g. ClCO_2Et , needles from C_6H_6 , Et_2O , etc. + petr. ether, m. 119° (yield, quant.); with HCl in C_6H_6 in the presence of CaCl_2 it gives the chloride, m. 98° ; a C_6H_6 soln. of this, protected from the air and treated with mol. Ag, becomes dark cherry-red after several hrs. and on exposure to the air the color disappears; concn. of the filtered soln. yields a small amt. of peroxide, m. 171° , obtained in much better yield by boiling the chloride in C_6H_6 with Ag in a stream of air; attempts to obtain the dihydroxy peroxide by hydrolyzing off the EtO_2CO groups resulted in decompn. into either $\text{EtO}_2\text{COC}_6\text{H}_4\text{CPh}_2\text{OH}$ or $\text{HOC}_6\text{H}_4\text{CPh}_2\text{OH}$, the former being obtained in good yield by warming the peroxide with $\text{AcOH-H}_2\text{SO}_4$ (4:1). Boiling *N* alkali does not attack the peroxide, but NaOEt or KOH or Ba(OH)_2 in MeOH decomp. it into $\text{HOC}_6\text{H}_4\text{CPh}_2\text{OH}$. The colored soln. of the free radical, concd. in CO_2 , yields a colorless residue entirely devoid of unsatd. properties and no longer yielding a peroxide on exposure to the air, either as the solid or in soln. This colorless product is obtained to a greater or lesser extent in the prepn. of the peroxide, especially if the soln. of the free radical is kept for some time previous to the oxidation or if it is heated. It is an amorphous powder m. about 280° , mol. wt. (Menzies method) 680, 664, and is probably a metamer resulting from a transformation of the dimol. form of the free radical. All other attempts to prep. the free radical (by changing the solvent, using Hg or Cu instead of Ag, concg. at very low temps. and pressures, etc.) gave the same result. *p*-Bensoxytriphenylcarbinyl chloride, m. 105° . *p*-Bensoxytriphenylmethyl peroxide, m. 167° (decompn.). The free radical could not be isolated, only the colorless metamer being obtained; it m. $266-9^\circ$, mol. wt. 710. *p*- $\text{AcOC}_6\text{H}_4\text{CPh}_2\text{Cl}$ is best prepd. by heating the carbinol in excess of AcCl until it dissolves. *p*-Acetoxytriphenylmethyl peroxide, m. 172° . Polymer of the free radical, m. $255-70^\circ$ (decompn.). *p*-Carboethoxytriphenylmethyl ether, from 10 g. of the chloride, 30 g. HgO and 50 cc. C_6H_6 shaken 1 month at room temp., m. 219° , hydrolyzed to the carbinol by boiling in AcOH or alc. containing a few drops of H_2SO_4 ; thus far, it has not been possible to remove the EtO_2CO groups only. CHAS. A. ROULLER.

Pyrimidines. LXXVII. The alkylation of 2-mercaptopyrimidines. TREAT B. JOHNSON and ROBERT C. MORAN. *J. Am. Chem. Soc.* 37, 2591-7 (1915); cf. C. A. 9, 1066.—The assumption (drawn from the results obtained by the study of 2-allylmercapto-4-methyl-6-oxypyrimidine) that the more negative the group substituted for a H of the Me in a 2-methylmercaptopyrimidine the less tendency will there be for an alkyl halide to form a 1-*N*-alkyl deriv. and the greater will the amt. of *O*-compd. formed be is confirmed by the work reported in this paper. 1,4-Dimethyl-2-benzoylmethylmercapto-6-oxypyrimidine, obtained in 2.8 g. yield from 5 g. 2-benzoylmethylmercapto-4-methyl-6-oxypyrimidine (a), 0.44 g. Na in 50 cc. alc. and 2.73 g. MeI heated on the H_2O bath until neutral, prisms from alc., m. 155° , hydrolyzed by boiling 1 hr. with concd. HCl to 2,5-diphenyl-1,4-dithiene (b) and 1,4-dimethyluracil. When 2.5 g. EtBr is used instead of MeI, the product is 2-benzoylmercapto-4-methyl-6-ethoxyypyrimidine (c), seps. from AcOEt in flat prisms with 1 mol. solvent of crystn., m. 83.5° , hydrolyzed by HCl to (b) and 4-methyluracil. Under the same conditions, (a), Na in alc. and PhCH_2Cl give (c) and none of the expected PhCH_2 deriv., while in MeOH instead of EtOH is obtained 2-benzoylmethylmercapto-4-methyl-6-methoxyypyrimidine (d), slender needles from AcOEt , m. $143-4^\circ$, hydrolyzed by HCl to (b) and 4-methyluracil, cannot

be converted into (c) by warming with EtOH. J. and M. believe that the PhCH_2 deriv. $\text{CH:CMe.N:C(SCH}_2\text{Bz).N:COCH}_2\text{Ph}$ is 1st formed and with the solvent

(ROH) gives an addition compd., $\text{CH:CMe.N:C(SCH}_2\text{Bz).NH.C(OR)OCH}_2\text{Ph}$,

which then loses PhCH_2OH and yields (c) or (d), according as R is Et or Me. (a) could not be alkylated with $\text{ClCH}_2\text{CO}_2\text{Et}$ in alc. CHAS. A. ROUILLER.

Nitrated proteins. IV. Identification of 3-nitrotyrosine among the products of hydrolysis of nitrated fibroin. TREAR B. JOHNSON. *J. Am. Chem. Soc.* 37, 2598-603 (1915).—Repetition of Inouye's work (*C. A.* 7, 802) has shown that, as stated by him, nitrotyrosine is formed by hydrolysis of nitrated fibroin; the compd. is partly pptd. by phosphotungstic acid, the filtrate containing more of the same acid; it is identical with J. and Kohmann's 4,3- $\text{HO(O}_2\text{N)C}_6\text{H}_3\text{CH}_2\text{CH(NH}_2\text{)CO}_2\text{H}$ (*C. A.* 9, 2657), the structure of which was further established by treating it with NH_4SCN in the presence of Ac_2O and hydrolyzing the resulting product with HCl, giving 2-thio-4-[3-nitro-4-hydroxybenzyl]hydantoin. CHAS. A. ROUILLER.

Change of ammonium isethionate by heating. K. MIYAKE. *J. Am. Chem. Soc.* 37, 2604 (1915).—M. has repeatedly attempted, without success, to obtain taurine by heating $\text{HOCH}_2\text{CH}_2\text{SO}_3\text{NH}_4$ at 220° (Strecker, *Ann.* 91, 97 (1854)), and he concludes that the reaction follows the course reported by Carl (formation of $\text{HOCH}_2\text{CH}_2\text{SO}_3\text{CH}_2\text{CH}_2\text{SO}_3\text{NH}_4$; *Ber.* 12, 1604 (1879)), not that given by S. C. A. R.

Phenyl esters of oxalic acid. ROGER ADAMS AND H. GILMAN. *J. Am. Chem. Soc.* 37, 2716-20 (1915).—Any type of substituted Ph ester of $(\text{CO}_2\text{H})_2$ can be obtained in practically quant. yield by slowly adding 5 g. $(\text{COCl})_2$ to 25 cc. of ice-cold $\text{C}_6\text{H}_5\text{N}$, carefully crushing the resulting yellow lumps, gradually adding 2 mols. of the phenol in a little $\text{C}_6\text{H}_5\text{N}$, allowing to stand 2 hrs. or more at 0° , pouring into concd. HCl and ice, filtering, washing with H_2O , and (unless polyphenols or HO acids have been used) removing any unchanged phenol remaining with cold dil. NaOH. In this way were prepd. the di-*p*-cresyl, - α - and - β -naphthyl and -guaiacyl esters (Bischoff, *Ber.* 35, 3443 (1902)) and the following new esters: *Di-o-nitrophenyl*, flat yellow needles from C_6H_6 , m. 185° . *Di-o-aldehydophenyl*, plates from C_6H_6 , m. $153-4^\circ$. *Divanillin*, m. $203-4^\circ$. *Di- β -acetyl- α -naphthyl*, leaves from C_6H_6 , m. 197° . *Di-o-carbomethoxyphenyl*, needles from C_6H_6 , m. 158° . *Di-p-hydroxyphenyl*, white powder, begins to shrink 192° , m. 212° , sol. in dil. NaOH with yellow color. When the reaction between $(\text{COCl})_2$, $\text{C}_6\text{H}_5\text{N}$ and *o*- $\text{HOC}_6\text{H}_4\text{CHO}$ was carried out at the boiling temp. of the $\text{C}_6\text{H}_5\text{N}$, the product was $\text{O(C}_6\text{H}_4\text{CHO})_2$ instead of the above ester. *o*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$ gave a white solid containing N, undoubtedly the $\text{C}_6\text{H}_5\text{N}$ salt of the ester which had not been decompd. by the concd. HCl; hot HCl or NaOH set free the $\text{C}_6\text{H}_4\text{N}$ but also hydrolyzed the ester. If the *p*- $\text{C}_6\text{H}_4(\text{OH})_2$ is added to the $(\text{COCl})_2$ and $\text{C}_6\text{H}_5\text{N}$ at room temp. and the mixt. is allowed to warm up from the heat of reaction, several products are formed; one of these, by treatment with glacial AcOH, is obtained in white needles, m. 226° , having a comp. agreeing well with that calcd. for *di-p-hydroxyphenyl ether monoacetate* (found, 68.9% C, 4.7% H). CHAS. A. ROUILLER.

Monoacetyltrichlorotertiarybutyl alcohol (acetylchloreton). T. B. ALDRICH. J. Am. Chem. Soc. 37, 2720-3 (1915).—*Trichlorotertiarybutyl acetate* (a), $\text{CCl}_3\text{CMe}_2\text{OAc}$, obtained from chloreton (b) boiled 2 hrs. with 2 parts Ac_2O and 1 part NaOAc, cooled, neutralized with Na_2CO_3 , distd. with steam, heated 20 min. on the H_2O bath with 10% NaOH to decomp. unchanged (b) and extd. with Et_2O , b_m , $151-2^\circ$; 3 cc. heated 3 hrs. at 160° with 10 cc. H_2O is apparently unchanged; 3 more hrs. heating at 250° produces complete decompn. (partial carbonization, acid reaction, formation of a ppt., sol. in NH_4OH , with AgNO_3 , no evidence of (b)); 8 hrs. heating at 160° of 2 cc. of (a) with

25 cc. H_2O gives 0.5 cc. of a reddish brown oil and a slightly yellow, acid supernatant liquid giving with $AgNO_3$ a voluminous ppt. sol. in NH_4OH ; long boiling of (a) with H_2O (108 hrs.) gives some crystals of (b); considerable of this is obtained after 7 hrs. boiling with H_2O containing H_2SO_4 , and a large amt. after boiling a few min. with concd. HNO_3 . The solubilities of (a) are practically the same as those of (b), it being even less sol. in H_2O ; it is less volatile than (b); it has anesthetic properties similar to those of (b), but, being so slightly sol., its effect does not appear for several hrs. It has a more agreeable odor than (b); its toxicity, when injected subcutaneously into guinea pigs, is slightly less than that of (b).

CHAS. A. ROULLER.

Synthesis of certain substituted syringic acids. MARSTON T. BOGERT AND EDWARD PLAUT. *J. Am. Chem. Soc.* 37, 2723-33(1915); cf. *C. A.* 8, 3789.—(The m. ps. given below are corr.) B. and P. have been able to cryst. Hamburg's oily Me bromotrimethylgallate (*Monatsh.* 19, 596(1898)) from Et_2O in prisms, m. 90° ; the bromination is best effected by gradually treating 10 g. of the $(MeO)_3C_6H_2CO_2Me$ (a) in 60 g. cold Ac_2O with 13 g. Br in 60 cc. Ac_2O and allowing to stand 24 hrs. $O_2N(MeO)_3C_6HCO_2Me$, obtained in 80% yield from 30 g. (a) in 120 cc. cold Ac_2O slowly treated with 20 cc. concd. and 1 cc. fuming HNO_3 , pale yellow prisms from ligroin, m. 67.8° . *Ethyl syringate*, obtained in 85% yield from the acid and alc. HCl, m. 55.8° . *Isoamyl ester*, needles from $EtOH$, m. 101° . *Methyl acetylsyringate*, in 95% yield from 5 g. Me syringate (b) allowed to stand 24 hrs. in 15 g. Ac_2O , m. 129° . Me bromosyringate (Graebe and Martz, *Ber.* 36, 216, 1031(1903)) can be smoothly obtained from 10 g. (b) in 100 cc. Ac_2O at 0° slowly treated with 12 g. Br in 60 cc. Ac_2O and allowed to stand overnight. *3,4-Dinitropyrogallol 2,6-dimethyl ether*, pale yellow, m. 154° , sol. in alkalis, is the main product of the reaction of concd. HNO_3 on syringic acid in cold $AcOH$. *Methyl nitrosyringate*, obtained in 75-80% yield from 18 g. (b) in 100 cc. of Ac_2O slowly treated below 0° with 18 cc. concd. HNO_3 containing a little fuming acid, or in 30% yield from $O_2N(MeO)_3C_6HCO_2Me$ heated with 48% HBr, pale yellow, m. 68.3° . *Ethyl ester*, silky needles from ligroin, m. 74° . *Methyl aminosyringate*, m. 110° , is obtained in 65% yield as its hydrochloride (c), needles, m. 192° , by reducing 10 g. of the NO_2 ester, moistened with alc., with 15 g. Sn and 50 cc. of 33% HCl, first at 0° and finally at 100° and decomp. the resulting double salt with H_2S in HCl. *Diacetyl derivative*, obtained in 4.7 g. yield from 3 g. of the NH_2 ester warmed with 15 cc. of Ac_2O and 0.5 g. NaOAc, allowed to stand overnight and warmed a few min. with 100 cc. H_2O , m. 139.9° . *2,4-Dihydroxy-3,5-dimethoxybenzoic acid*, obtained in 80% yield from 5 g. of (c) in 10 g. concd. H_2SO_4 and 50 cc. H_2O diazotized with 10 g. $NaNO_2$ in 50 cc. H_2O and then heated 2 hrs. at 100° , pale yellow, m. 165° (decompn.), gives a brown color with $FeCl_3$; heated for 40 min., finally to 220° , it evolves gas and becomes purplish; if this is recrystd. from alc., shaken with NaOH and Me_2SO_4 , boiled for a short time, acidified, filtered and the ppt. crystd. from alc., there are obtained needles, m. 89° (cf. Boëris, *Ber.* 29, 1808(1896)). *Diacetyl derivative*, from 10 g. of the di-HO acid boiled a short time with 30 cc. Ac_2O and 0.5 g. NaOAc, decomp. 162° .

CHAS. A. ROULLER.

Preparation of melibiose. C. S. HUDSON AND T. S. HARDING. *J. Am. Chem. Soc.* 37, 2734-6(1915).—Melibiose has uniformly been obtained in 175-200 g. yield from 500 g. pure raffinose (*C. A.* 8, 3777) in about 10% aq. soln. (60° Ventzke in a 2 dcm. tube) treated with 10 g. of baker's yeast, 1-2 drops of $AcOH$ and 1 g. malt sprouts and allowed to stand at room temp. until fermentation is complete (36-48 hrs.) when the rotation is $46.8^\circ V$; the soln. is then cleared with a slight excess of basic Pb acetate, filtered through asbestos, treated with H_2S , then with 30-40 g. of active decolorizing carbon (such as "Eponit" or "Norit"), again filtered, the excess of H_2S removed with air, the soln. distd. *in vacuo* to a syrup with about 20-5% H_2O , 95% alc. added just below the point of pptn. of a syrupy phase and a few crystals of melibiose stirred in;

after 4 days the syrup crystals to a solid mass which is ground at room temp. with 75% alc., filtered, washed with 75 and then 95% alc. and dried in a desiccator. C. A. R.

A second crystalline *d*-fructose pentaacetate (α -*d*-fructose pentaacetate). C. S. HUDSON AND D. H. BRAUNS. *J. Am. Chem. Soc.* 37, 2736-45 (1915); cf. C. A. 9, 1771. —Fructose tetraacetate (a) is easily and cheaply obtained, in 70 g. yield, from 100 g. of very pure, finely powdered *d*-fructose added with stirring to 9 g. ZnCl_2 in 500 cc. Ac_2O at 0° , stirred 0.5 hr. each at 0° , 10° and room temp., dild. with an equal amt. of cold H_2O , the stirring continued 2 hrs. with cooling to convert the Ac_2O into AcOH , the soln. neutralized with NaHCO_3 , filtered, the ppt. and filtrate extd. with CHCl_3 , the exts. dried with CaCl_2 , concd. *in vacuo* to 30-50 cc., then concd. to crystal. in a flat dish in a current of air, with occasional additions of Et_2O and the product recrystd. by spontaneous evapn. of its $\text{EtOH-Et}_2\text{O}$ soln. (a) can also be obtained in 19-20% yield from 30 g. *d*-fructose added to 100 g. cold Ac_2O and 51 g. HBr gas. From 40 g. (a) in 600 cc. Ac_2O treated with 2 g. ZnCl_2 in small pieces and allowed to stand 24 hrs. at room temp. until the rotation changed from the initial value -85.6° to the const. value 95° , then worked up as above, is obtained 36 g. of α -*d*-fructose pentaacetate (b), different from the β -form (c), m. 108° , $[\alpha]_D^{20} -120.9^\circ$, obtained from *d*-fructose, Ac_2O and H_2SO_4 ; $z \approx 70^\circ$, crystals much less readily than (c), mol. wt. 389-410 in freezing C_6H_6 , $[\alpha]_D^{20} 34.3^\circ$ in CHCl_3 . The mother liquors from the 1st recrystns. of (b) yielded crystals m. 55.6° , $[\alpha] -19^\circ$, giving on sapon. values agreeing for a pentaacetate; they were probably a mixt. of (b) and (c). The reaction of the ZnCl_2 and Ac_2O on (a) was stopped at various points before completion to det. whether any intermediate product, possibly the hypothetical α -tetraacetate, is formed, but no evidence of such an intermediate product was obtained. (b) can be obtained directly from fructose, ZnCl_2 and Ac_2O but the yield is not so good as when (a) is the starting point (8 g. crystal. (b) from 50 g. fructose). (b) is also obtained in 1 g. yield from 10 g. fructose added to 67 cc. $\text{C}_6\text{H}_5\text{N}$ and 50 cc. Ac_2O at 0° , stirred 3 hrs. and kept 2 days in the ice chest. That (b) and (c) have the same ring formation is shown by the fact that (c) is obtained in 17 g. yield from 20 g. (a) stirred 45 min. with 120 cc. cold Ac_2O and 5 cc. concd. H_2SO_4 . No equil. can be established between (b) and (c) by the usual method of heating with ZnCl_2 in Ac_2O , nor by heating with $\text{Ac}_2\text{O-H}_2\text{SO}_4$ or boiling with Ac_2O . The same is true of (a); it does not show mutarotation in abs. or 50% alc.; addition of a few drops of AcOH to the alc. soln., raising the temp. from $3-4^\circ$ to 20° or heating with ZnCl_2 in AcOH produces no change in rotation. When 7 g. (c) in 8 cc. AcOH is made up to 25 cc. with AcOH satd. with HBr , the rotation changes from -121.7° to 45.7° , 53.6° , 59.2° , 60.5° , 60.0° , in 20, 30, 45, 65, 85 min., resp.; on shaking the product with ice H_2O and working it up as above, 3.5 g. (a) were obtained; bromotetraacetylfructose is undoubtedly formed in the reaction but cannot be isolated on account of the ease with which it is decompd. by H_2O . When (b) is similarly treated, there is no change in rotation and after 5 min. on the H_2O bath (which changes the rotation from 26.6° to 23.9° and makes the soln. turn dark yellow) treatment with H_2O , etc., yields back about 0.5 of the original (a).

CHAS. A. ROULLER.

Bromoacetylxylose and β -triacetylmethylxyloside. J. K. DALE. *J. Am. Chem. Soc.* 37, 2745-7 (1915).—The following method of prepg. bromoacetylxylose (a) has also given the corresponding lactose, maltose and glucose derivs. in 55-70% yields; mannose and galactose do not give crystal. compds. When 25 g. xylose is treated with 150 cc. of Ac_2O satd. with HBr , violent reaction takes place; the resulting straw-colored syrup, after cooling, is mixed with 300 cc. CHCl_3 , shaken with ice H_2O , NaHCO_3 , and again 3-4 times with H_2O , the CHCl_3 dried with CaCl_2 , evapd. *in vacuo* at 50° to a thick syrup, and the product recrystd. twice from Et_2O ; the (a) so obtained can be kept several hrs. without appreciable decompn.; it m. 102° , $[\alpha]_D^{20} 212.2^\circ$ in CHCl_3 ; treated

in 10 parts MeOH with AgNO₃ in 80% MeOH until the AgBr is completely pptd., filtered, treated with H₂S, shaken with NaCO₃, filtered, evapd. to a thick syrup *in vacuo* on the H₂O bath and crystd. from a little H₂O, it gives β -triacetylmethylxyloside, m. 115°, $[\alpha]_D^{20}$ -60.8° in CHCl₃, converted by shaking 2 hrs. with 0.1 N NaOH into β -methylxyloside (yield, 0.13 g. from 0.4575 g. of the Ac compd.). From 4 g. (a) in 75 cc. AcOH shaken a few min. with 5 g. of AgOAc is obtained β -tetraacetylxylose.

CHAS. A. ROULLER.

The isomeric tetracetates of xylose, and observations regarding the acetates of melibiose, trehalose and sucrose. C. S. HUDSON AND J. M. JOHNSON. *J. Am. Chem. Soc.* 37, 2748-53(1915).—When β -xylose tetracetate (a), m. 128°, $[\alpha]_D^{20}$ -24.7°, -22.3°, -7.3° in CHCl₃, C₆H₆, 99.5% AcOH, resp. (cf. Stone, *Am. Chem. J.* 15, 653 (1893); Bader, *Chem. Ztg.* 19, 55(1895)), is heated in Ac₂O containing a little ZnCl₂, the rotation changes from -23.3° to a const. value 71.8° in 4 min. or less; on pouring into H₂O the insol. syrup soon partially crysts.; the mass is thinned with alc. and the crystals (original (b)) are sepd.; the mother liquor on cooling with ice deposits flaky crystals melting somewhat below room temp. and which are apparently an unstable alcoholate of the α -xylose tetracetate (b); when dissolved in alc. at room temp., the soln. spontaneously deposits the solvent-free (b), the same change being effected when the crystals stand several days in alc. near 0°. (b), which is obtained in 50% yield, m. 59°, mol. wt. in freezing C₆H₆, 303-29, $[\alpha]_D^{20}$ 89.3°, 79.3°, 95.3° in CHCl₃, C₆H₆, 99.5% AcOH, resp. The difference in the mol. rotations of (a) and (b) in CHCl₃ is about the same (36,300) as for the α - and β -glucose pentaacetates (38,100) but in C₆H₆ and AcOH the conclusion does not hold at all well (32,500 and 32,700 for the xyloses, 36,700 and 40,800 for the glucoses; cf. C. A. 9, 1620). From 20 g. α -xylose treated at 0° with occasional stirring for 50 hrs. with 100 cc. each of Ac₂O and com. C₆H₅N bases are obtained (a) and about 9 g. of (b), probably owing to a partial transformation of the α -xylose into the β -form before the acetylation. Acetochloroxylose (cf. Ryan and Ebrill, *Proc. Roy. Dublin Soc.* 11, 249(1905-8)), obtained in 7.8 g. yield from 10 g. xylose boiled until dissolved with AcCl and a trace of ZnCl₂, m. 95-7°, $[\alpha]_D^{20}$ 165° in CHCl₃; 5 g. in 125 cc. AcOH, shaken with AgOAc until the supernatant liquid gave no test for Cl, yielded 3 g. of (a), m. 125°, $[\alpha]$ -25°. Both (a) and (b), treated at room temp. with AcOH satd. with HBr, yield acetobromoxylose (cf. preceding abstr.). β -Melibiose octaacetate, m. 177.5°, $[\alpha]$ 102.5° in CHCl₃, 101.9° in 99.5% AcOH, when heated 35 min. in Ac₂O and a little ZnCl₂ changes in rotation from 107.0° to 147.3°, and on pouring into H₂O and treating the insol. syrup with alc. there is obtained a thick syrup which after some weeks deposits a few crystals; not enough have been secured yet for measurements. Trehalose octaacetate, obtained in 60% yield from the sugar, Ac₂O and NaOAc and in 72% yield with Ac₂O and ZnCl₂, m. 96-8°, $[\alpha]_D^{20}$ 162.3° in CHCl₃; heating repeatedly to 100° in Ac₂O-ZnCl₂ does not change the rotation. The same is true of sucrose octaacetate, m. 69°, $[\alpha]_D^{20}$ 59.6° in CHCl₃.

CHAS. A. ROULLER.

Condensation of aldehyde diacetates and of phenylhydrazones with 2-thiohydantoin. BEN H. NICOLLET. *J. Am. Chem. Soc.* 37, 2753-6(1915).—Since, in the prepn. of substituted phenylalanines, starting from aldehydes and 2-thiohydantoin (a), the required aldehydes can sometimes not easily be bought or obtained pure, it seemed desirable to det. whether derivs. of the aldehydes might not be substituted for the free aldehydes themselves. It seems that the diacetates and phenylhydrazones react equally as well as the free aldehydes. Thus, 2-thio-4-benzalhydantoin is obtained in 61.3% yield from 1.7 g. (a), 3.5 g. PhCH(OAc)₂ and 5 g. NaOAc boiled 2 hrs. in 20 g. AcOH, while with 2.5 g. PhCH:NNHPh instead of PhCH(OAc)₂ the yield is 54%. From (a) boiled 2 hrs. with a slight excess of MeCH:NNHPh in AcOH and NaOAc

is obtained *2-thio-4-ethylidenekydantoin*, yellow-brown cryst. powder, m. around 253° .

CHAS. A. ROUVILLER.

Isopulegolphosphonic acid. FRANCIS D. DODGE. *J. Am. Chem. Soc.* 37, 2756-61 (1915); cf. *Am. Chem. J.* 12, 553 (1890).—The "citronellal phosphoric acid" (a), $C_{10}H_{18}O_4P$, obtained by the action of P_2O_5 on citronellal, is a strong monobasic acid, m. $181-2^{\circ}$, sepg. from alc. in plates of the monosymmetric system, $a:b:c = 1.9828:1:1.9745$, $\beta 57^{\circ}50'$, (001) ∞P , (100) $\infty \bar{P}\infty$, (011) ∞P . *Potassium salt*, plates with 3 H_2O ; no di-K salt could be obtained. *Sodium salt*, plates. The alkali salts are remarkably stable; long boiling in H_2O produces no decompn. *Magnesium and calcium salts*. *Silver salt*, curdy ppt. soon becoming cryst. The Na salt, heated cautiously until white fumes appear, cooled, treated with a little H_2O , distd. to dryness, again heated to fuming, etc., until no more oil is obtained, gives $NaPO_3$ and what is most probably isopulegol (b). (a) is not hydrolyzed by hot alc. KOH or dil. H_2SO_4 and must therefore be regarded as a phosphonic acid, $RPO(OH)_2$, although normal phosphonic acids are dibasic. The ready formation of (b) would indicate the presence of a secondary OH group in (a), but (a) is unchanged by boiling Al_2O_3 , CrO_3 or cold dil. $KMnO_4$, so that the presence of an OH group (except possibly tertiary) is improbable. Neither could any ketone reactions be obtained. Contrary to (b), (a) reacts as a satd. compd.; the Na salt does not decolorize Br H_2O in the cold; on heating there is slow reaction and some unchanged (a) crystals out. The change from an open-chain aldehyde to a cyclic secondary alc., however, seems to be peculiar to citronellal and the fact might probably be taken advantage of to detect citronellal in oils in the presence of other aldehydes. Applying the P_2O_5 reaction to natural lemon oil and the com. concd. oil, no evidence of the formation of (a) was obtained, so that the conclusion seems warranted that the citronellal content of lemon oil is quant. insignificant.

CHAS. A. ROUVILLER.

2-Phenylquinoline-4-carboxylic acid (atophan) and its oxidation products. RUDOLF BOEHM AND KONRAD BOURNOT. Univ. Leipzig. *Ber.* 48, 1570-4 (1915).—The pure atophan (a), needles from MeOH, m. $212-3^{\circ}$, is sol. in 20, 25, 35 and 250 parts of boiling EtOH, MeOH, Me_2CO and C_6H_6 , resp. The alkali salts are colorless and cryst.; the Na salt is little sol. in 15% NaOH, the acid dissolving in NaOH of that concn. but solidifying in a few sec. to a thick magma of fine needles. A mixt. of hot solns. of 10 g. (a), 20 cc. of 15% KOH and 39 g. $KMnO_4$ in 800 parts of H_2O is heated to boiling and steam distd.; when the oxidation is complete (30-40 min.) the soln. is cooled, filtered from the MnO_2 , made faintly acid with dil. H_2SO_4 , evapd. to incipient crystn. of K_2SO_4 , drained, treated with dil. H_2SO_4 as long as a white ppt. (b) is formed, boiled up once with alc., crystd. twice from the least possible amt. of boiling H_2O , decompd. with hot HCl and extd. with Et_2O ; this gives 6.5 g. of α -phenylpyridine- α',β',γ -tricarboxylic acid, sepg. on long standing of a hot supersatd. soln. in air-tight vessels in prisms with 1 H_2O , decomp. $183-5^{\circ}$ (loss of CO_2), m. 239° , sublimes partially undecompd. at higher temps., gives a red color in H_2O with $FeSO_4$. The neutral *potassium* and *sodium*, the *calcium* and *cadmium* salts are sol. in H_2O , the *barium* and *silver* salts almost insol. *Acid potassium salt*, $C_{14}H_7O_4N.C_{14}H_7O_4NK.3.5H_2O$, forms the ppt. (b) above; it can also be obtained by treating 1 g. of the acid in 30 g. H_2O with 0.3285 g. $KHCO_3$ in 10 g. H_2O , sepg. at once in gleaming crystals and, on recrystn. from boiling H_2O , in very slender tables and prisms. α -Phenylpyridine- β',γ -dicarboxylic acid, obtained in 33% yield from the tri- CO_2H acid boiled 5 hrs. with 20 parts AcOH containing 10% of Ac_2O , somewhat yellowish silky needles and whetstone-shaped prisms from boiling H_2O , gives no color with aq. $FeSO_4$, forms easily sol. alkali and alk. earth salts and difficultly sol. cryst. Ca, Cd and *silver* salts. *Acid potassium salt*, $C_{14}H_7O_4N.C_{14}H_7O_4NK$, obtained by shaking the finely powdered acid and the calcd. amt. of $^{100}CO_2$ 1 hr. in 50 parts H_2O , warming gently until soln. is complete and allowing to

stand over H_2SO_4 , needles, decomp. 279° (loss of CO_2). *Dimethyl ester*, from the acid in MeOH treated 6 hrs. with HCl, evapd. *in vacuo*, dissolved in CHCl_3 , shaken with Na_2CO_3 , then with ignited Na_2SO_4 , platelets, m. 74° . The steam distn. during the oxidation of (a) and extrn. of the MnO_2 with Et_2O yields 1 g. of $\text{PhC:N.C}_6\text{H}_4\text{O}$ (Laden-

burg, Ber. 9, 1526(1876)), needles and tables from alc., m. 103° .

C. A. R.

Aromatic-chain-shaped aliphatic indigoid dyes. W. HERZOG AND AD. JOLLES. Vienna. Ber. 48, 1574-8(1915).—*2-Thionaphthene-3-pentanonindigo* (a), $\text{CO.C}_6\text{H}_4\text{S.C:}$ -

C_6Ac , obtained in 1.5 g. yield from 2.39 g. thionaphthenequinonanilide and 1 g. CH_3Ac , heated a short time in about 10 g. Ac_2O under a reflux condenser, reddish yellow, silky, felted needles from ligroin or MeOH, m. $142-3^\circ$, sol. in cold concd. and fuming H_2SO_4 with blue-violet color and repptd. by H_2O in flocks, sol. in hot fuming acid with dirty green color and formation of a sol. SO_3H acid, only slightly sol. in soda and dil. NaOH in the cold, but sol. on addition of hyposulfite and gentle warming with formation of the light yellow leuco compd. *2-Indole-3-pentanonindigo* (b), similarly obtained in 62% yield from α -isatinanilide and CH_3Ac , cinnabar-red needles from AmOH or AmOAc, m. about 200° (decompn.), sublimes with partial decompn. and formation of yellow-red fumes, sol. in concd. and fuming H_2SO_4 with deep wine-red color changing to dirty green on warming, only slightly sol. in cold dil. alkalis and in soda and decompd. by warming with somewhat more concd. alkalis, gives an orange-yellow hyposulfite vat. A very dil. CHCl_3 soln. of (a) shows absorption beginning at $507\mu\mu$, increasing to $485\mu\mu$ and continuing const. towards the violet; in a 0.2% soln. absorption begins at $540\mu\mu$ and from $528\mu\mu$ all light is absorbed. In a very dil. soln. of (b), absorption begins at $541.9\mu\mu$ with a max. at $478\mu\mu$ and weaker absorption up to about $442\mu\mu$; in 0.2% soln., the absorption begins at $583\mu\mu$ and is complete from $571.5\mu\mu$ on. *2-Indolebenzoylpropanindigo*, from α -isatinanilide and AcCH_2Bz , fiery red needles from alc., m. $180-1^\circ$, sol. in concd. and fuming H_2SO_4 with dirty violet color changing, even in the cold, to a blue-green, H_2O pptg. a SO_3H acid as a brown powder; heating changes the H_2SO_4 soln. to violet; the dye forms a yellow brown hyposulfite vat. C. A. R.

m-Aminophenylarsonic acids and their reduction products. HUGO BAUER. Georg-Speyer-Haus, Frankfurt a/M. Ber. 48, 1579-83(1915); cf. C. A. 9, 1778.—Heating free $m\text{-H}_2\text{NC}_6\text{H}_4\text{OH}$ on the H_2O bath with H_2AsO_4 results in oxidation and formation of dark substances from which no arsonic acid could be obtained. With the Ac deriv., the Ac group is at once split off. When, however, 90 g. *carbethoxy-m-aminophenol*, m. 97° , which is obtained in 85 g. yield from 109 g. $\text{H}_2\text{NC}_6\text{H}_4\text{OH}$ in 750 cc. hot AcOEt treated with 60 cc. ClCO_2Et , is heated 1 week on the H_2O bath with 100 g. of H_2AsO_4 (75°Bé.), the resulting solid rubbed with H_2O and washed free from H_2AsO_4 , dissolved in NH_4OH , satd. with NH_3 gas, the NH_4 salt dissolved in H_2O and treated with acid, there is obtained *2-hydroxy-4-[carbethoxyamino]phenylarsonic acid* (a), $\text{HO}(\text{EtO}_2\text{CNH})\text{-C}_6\text{H}_3\text{AsO}_3\text{H}_2$, decomp. 213° ; 15 g. boiled 2 hrs. with 30 cc. of 10 N NaOH and 60 cc. of H_2O and then treated with 150 cc. of 2 N H_2SO_4 gives 9 g. of the *4-amino acid*, m. 173° ; 4.66 g. of this in 20 cc. of HCl (d. 1.19) dropped into 10 g. SnCl_2 , 10 cc. HCl (d. 1.19), 20 cc. AcOH and 1 cc. HI (d. 1.7) at -5° , filtered in CO_2 , and washed with AcOH and Et_2O , yields 3.9 g. of *2,2'-dihydroxy-4,4'-diaminoarsenobenzene hydrochloride* (b), light yellow ppt.; its *dicarboxy derivative*, light yellow ppt., sol. in NaOH with yellow color, is obtained from 3 g. (a) in 15 cc. MeOH stirred 0.5 hr. with 50 cc. H_3PO_4 and 1 g. KI. *2-Hydroxy-4-nitrophenylarsonic acid* is obtained in 72 g. yield from 77 g. $3,6\text{-O}_2\text{N}(\text{H}_2\text{N})\text{-C}_6\text{H}_3\text{OH}$ in 170 cc. HCl (d. 1.12) and 350 cc. H_2O in ice diazotized with 36 g. NaNO_2 , stirred with an aq. soln. of 65 g. Na_3AsO_3 , made alk. with 2 N NaOH, then acid with HCl, filtered, made alk. with NH_3 , heated to boiling with magnesia mixt., the resulting

yellow Mg salt filtered, rubbed up with H_2O , dissolved in HCl and rubbed; it begins to soften 212° , and decomp. about 250° ; when 6.6 g. is boiled 2 hrs. with 40 g. Fe filings, 40 cc. H_2O and 1.6 cc. AcOH, made alk. with NaOH, filtered, the residue extd. several times with boiling alk. H_2O , the filtrates stirred up with 15 cc. $ClCO_2Et$, made acid with HCl, treated with NH_3 and magnesia mixt., heated to boiling, the Mg salt filtered off, dissolved in a little dil. HCl and pptd. by further addition of HCl, (a) is obtained, thus proving that it has the structure given above. (b) has considerably less therapeutic value than its isomer, salvarsan.

CHAS. A. ROUILLER.

3-Methylcoumarin. H. SIMONIS. Berlin. *Ber.* 48, 1583-5 (1915).—Although, in agreement with v. Pechmann (*Ber.* 17, 929 (1884)), no weighable amt. of coumarin was obtained from PhOH, malic acid and *concd.* H_2SO_4 , 1 g. can be obtained from 23 g. PhOH, 37 g. malic acid and 100 g. of 73% H_2SO_4 (cf. *C. A.* 2, 1703); the H_2SO_4 can also be dild. with alc. instead of H_2O . Similarly, when 16 g. α -methylmalic acid in 10-5 g. cold alc. are treated drop by drop with 20-5 g. cold H_2SO_4 , allowed to stand 24 hrs., poured into ice H_2O and extd. with Et_2O , there is obtained 3-methylcoumarin; yield, 1.5 g. from 80 g. of the malic acid.

CHAS. A. ROUILLER.

Chief constituent of Japanese lac. V. Constitution of hydrourushiol. RIKO MAJIMA. *Ber.* 48, 1593-7 (1915); cf. *C. A.* 8, 933.—Brief summary of the exptl. evidence given in the 3 following abstrs., whereby it is shown that hydrourushiol is 1-pentadecyl-2,3-dihydroxybenzene, instead of the 3,4-(HO) $_2$ compd. as previously supposed; the latter is now designated isohydrourushiol by M.

CHAS. A. ROUILLER.

Isohydrourushiol and its lower homolog. RIKO MAJIMA AND IKUYA NAKAMURA. *Ber.* 48, 1597-603 (1915); cf. preceding abstr.—Inasmuch as the 3 compds. 3,4-(MeO) $_2$ - C_6H_3R ($R = C_{14}H_{29}$, $C_{15}H_{31}$ and $C_{16}H_{33}$) previously synthesized proved not to be identical with hydrourushiol di-Me ether, they and the corresponding phenols have again been made by different methods. *Isohydrourushiol* (a), 3,4-(HO) $_2$ - $C_6H_3(CH_2)_{14}Me$, and its lower homolog melt much higher than hydrourushiol (b), and the former give a permanent green color with alc. $FeCl_3$ while (b) becomes only temporarily green, then soon blackens and gradually deposits a black ppt. With alc. alkali, (a) becomes blue, then red, and its di-Me ether on nitration yields only a mono- NO_2 deriv., while (b) with alc. alkali becomes green, then red and finally brownish red, and its ether gives a mono- and a di- NO_2 deriv. (a) is prepd. by heating 8 g. each of *o*- $C_6H_4(OH)_2$ and $Me(CH_2)_{11}CO_2H$ and 20 g. $SnCl_4$ 2 hrs. on the H_2O bath, cooling, treating with HCl, washing the ppt. with H_2O , drying, washing with petr. ether, crystg. the ketone, m. 100° , from xylene (yield, 4.6 g.), and reducing the latter by Clemmensen's method (2.5 g. ketone heated 10 hrs. on the sand bath with 35 g. amalgamated Zn, 1 part *concd.* HCl and 2 parts H_2O ; yield, nearly quant.); it seps. from xylene in leaflets, m. 91° , and gives palmitic acid with $KMnO_4$ in Me_2CO . The di-Me ether (c), long flat leaflets from alc., m. $50-1^\circ$, is obtained by reduction with Zn-Hg of the ketone $(MeO)_2C_6H_3(CH_2)_{14}CO-(CH_2)_{11}Me$, m. $62-2.5^\circ$, which in turn is prepd. by reduction in Et_2O with Pt black and H of the compound $(MeO)_2C_6H_3CH:CHCO(CH_2)_{11}Me$, yellowish flat prisms from alc., m. $67-8^\circ$, obtained in 2.3 g. yield from 2 g. each of methylvanillin and $Me(CH_2)_{11}Ac$ and 2 cc. of 10% NaOH allowed to stand 2 weeks in 100 cc. alc. When (c) is heated 2 hrs. at $180-90^\circ$ with 5 parts of HBr (d. 1.78), extd. with Et_2O , washed with H_2O , the Et_2O evapd., the residue dissolved in alc. and treated with alc. $Pb(OAc)_2$, the well-washed ppt. decompd. with H_2SO_4 and the product distd. under 0.5 mm. and crystd. from xylene, (a) is obtained. (c) in 20 parts AcOH warmed a short time with 6 parts of HNO_3 (d. 1.52) dild. with AcOH gives a *mononitro derivative*, $C_{22}H_{41}O_4N$, yellowish needles, m. $70-1^\circ$, cannot be converted into a di- NO_2 compd. 3,4-Dihydroxy-1-tetradecylbenzene (d), m. 84° , gives $Me(CH_2)_{11}CO_2H$ with $KMnO_4$ in Me_2CO , is obtained by heating *o*- $C_6H_4(OH)_2$ and myristic acid with $SnCl_4$ on the H_2O bath and reducing

with Zn-Hg the resulting ketone, m. 103° . The compound $(\text{MeO})_2\text{C}_6\text{H}_4\text{CH}:\text{CHCO}-(\text{CH}_2)_{10}\text{Me}$, m. $67-7.5^{\circ}$, from methylvanillin, $\text{Me}(\text{CH}_2)_{10}\text{Ac}$ and NaOH in alc., is reduced by Pt and H to the satd. ketone, m. $54-6^{\circ}$, which in turn with Zn-Hg gives the di-Me ether, m. $47-8^{\circ}$, of (d); this ether could not be converted into a labile form, m. $37-8.5^{\circ}$, as claimed by Johnson and Kohmann (*C. A.* 8, 3794); with HBr it regenerates (d) while with HNO_3 is obtained a mononitro derivative, m. $67-7.5^{\circ}$. The Me undecyl and dodecyl ketones used in the above syntheses were obtained by dry distn. of mixts. of $\text{Ba}(\text{OAc})_2$ with Ba laurate and tridecanate, resp.; a part of the latter ketone was also made as follows: Ethyl undecylacetate, b₁ $145-50^{\circ}$, is obtained in 8.7 g. yield from 8.6 g. $\text{AcCH}_2\text{CO}_2\text{Et}$ allowed to stand 1 day with 1.46 g. Na in 24 cc. alc., then heated 10 hrs. at 120° with 18.8 g. $\text{C}_{11}\text{H}_{23}\text{I}$; 7.7 g. of this, heated 10 hrs. on the H_2O bath with 3.2 g. KOH in 35 cc. alc., yields 7.6 g. of the ketone, m. $33-4^{\circ}$. CHAS. A. ROUILLER.

1-Propyl-2,3-dihydroxybenzene. JUNZO KUROSAWA. *Ber.* 48, 1603-6(1915); cf. preceding abstr.—1-Propyl-2,3-dihydroxybenzene (a) was prepd. in order to obtain a simple substance related to hydrourushiol and to compare its properties with the latter. o-Dihydroeugenol, b_m $144-6^{\circ}$, is obtained in 11 g. yield from 15 g. o-eugenol reduced with Pt black and H; 4 g. of this, heated 3 hrs. at 150° with 20 cc. of 48% HBr, gives 3.2 g. of (a), needles from petr. ether, m. $70-2^{\circ}$, gives with aq. FeCl_3 a brown color gradually becoming black and forms a violet-black ppt., but in alc. is produced a transient green color soon turning black; with aq. alkali is gradually obtained a red color while in alc. there first appears a green color, then brown and finally a brownish red; small amounts on the skin slowly produce inflammation and severe itching. Dimethyl ether (b), b_m $134-7^{\circ}$, is obtained in 10.4 g. yield by heating 16.4 g. o-eugenol and an equiv. amt. of NaOEt in alc. with 12.3 g. Me_2SO_4 2 hrs. on the H_2O bath and reducing with Pt and H the resulting o-eugenol Me ether, b_m $139-46^{\circ}$, which is formed in 12.5 g. yield. Mononitro derivative of (b), from 5.5 g. (b) in 56 cc. cold AcOH treated in the course of 1 hr. with 11 cc. HNO_3 (d. 1.4) in 50 cc. AcOH and allowed to stand 1 hr. in ice, b_m $185-6^{\circ}$, partly crysts. after months in needles, m. 32.5° , of the same compn.; probably a mixt. of isomeric mono- NO_2 compds. is formed; heated a short time with HNO_3 (d. 1.4), it is converted into the dinitro derivative, long yellowish monoclinic tables, m. $91-1.5^{\circ}$, also obtained from 1 g. (b) in 5 cc. AcOH warmed a few min. with 3 cc. of HNO_3 (d. 1.52). 1-Propyl-3,4-dihydroxybenzene and its dimethyl ether, similarly obtained from eugenol, behave entirely like isohydrourushiol; the phenol in alc. with FeCl_3 gives a green color and with alkali first a bluish, then a red color, while in H_2O is obtained a green, then a brown color with FeCl_3 and a red color with alkalies; the ether gives a mono- NO_2 deriv. but so far it has not been possible to make a di- NO_2 compd. CHAS. A. ROUILLER.

Chief constituent of Japanese lac. VI. Synthesis of hydrourushiol. RIKO MAJIMA AND JOSHIHIDE TAHARA. *Ber.* 48, 1606-11(1915); cf. preceding abstrs.—The following synthesis proves the correctness of the conclusion drawn from the work reported in the preceding abstrs. that hydrourushiol (a) is $2,4-(\text{HO})_2\text{C}_6\text{H}_3\text{C}_{11}\text{H}_{23}$. 0.38 g. Na is vigorously shaken in a test tube with a little hot PhMe; the lower part of the tube, containing the finely divided Na, is cut off and introduced into a long glass tube containing 2 cc. of Et_2O ; after the Na has become detached from the piece of test tube, the latter is removed, the lower part of the long tube is cooled with ice and salt, 3 g. $\text{CH}:\text{C}(\text{CH}_3)_2\text{Me}$ is added, the tube is evacuated, sealed, heated 1 hr. at 60° , cooled with ice and opened under N; to its contents is added 3.8 g. $2,3-(\text{MeO})_2\text{C}_6\text{H}_3\text{CH}_2\text{CH}_2\text{COCl}$ in a little Et_2O , the tube is resealed and heated with frequent shaking 2 hrs. at 60° ; the contents are now treated with Et_2O and H_2O , the Et_2O soln. washed with dil. alkali and H_2O , dried with Na_2SO_4 concd. and treated with H and Pt, fresh Pt being occasionally added; in the course of 2 days, 390 cc. H are absorbed, and after filtering and concg.

the Et_2O soln. there is obtained 1.1 g. of *2,3-dimethoxyphenylethyl dodecyl ketone*, flat needles from MeOH , m. $47-9^\circ$; this with Zn-Hg gives a compd. in all respects identical with the di-Me ether of natural (a). In the course of various attempts to synthesize (a) the following new compds. were made: *2,3-Dimethoxyphenylethyl hexadecyl ketone*, from hexadecin heated 2 hrs. with Na at 100° and then treated as above, m. 57° . *o*-Acetyl Eugenol, b₁₅ $146-8^\circ$, from *o*-eugenol and cold Ac_2O with a little H_2SO_4 is ozonized in CHCl_3 at 0° , at once distd. with steam, the residue extd. with Et_2O and the ext. shaken with NaHCO_3 . Although the aldehydic substance in the Et_2O weighed about 8 g., it yielded only 1 g. of *2-acetoxy-3-methoxyphenylacetaldehyde semicarbazone*, m. 179.5° . The NaHCO_3 soln. yields the acid, m. 146° . CHAS. A. ROULLER.

Sulfones of the thiophene series. O. HINSBERG. Freiburg i/Br. *Ber.* 48, 1611-4(1915).—*Thionessol sulfone (tetraphenylthiophene dioxide)*, obtained almost quant. from thionessal (a) in hot AcOH warmed several hrs. on the H_2O bath with 2.5-3.0 mols. of 30% H_2O_2 , intensely yellow prisms, m. 265° , insol. in acids and alkalies, unchanged by boiling with Zn dust and AcOH but converted back into (a) when concd. HCl is added to the reducing mixt., sol. in cold H_2SO_4 without color and turning yellow on warming. It is not identical with the substance $\text{C}_4\text{H}_4\text{SO}_2$ obtained by Lanfry from H_2O_2 and (a) (*C. A.* 5, 3226). *3,4-Diphenylthiophene*, obtained by heating the di- CO_2H acid in 1-2 g. portions in a test tube until the evolution of CO_2 ceases, taking up in CHCl_3 , evapg. and crystg. several times from AcOH and finally from dil. alc., striated prisms from AcOH , m. 114° , sol. in hot H_2SO_4 with intense yellow color changing to blue-green on addition of isatin. With H_2O_2 in AcOH on the H_2O bath it gives the sulfone, purified by warming the recrystd. product with a little Zn dust in AcOH and cautiously adding H_2O to the filtrate; it seps. in faintly yellow, hair-like needles and, on recrystn. from alc. or AcOH , in light yellow prisms, m. 182° . 3-Methylpiazthiole is hardly attacked at all by 30% H_2O_2 in AcOH on the H_2O bath. C. A. ROULLER.

The so-called pentazole compounds of J. Lifschitz. TH. CURTIUS, AUGUST DARAPSKY AND ERNST MÜLLER. Heidelberg and Cologne. *Ber.* 48, 1614-34(1915); cf. L., C. A. 9, 1614.—A repetition of L.'s expts. has shown that all his observations and the theoretical conclusions drawn from them are erroneous and that there is no formation of pentazoles from tetrazole nitrile (a) and $\text{N}_2\text{H}_4\cdot\text{H}_2\text{O}$ (b). Not only can many of the observations he describes be at once classed as impossibilities by one familiar with the reactions of the hydrazine compds., but in all but 1 case he detd. only the N of his compds. and even these detns. are mostly incorrect. When 4.75 g. (a) in 50 cc. alc. are treated at 0° with 5 g. (b) in 10 cc. alc. there is at once formed 3.57 g. of a white ppt., m. turbid about 220° ; the filtrate after 15 min. in the cold deposits 0.26 g. more. If the filtrate is now heated 3 hrs. under a reflux condenser in the H_2O bath, NH_3 is evolved and the mass solidifies to a yellow cryst. magma which, when cooled to 0° , yields 3.42 g. of a substance which does not m. 280° ; 2 hrs. more heating of the mother liquors yields 0.49 g. more and a 3rd heating of 3 hrs. gives 0.11 g. more. The white substance partially dissolves when rubbed with 20 cc. ice H_2O and the soln. in *vacuo* over H_2SO_4 deposits 1.5 g. needles, m. 230° after crystn. from dil. alc., consisting of *dihydrazine bistetrazole*, $(\text{N}_2\text{H}_4\cdot\text{R}-)_2$ ($\text{R} = \text{NH}\cdot\text{N}:\text{N}:\text{N}:\text{C}-$), the formation of which is

doubtless due to the presence in the (a) of bistetrazole which, in the prepn. of (a) from $(\text{CN})_2$ and HN_3 , is formed as a by-product by the addition of HN_3 to the (a); shaken in H_2O with BzH , the needles at once give $(\text{PhCH}:\text{N}-)_2$. The residue insol. in ice H_2O is insol. in boiling H_2O but easily sol. in dil. HCl , the soln. giving with BzH a ppt. insol. in Et_2O ; it is not reddened by nitrite and HCl . The yellow $\frac{1}{2}\%$ warmed 0.5 hr. on the H_2O bath with 5 cc. of (b), evolves NH_3 to an orange-yellow magma of *dihydrazine ditetrazyl-dihydrotetrazine*,

crude salt in 50 cc. H_2O supersatd. with 20 cc. of dil. HCl give a thick yellow mush of the free *ditetrasyldihydrotetrasine* (*d*) (L.'s pentazidoacetic hydrazide), seps. with 2 mols. H_2O which it loses, without decompn., *in vacuo* at 130° (yield, 0.82 g.); the filtrate yields 0.98 g. $\text{N}_2\text{H}_4 \cdot 2\text{HCl}$. Warmed with aq. (*b*) it regenerates the bis- N_2H_4 salt. The latter, boiled with 35% KOH , does not evolve NH_3 , as stated by L., but N_2H_4 and gives the light yellow *dipotassium salt*, $\text{C}_4\text{H}_5\text{N}_{11}\text{K}_2$, of (*d*), which with excess of AcOH in hot H_2O gives back (*d*). Finally, the bis- N_2H_4 salt with molten KOH yields a substance giving with HNO_3 and AgNO_3 a white Ag salt which deflagrates on heating (probably Ag tetrazole). Towards cold dil. acids, (*d*) is stable, but when boiled 2 hrs. under a reflux with a mixt. of 2 vols. concd. HCl and 1 vol. H_2O it is quant. decompd. into 2 mols. N_2H_4 and 2 mols. RCO_2H . From 2.2 g. (*d*) suspended in 22 cc. H_2O and dissolved by adding soda until just alk., then treated ice-cold with 2.76 g. NaNO_2 in 5 cc. H_2O , at once acidified with AcOH and allowed to stand in ice is obtained the orange-red *disodium ditetrasyldetrasine*, $\text{C}_4\text{N}_{12}\text{Na}_2 \cdot 2\text{H}_2\text{O}$ (L.'s triazolone), which is not decompd. by AcOH , but with ice-cold

dil. H_2SO_4 it gives the free crimson *ditetrasyldetrasine* (*e*), $\text{RC} \begin{array}{c} \diagup \text{N} \diagdown \\ \diagdown \text{N} \diagup \end{array} \text{N} \text{CR}$ (L.'s iso-

nitrosopentazidoacetic hydrazide), 6-cornered leaflets or large needles from alc.; it is also obtained from (*d*) with CrO_3 in cold dil. H_2SO_4 . When boiled with alc. HCl until the red color changes to red, it loses 0.5 mol. N_2 and gives (*d*) (L. states that isonitrosopentazidoacetic acid is formed, so that this compd. of his and his pentazidoacetic hydrazide are one and the same compd., *vis.* (*d*)). The hydrolysis is explained thus: (*e*) + $2\text{H}_2\text{O} \longrightarrow \text{NH:NH} + \text{RC(OH):NN:C(OH)R} (\longrightarrow \text{RCONHNHCOR})$; (*e*) + $\text{NH:NH} \longrightarrow (\text{d}) + \text{N}_2$. The dihydrazide (RCONH-)₂ which according to this scheme is formed from the 1st mol. of (*e*) has not as yet been isolated. When MeCN is boiled 3.5 days with *anhydrous* $\text{N}_2\text{H}_4 \cdot \text{NH}_3$ is evolved and although on distg. the reaction mixt. under diminished pressure much of the MeCN and N_2H_4 are recovered unchanged, the part which does react gives solely *dimethyldihydrotetrasine* (and not the isomeric *C*-dimethyl-*N*-aminotriazole, as is obtained with $\text{N}_2\text{H}_4 \cdot \text{H}_2\text{O}$; *J. prakt. Chem.* 52, 272(1895)); it seps. from H_2O with 1 mol. of solvent in which it m. 100° ; *anhydrous*, it becomes reddish at 90° , bright red at 110° , colorless at 150° , softens 178° , m. 181° , isomerizing into the triazole; with NaNO_2 and AcOH it gives *dimethyltetrasine*, sublimes without decompn. in needles, m. 74° , sol. in H_2O with yellowish red, in Et_2O with bluish red color, is very volatile even at room temp., and is reduced by H_2S in H_2O to the dihydro compd.

CHAS. A. ROUVILLER.

Arseno-metallic compounds. P. EHRLICH AND P. KARRER. Georg-Speyer-Haus, Frankfurt a/M. *Ber.* 48, 1634-44(1915); cf. *C. A.* 8, 2034, 2222.—What is stated below for $[\text{3,4-H}_2\text{N}(\text{HO})\text{C}_6\text{H}_4\text{As}]_2$ (*a*) holds for all other arseno compds. (*a*) can

add a max. of 2 mols. of a metallic salt to form compds. of the type $\begin{bmatrix} \text{RAs} \dots \text{M} \\ \parallel \\ \text{RAs} \dots \text{M} \end{bmatrix} \text{X}$.

Since, in general, these addition compds. have the same solubilities as the arseno compds. from which they are derived, their comp., except in the case of the CuCl_2 compds., could not be detd. by analysis. Into 100 g. (*a*) $\cdot 2\text{HCl}$ in 1600 cc. MeOH and 16 cc. satd. alc. HCl is introduced with turbinig 35.8 g. $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ in 400 cc. alc., then the liquid is poured into 8 l. Et_2O , the brick-red ppt. sucked off, washed with Et_2O and dried in a high vacuum. The whole operation is best carried out in a N or CO_2 atm.

This *copper salvarsan* (b) is a red to orange-yellow powder, moderately sol. in H_2O , more easily in glycerol and glycol, easily in 2 *N* NaOH without sepn. of $Cu(OH)_2$ until the soln. is heated, when the salt gradually decomp. It has the compn. (a).2HCl.CuCl₂. If twice as much CuCl₂ is used, the resulting compound, which has properties very similar to the above, has the compn. (a).2HCl.2CuCl₂. When 10 g. 3,4- $H_2N(HO)C_6H_4AsO_2H_2$ in 100 cc. H_2O and 43 cc. of 2 *N* NaOH and 3.64 g. $CuCl_2 \cdot 2H_2O$ are turbined 2 hrs. at 50° with 100 g. $Na_2S_2O_4$ and 43 cc. more of NaOH, the tendency of the (a) formed to add the CuCl₂ is so great that the latter is not reduced and there is obtained a substance sepg. in yellow-brown flocks, very easily sol. in dil. HCl and NaOH and containing As and Cu in the atomic ratios 1:1. When 1 g. (a).2HCl in 30 cc. MeOH is treated with 0.716 g. $AgNO_3$ in MeOH and the red-brown liquid is poured into Et_2O there is formed a *silver nitrate salt*, (a).2HCl.2 $AgNO_3$, brown flocculent ppt. easily sol. in H_2O , NaOH, MeOH, etc.; the aq. soln. gives with NaCl a brown-yellow ppt. moderately sol. in H_2O , little sol. in NaCl soln. and which is probably the *silver chloride salt*, (a).2HCl.AgCl. With 0.5 as much $AgNO_3$ is obtained a compound (a).2HCl. $AgNO_2$. If 1 g. (a).2HCl in 20 cc. MeOH is treated with 0.61 g. $HgCl_2$ in MeOH and a few drops of alc. HCl, the light yellow soln. becomes orange and in a few moments the *addition product* begins to sep. as a yellow granular powder, decompd. by H_2O , especially on warming, more quickly by NaOH, with deposition of Hg, insol. in NaCl and KI. *Mercuric iodide compound*, yellow-red, much more stable than the chloride. *Gold chloride compounds*, from 1.5 g. (a).2HCl and 1 and 2 g., resp., of $AuCl_3$ in MeOH, with subsequent addition of Et_2O , brown-yellow powders easily sol. in NaOH. If (a).2HCl in 500 parts H_2O is titrated with 1% $AuCl_3$, the soln. becomes brown-red until 2 mols. $AuCl_3$ have been added; further addition of $AuCl_3$ produces a pptn. of metallic Au until 3 mols. of $AuCl_3$ in all have been added and the (a) is oxidized to the arsonic acid. *Platinic chloride compound*, formed instantly from the components in MeOH, brown powder. From 3 g. $PhAs:AsPh$ in C_6H_5N treated with 1.7 g. $AgNO_3$ in concd. H_2O soln. and then with alc.- Et_2O is obtained a black insol. *addition product*. The *copper compound* is easily obtained as a red-brown, insol., amorphous powder by reducing a mixt. of 4 g. $PhAsO_2H_2$ and 3.4 g. $CuCl_2 \cdot 2H_2O$ with H_3PO_2 . The pharmacological action of these complexes is in many cases markedly more pronounced than that of (a) itself. Thus, in the case of (b), with a toxicity of about 1/600 g. per 20 g. mouse wt. 1/40,000 g. suffices to cure a mouse injected with *Trypanosoma prucei*.

CHAS. A. ROUILLER.

Polycinnamic esters (continuation). C. LIEBERMANN, G. MÜHLE AND M. KARDOS. Kaiser-Wilhelm-Inst., Berlin-Dahlem. *Ber.* 48, 1645-8(1915); cf. *C. A.* 7, 2554.—The allyl cinnamate polymerized in direct sunlight has been further studied. After being obtained as a pure white flocculent ppt. by pouring into much MeOH, it must be washed by shaking with fresh MeOH several days to remove all of the monomol. ester until the MeOH leaves no residue on evapn. The polymerized ester then forms a white, friable powder, easily sol. in cold $CHCl_3$, gelatinized by cold C_6H_6 but quite sol. on heating; long continued boiling with 20% alc. KOH fails to sapon. it; an attempt to dry it at 110° resulted in making about 25% of it insol. in $CHCl_3$, and at a higher temp. the change in this direction is still greater (the max. being at 138-40°; if exhaustively extd. with $CHCl_3$ and dried at 110° it then gives a C value 2% too low, either because it is so difficultly combustible or for a more deep-seated reason. Contrary to the insol. heat-polymerized form B previously described the new insol. form can no more be sapond. than the sol. form from which it is obtained. In view of the difficulty of completely washing out the monomol. form with MeOH, the light-polymerized Et ester, previously described as dissolving only in traces in org. solvents, has been subjected to renewed purification. After carefully rubbing several times with cold $CHCl_3$,

it was shaken a long time on the machine, then boiled twice for 0.5 hr. periods with CHCl_3 under a reflux; the individual fractions, after filtering and concg. to a small vol., gave with petr. ether white, finely pulverulent ppts. diminishing in amt. and finally disappearing in the last extns.; in all, about 5% of a CHCl_3 -sol. form was thus obtained; the only difference in the 2 forms, however, is in the solubility, for the sol. form can not be sapond. any more than the insol. form. The light-polymerized Me ester, thus far considered as insol., is easily sol. in cold CHCl_3 , petr. ether pptg. from the concd. soln. a fine white powder, m. above 300° , which loses none of its solubility after months in a vacuum desiccator; long heating at 140° converts it into a CHCl_3 -insol. form. The light-polymerized PhCH_3 and octyl esters are not rendered insol. in cold CHCl_3 by long heating at 140° .

CHAS. A. ROULLER.

Action of oxalyl chloride on bianthryl. C. LIEBERMANN, M. KARDOS AND G. MÜHLE. Kaiser-Wilhelm-Inst., Berlin-Dahlem. *Ber.* 48, 1648-53(1915); cf. *C. A.* 7, 3323.—In a flask provided with a stirrer, Hg valve and condenser, 5 g. finely powdered bianthryl, and 20 g. $(\text{COCl})_2$ in 35 cc. cold CS_2 are treated with 4 g. AlCl_3 and, after 2 hrs. stirring, with 3.5 g. more AlCl_3 and 35 cc. CS_2 , stirred a long time, allowed to stand overnight, decompd. with ice, freed of CS_2 by distn., treated with boiling dil. HCl , the brown-red mass boiled out with 400 cc. of 5% soda, then extd. hot twice with 200 cc. concd. NaHSO_3 and 2 l. H_2O , filtered hot, pptd. with H_2SO_4 , dried, exhausted with C_6H_6 and extd. with boiling soda. There is thus obtained 3.1 g. *bisanthrylacediquinone* (10,10'-bisaceanthrenequinone) (I), which, purified through its NaHSO_3 compd.,

seps. from C_6H_6 as a highly red cryst. powder, m. above 350° , but slightly sol. in org. solvents (except CHCl_3), sol. in H_2SO_4 with pure green color; it is not a vat dye; it yields a yellow *oxime* and a dark red *phenylhydrazone*. The soda exts. obtained in its prepn. yield on acidification 1.5 g. of a yellow-brown ppt. which is treated, while still moist, several times with a hot aq. suspension of CaCO_3 ; the resulting sol. Ca salt on acidification yields a ppt. of *bisanthryltetracarboxylic acid* (II), fine orange powder from AcOH , loses 1 mol. H_2O at 160° with formation of a monoanhydride, forms no fluorescein when fused with $m\text{-C}_6\text{H}_4(\text{OH})_2$ (without ZnCl_2); *calcium salt*, light yellow flocks from alc.- H_2O . The treatment with CaCO_3 also yields a mixt. of 2 insol. Ca salts; when the mixt. of the corresponding acids is extd. with boiling AcOH , *bisanthrylacediquinonemonocarboxylic acid* (III) dissolves and on cooling seps. as a brick-red powder. The residue insol. in AcOH is dissolved in $\text{C}_6\text{H}_5\text{N}$; dil. HCl ppts. from this soln. *bisanthrylacediquinonemonocarboxylic acid*, light brown flocks contracting on drying to a chocolate-brown powder.

CHAS. A. ROULLER.

Azafrin. III. C. LIEBERMANN AND G. MÜHLE. Kaiser-Wilhelm-Inst., Berlin-Dahlem. *Ber.* 48, 1653-60(1915); cf. *C. A.* 7, 2946.—The compn. of the colored compds. which azafrin (a) yields with strong acids and one of which (perchlorate) is cryst., together with the analyses of (a) itself and its Me deriv., led to the adoption of the formula $\text{C}_{21}\text{H}_{15}\text{O}_5$ for (a). This is not confirmed definitely by the present work, which was

interrupted by the death of L. In addition to the compds. with acids previously described, 1 g. (a) boiled 5 min. with 30 cc. HCO_2H yields a deep violet soln. which, when filtered and evapd. *in vacuo* over KOH, leaves the *formate*, (a). HCO_2H , as green-black crusts assuming a cantharides luster on rubbing. A soln. of (a) in $\text{AcOH-HCO}_2\text{H}$ retains its deep violet color for months; on filtering and pptg. with satd. NaCl the HCO_2H compd. seps. in flocks with cantharides luster sol. in alc. with pure violet color. Evapn. of the soln. leaves crusts with metallic luster, blue by transmitted light, which contain considerable NaCl (4.8% Na). The acid-free form of (a) corresponding to the colored salts has not been isolated pure. Alkalies under the proper conditions, to be sure, give a Cl-free colorless substance spontaneously forming colored salts with dil. acids, but it could not be obtained in a state fit for analysis. However, the base corresponding to the colored salts is quite different from (a) itself; perhaps it is related to a rearrangement *product*, light yellow amorphous powder of the same comp. as (a), which is obtained by long boiling of (a) with AcOH or still better with PhNMe_2 and is purified by pptg. from dil. KOH with dil. HCl. From 0.4 g. (a) in 125 cc. C_6H_6 and 0.2 g. I in 10 cc. C_6H_6 allowed to stand 24 hrs. is obtained a heavy green-black powder segg. from CHCl_3 in almost black, short, thick columns having a comp. (C 41.61-41.57, H 5.00-4.80, I 46.62-46.42%) intermediate between that calcd. for $\text{C}_{11}\text{H}_{10}\text{O}_4\text{I}_2$ and $\text{C}_8\text{H}_6\text{O}_4\text{I}_2$. Characteristic of this *iodide* is the royal blue color of its CHCl_3 soln., which persists even on long boiling; in alc. it dissolves with violet color completely destroyed by excess of SO_2 but reappearing when the SO_2 is boiled out; alc. SO_2 extraordinarily accelerates its soln. in alc. and C_6H_6 ; it m. 145° (decompn.), gives with alc. KOH a colorless K salt, decompd. by acids with regeneration of the original violet color and production of an intense CHI_3 odor; CHI_3 is also formed by rubbing with aq. KOH; addition of H_2O , filtration and acidification with dil. H_2SO_4 gives a deep violet which, after pptn. from CHCl_3 with ligroin, contains only 7.8% I. The compd. is not identical with the HI salt previously described. All attempts to prep. a similar iodide from bixin failed. From 1.5 g. (a) in 50 cc. AcOH and 0.3 g. Pt sponge added in 2 portions, shaken 10 hrs. with H under 1 m. H_2O pressure until the yellow-red soln. is decolorized, is obtained an *oil*, with 74.11% C, 11.33% H, mol. wt. in Et_2O 465, corresponding approx. to $\text{C}_{21}\text{H}_{14}\text{O}_6$ or $\text{C}_{21}\text{H}_{16}\text{O}_6$, easily sol. in org. solvents (except ligroin) and dil. aq. alkalies; more concd. alkalies produce a voluminous white ppt.; moistening with H_2SO_4 blackens it; on attempting to distil it, it b. $220-400^\circ$, the first fractions being mobile but increasing in viscosity with the temp. and finally carbonizing; the distillate has a very strong peppermint odor. From methylazarin in alc. reduced with aq. PdCl_2 , gum arabic and H is obtained an odorless, colorless, viscous *oil*, $\text{C}_{20}\text{H}_{18}\text{O}_6$ or $\text{C}_{20}\text{H}_{20}\text{O}_6$ (found, C 73.86, H 11.26%, mol. wt. in Et_2O 506), insol. in dil. alkalies. Bixin and methylbixin under the same conditions give colorless, viscous, odorless oils, easily sol. in dil. KOH, turned brown or black by H_2SO_4 . CHAS. A. ROUILLER.

Construction with theoretical atoms of the systems of growth of the organic compounds of carbon and hydrogen (CREHORE) 2. Some new rare earth compounds (GRANT) 6. Some new indicators (LUBS) 11B. Detection of halogen in organic substances (KUNZ-KRAUSE) 7.

II. BIOLOGICAL CHEMISTRY.

WILLIAM J. GIES, EDGAR G. MILLER, JR., PAUL E. HOWE.

A. GENERAL.

FRANK P. UNDERHILL.

The disturbing influence of some substances of physiological importance on the color reaction between iodine and starch. A. CLEMENTI. Univ. Rome. *Arch.*

farm. sper. 20, 258-68(1915).—Iodized starch paste is decolorized not only by egg albumen, but also by the most widely different types of proteins. Of the amino acids tested, tyrosine was the only one that possessed this property. Furfural decolorizes the starch iodide, while epinephrine instantly changes the color from blue to rose.

A. W. DOX.

Effect of sodium chloride upon the action of invertase. H. A. FALES AND J. M. NELSON. *J. Am. Chem. Soc.* 37, 2769-86(1915).—The relationship between the activity of invertase and the H-ion concn., working at $37 \pm 0.01^\circ$ with 100 cc. of soln. containing 0.500 g. sugar, enough HCl to give the necessary H-ion concn. and 1 cc. of a stock invertase soln. prepd. by N. and Born's method and containing 7 g. invertase per l. (cf. *C. A.* 8, 1435), was found to be as follows: activity, 0, 75, 85, 94, 51, 33, 26; for p_H 1.4, 3.1, 3.3, 4.5, 6.0, 6.3, 6.5, resp., the activity values being $k \times 10^4$, where $k = (1/\theta) \log_{10} a/(a-x)$. The activity was then measured over the same range of H-ion concns. in the presence of 0.1, 0.5 and 2 M NaCl. The effect of NaCl is twofold: it causes an increase in the H-ion concn. when the concn. of the HCl is greater than 0.0001 M, and a decrease in the activity of the invertase for equal H-ion concns., this decrease in activity being least at the optimum H-ion concn. and increasing on both sides of this optimum, so that the use of buffers in large concn. for regulating p_H introduces more or less of an error if it is desired to get the max. activity of invertase corresponding to a given H-ion concn. The H-ion concns. were detd. by the e. m. f. and colorimetric methods, the amt. of sugar inverted by a modified Defren method. C. A. R.

B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

An improved respiration calorimeter for use in experiments with man. C. F. LANGWORTHY AND R. D. MILNER. U. S. Dept. Agr. *J. Agr. Research* 5, 299-348 (1915).—A detailed treatment which does not admit of brief abstracting. A bibliography of 19 titles is appended.

W. H. FRY.

Some new indicators for the colorimetric determination of hydrogen-ion concentration. HERBERT A. LUBS AND WILLIAM M. CLARK. Washington, D. C. *J. Wash. Acad. Sci.* 5, 609-17(1915).—The following new indicators of the methyl red type were prepared: monoethyl red (color changes between the H-ion exponents 4.25 and 6.00), diethyl red (4.50 to 6.50), monopropyl red (4.25 to 6.25), dipropyl red (4.50 to 6.50). The following previously known indicators were studied: monomethyl red (4.25 to 6.00), α -naphthylamine red (not promising), dimethyl- α -naphthylamine red (5.00 to 6.75), diphenylamine red (4.25 to 5.50). The following new indicators of the sulfonephthalein type were prepared by an improved (described) method: thymolsulfonephthalein (useful between 8.00 and 9.50), α -naphtholsulfonephthalein (7.50 to 9.00), bromothymolsulfonephthalein (6.00 to 7.25). The salt and protein errors and biochem. applicability are being investigated.

L. J. GILLESPIE.

Picramic acid as reagent for albuminous substances. I. I. OSTROMUISLENSKII. *J. Russ. Phys. Chem. Soc.* 47, 317-8(1915).—With peptone, albumose, proteins, egg albumen and both the sol. and the insol. globulins of horse serum picramic acid in aq. soln. or aq. emulsion gives an intense dark red color. The liquid to be tested must be free of alkali or salts whose acids are displaced by this reagent. H. M. GORDIN.

Use of trichloroacetic acid as a protein precipitant. I. GREENWALD. *J. Am. Chem. Soc.* 37, 2604-5(1915).—G. makes no claim to have discovered $\text{CCl}_3\text{CO}_2\text{H}$ as a reagent for the removal of blood proteins, and the use of the phrase "G.'s reagent" (Graves and Kober, *C. A.* 9, 2916) is without justification. CHAS. A. ROULLER.

Icterus following ingestion of picric acid. CH. O. GUILLAUMIN. *J. pharm. chim.* 12, 145-52(1915).—The voluntary ingestion of picric acid by men wishing to escape

army service (said to be 0.2 g. a few hrs. before presentation) is difficult to recognize, as the pigments of urine give color tests similar to those of picric acid. The latter is not extd. by Et_2O from an aq. soln. of 0.02 : 1000, unless much HCl (at least 10 g. per l. for complete extn.) is added. 250 cc. of urine + 10% HCl are extd. 2-3 times by 50 cc. Et_2O . Remove the clear liquid from the emulsion, to the latter add 5-10 cc. EtOH , mix, allow to stand. Unite the Et_2O - EtOH liquids, shake these with anhydrous Na_2SO_4 , filter through cotton, evap. to dryness on water bath, take up with 3-4 cc. H_2O , filter if necessary, wash with 3-4 cc. of H_2O . A nearly pure yellow soln. of picric acid results. The mode of extn. from blood is also given. With 6-10 cc. of soln. perform these identity tests: (1) Dip white wool into the warmed liquid for 3 min., then rinse with H_2O . (2) Boil part of this wool with 3 cc. H_2O and 4 drops of 10% KCN . The wool slowly dissolves and the liquid turns brownish rose to dark red (isopurpurate test). The remaining wool, sepd. and washed, is finally pale rose-red. (3) Formation of picramic acid (Isnard, *C. A.* 8, 3191). (4) Formation of Cu picrate, then isopurpurate: Take 4-5 cc. picric soln., add 1 cc. of a mixt. of $\text{CuSO}_4 \cdot 10\text{H}_2\text{O}$ 100, NH_4OH 40. A yellow cryst. ppt. forms, at once in concd. solns., after some min. in 0.10 : 1000, after some hrs. in 0.05 : 1000. To change this ppt. to isopurpurate, add 3 cc. of H_2O , 5-10 drops of KCN and boil. (5) Pptn. by methylene blue: Mix. 1 cc. of soln. with 1 cc. of 1/200 methylene blue; a blackish blue ppt. forms at once. The 5 methods gave + results with 0.01 g. picric acid per l. of urine when using 250 cc. for a test. The wines dated from the 3rd day following the ingestion of the colorant. S. W.

Separation and determination of peptones (VLÄHUTX) 7.

D. BOTANY.

C. L. ALSBERG.

Synthetic processes in the plant organism. II. Occurrence, significance and formation of sucrose in the germination of *Pisum sativum*. P. BOYSEN-JENSEN. Univ. Copenhagen. *Jahrb. wiss. Botan.* 61, 431-46(1915).—In the germination of the pea, two stages can be distinguished. During the first stage the sucrose originally present before germination is partially utilized for growth and for respiration. The isolated cotyledons show a decrease in the sucrose. In the second stage the sucrose present in the cotyledons is to be regarded as a transitional form of starch, for the following reasons: (1) The concn. of sucrose is greater in the cotyledon than in the embryo. (2) In the isolated cotyledon there is an increase in sucrose while in the isolated embryo there is a decrease. (3) Only insignificant amts. of directly reducing sugars are found in the cotyledons. The formation of sucrose from maltose appears improbable, and the only valid assumption remaining is a hydrolysis of starch to monosaccharides and then a synthesis of these to sucrose. A. W. DOX.

Difference in the composition of the oils of different plants of the same family. G. FIGULÉVSKII. *J. Russ. Phys. Chem. Soc.* 47, 393-405(1915).—From an exam. of numerous plants in respect to their oil content and to the amts. of unsatd. acids in the latter as shown by the I number the following conclusions are drawn: The nature of the oil in a plant depends upon climatic conditions and possibly also upon the conditions of its nutrition, a given plant growing in a cold climate producing acids of a lower degree of satn. and therefore of greater chem. activity than the same plant growing in a warm climate. Cultivated plants growing under more favorable conditions lose the ability to produce acids as unsatd. as those produced by plants in the wild state. While there is a difference in the relative amts. of different acids in different oils, there seems to be little difference in the nature of these acids, these usually being oleic, linoleic and hnolenic.

PHILIP B. HAWK.

NORMAL.

The physiology of the newborn infant; character and amount of the katabolism. FRANCIS G. BENEDICT AND F. G. TALBOT. Carnegie Inst. of Washington, *Pub.* 233(1915).—A systematic research into the metabolism of over 100 newborn infants has resulted in an accumulation of sufficient data for definite conclusions. The infants were for the most part obtained from the Boston Lying-In Hospital and a constant routine was rigidly adhered to in all cases, so that the results are comparable. Several hundred experimental periods were obtained. An analysis of the data for the minimum metabolism periods shows that on the first day of life there are important temp. regulation disturbances which result either in a decreased metabolism, or an increased metabolism when there is an effort on the part of the infant to compensate for the loss of heat. After the second day there is a fair uniformity in the heat production per square meter of body-surface and a remarkable uniformity per square meter of body-surface per unit of length. This constancy is such as to permit the establishment of a factor which indicates that when the square meter of body-surface as computed from the body-weight is divided by the length of the body the metabolism per unit is 12.65 cal. From a study of the effect of temp. changes on the basal metabolism and the amt. of available breast secretion in the first week of life, certain procedures for the conservation of energy and supplemental feeding are suggested. F. G. B.

Importance of lime in the nourishment of man, animals and plants. B. HEINZE. *Naturwissensch.* 3, 536-40(1915).—This paper is based largely upon the researches of Emmerich and Loew. Numerous examples are cited to show the great benefits to be derived from the addition of Ca salts to the daily diet. Every person ought to include in his food 1 to 1½ g. of CaCl₂ or Ca lactate per day. C. G. F.

The nitrogen excretion of the cat during a purine-free and a purine-rich diet. FREDERICK S. HAMMETT. Harvard Med. School. *J. Biol. Chem.* 22, 551-8(1915).—"... With the exception of uric acid, the excretion of the cat of nitrogenous urinary constituents is governed by the same laws as the N excretion of man. . . . On a purine-free diet the % of total N excreted as uric acid is so small as to be of no significance when considering the N of the urine. On a purine-rich diet the increase probably denotes an overburdening of the uricolytic enzymes." I. GREENWALD.

Protein metabolism. J. J. R. MACLEOD. Cleveland. *J. Lab. Clin. Med.* 1, 112-9(1915).—A review of the literature with relation to the circulation and utilization of free amino acids. H. G. W.

ABNORMAL.

Studies in carbohydrate metabolism. X. The influence of hydrazine upon the respiratory quotient and heat production. FRANK P. UNDERHILL AND JOHN R. MURLIN. *J. Biol. Chem.* 22, 499-504(1915); cf. *C. A.* 8, 1812.—The respiratory quotient of hydrazinized dogs indicates that the hypoglucemia and loss of glycogen from the tissues is probably due to an increased combustion of carbohydrate. Dextrose administered to such dogs exerts a specific dynamic action and is oxidized more rapidly than in normal fasting dogs. Hydrazine has no sp. effect upon heat production. I. GREENWALD.

F. PHYSIOLOGY.

ANDREW HUNTER.

The formation of carbohydrates from amino acids circulating in the isolated liver. UGO LOMBROSO AND CAMILLO ARTOM. Univ. Rome. *Arch. farm. sper.* 20, 211-24(1915).—The glycogen of the isolated liver diminishes 20-30% after perfusion with blood for an hour. The diminution is somewhat less when Ringer soln. is used in place of blood. Blood containing amino acids produces a slight increase in glycogen when the

liver is already poor in glycogen. Amino acids dissolved in Ringer soln. produce no such increase. A. W. DOX.

Comparison between the sugar content of the blood under oral and rectal intake of dextrose. G. JAHNSON-BLOHM. *Upsala Läkareförenings Förhandlingar* 20, Nos. 6-7(1915); *J. Am. Med. Assoc.* 65, 1686.—The tests were made on 3 healthy men of 24 and 2 diabetic men of 44 and 73 yrs. Ten g. of dextrose were given by mouth, or 30 g. by rectal injection, all in isotonic salt soln. The sugar content of the blood rose at once in each man after ingestion of dextrose by the mouth; but no increase was perceptible in any when administered by the rectum. The fact of absorption by the rectum was established beyond question, but the cause of its different behavior after absorption is unknown. L. W. RIGGS.

Creatine and creatinine excretion during the puerperium and their relation to the involution of the uterus. ARTHUR MORSE. *Yale Univ. J. Am. Med. Assoc.* 65, 1613-5(1915).—M. reports an extended study of 4 cases in which cesarean section was performed, in 2 instances without the removal of the uterus and 2 with hysterectomy. A lower total N output is observed in case hysterectomy is performed; the higher N output observed when the uterus is left *in situ* is explained by the involution process. A lower creatinine output occurs in case of hysterectomy, and at least 2 g. of this substance excreted during the puerperium arise from involution of the uterus. Creatine in large amts. regularly appears in the urine following childbirth. The creatinuria is independent of both the involution of the uterus and the creatinine metabolism. Two charts and 12 references to recent work are given. L. W. RIGGS.

G. PATHOLOGY.

H. GIDEON WELLS.

The question of the specificity of the Abderhalden reaction. E. HERZFELD. *Deut. med. Wochschr.* 41, 1151-2(1915).—The results of expts. as given in the dissertations of E. Rothlin, Zürich, 1915, and of H. Frey, Zürich, 1915, are given. They contradict directly Abderhalden's theory of specific enzymes. S. AMBERG.

The calcium content of bile and its significance for the formation of gall stones. L. LICHTWITZ AND F. BOCK. *Deut. med. Wochschr.* 41, 1215-7(1915).—Mucoid purulent sputum contained 105.2 and 109.5 mg. Ca per 1000 parts, serous mucoid sputum 51.3 mg., while the mucus of this sputum contained 110.2 mg. Ca. It is seen therefore that the inflammatory secretion does not contain any more Ca than blood serum. The results of the exams. are summarized as follows: Normal (?) human bile of the gall bladder contains amts. of Ca varying between 85 and 352 mg. per 1000 g. bile. A definite increase of the Ca in the contents of an inflamed gall bladder cannot be shown. The Ca content of the liver bile obtained from a fresh fistula varies between 65.1 and 83.9 mg. per 1000 cc. bile. In a case of permanent bile fistula with repeated severe attacks of inflammatory bile occlusion the Ca content of the bile, which was very poor in solid residue, varied between 40 and 90.4 mg. per 1000 cc. In 3 days when attacks occurred the Ca content was slightly increased. Although the amt. of Ca of the bile excreted on these 3 days did not exceed that of bile excreted by a fresh fistula, the mucus secreted with the bile was considerably encrusted with "bilirubin-Ca," so that the concn. of the Ca in the mucus was 4-5 times as high as in the bile. S. AMBERG.

The significance of the dialysis method of Abderhalden in psychiatry. V. KAFKA. *Münch. med. Wochschr.* 62, 1316-20(1915).—K. describes an app. to facilitate the washing out of organs for the Abderhalden test. The paper gives a review of the subject based on the data contained in the literature and utilizing the author's own results. S. A.

Examination of tuberculous meningitis puncture fluids with the ninhydrin test. V. KAFKA. *Münch. med. Wochschr.* 62, 1355(1915).—The lumbar puncture fluid from

various diseases was examd. with the ninhydrin reaction according to Nobel. A positive reaction was obtained when the protein content of the fluid was distinctly increased. This means that the direct test cannot serve for the differential diagnosis of tuberculous meningitis. After dialyzing the spinal fluid and testing the dialysate it was found that the reaction was positive in cases of acute forms of meningitis. S. AMBERG.

The cholesterol content of cerebrospinal fluid. P. G. WYSON. State Hosp., Pa. *J. Med. Res.* 33, 119-26(1915).—Cerebrospinal fluids from the cadavers of 85 individuals who had suffered from various types of mental diseases all contained some cholesterol. The fluids were removed from the bodies as soon as possible after death, the time varying from 15 min. to 3 hrs. Neither the quantity of the fluid obtained nor the quantity of the cholesterol was found to bear any relation to the psychosis. The av. amt. of fluid found in cases of paresis and in arteriosclerotic dementia was greater than in the other cases. The av. amt. of cholesterol for cases of epileptic psychoses, dementia precox and organic dementia was greater than for cases of paresis, senile dementia and manic depressive psychoses. GEO. T. CALDWELL.

Relation of certain urinary findings to prognosis of pulmonary tuberculosis. J. C. CUMMINGS. Sacramento. *Calif. State J. Med.* 13, No. 10(1915); *J. Am. Med. Assoc.* 65, 1584.—In 100 cases, of which only 14 were considered clinically "favorable," C. applied the urochromogen and diazo tests. None of the 14 gave a positive urochromogen reaction, while in 39 of the remaining 86 the test was positive. Seven of the 14 and 51 of the 86 gave a positive diazo reaction. L. W. RIGGS.

Critical considerations of the histochemical foundations of cholesterol-steatosis. TH. E. H. THAYSEN. *Centr. Path.* 26, 433-51(1915).—Results by any of the microchem. methods do not correspond to the results of direct analysis, and therefore the latter is the only reliable method for demonstrating the existence of cholesterol-steatosis.

ALFRED N. RICHARDS.

Use of selenium compounds in the therapy of malignant tumors of animals and man. H. COENEN AND W. SCHULEMANN. *Deut. med. Wochschr.* 41, 1213-5(1915).—"Eosin-Se," prepared according to Wassermann, was dissolved in water and acidified with mineral

acid. A ppt. is formed. On extrn. with Et_2O , eosin free from Se is obtained, while the Se remains in the water. On treating the "eosin-Se" with abs. alc. the Se is removed. In a control expt. it was shown that Se cannot be removed by these methods from a truly substituted "eosin-Se." The prep. of Wassermann is regarded as a Na salt of eosin on which there is some dried KCNSe. Various fluorescein derivs. were injected in tumor mice and it was found that the living tumor cells have no special affinity for these dyes. Injections of KCNSe in normal mice produced hemorrhages in various organs, occasionally necroses in the liver. Injection in tumor mice produces hyperemia and hemorrhage in the tumor. It is to be noted that KCNSe produces hemorrhages much more readily in mice than in rats or rabbits. It is shown in mice with tumor transplants that the life, particularly of the cells of the mouse carcinoma, is dependent upon the vessels. The possibility is pointed out that the action of "eosin-Se" of Wassermann is nothing but a KCNSe action on the walls of the newly formed vessels of the mouse tumor affecting the tumor cells but indirectly. S. AMBERG.

The so-called vaccine- or bacterio-therapy: "Ergotrope" therapy of typhoid fever. F. v. GROER. *Münch. med. Wochschr.* 62, 1312-3, 1344(1915).—"Typhin A. No. 2" is a protein-like substance derived from typhoid bacillus by chem. means. Its solns. are water-clear, and can be sterilized. It is antigenic in character, and is hardly less active than the "living sensitized" Bearedka vaccine. Its dosage is detd. gravimetrically, and not by number of bacilli per cc. Simultaneously 1.5 mg. is given intramuscularly and 1.5 mg. intravenously. In this way the danger of collapse possible on intravenous injection of 2 mg. is obviated, while the effect appears a few hours later. In lighter cases of typhoid fever 8-10 mg. are given intramuscularly. The effects of the intravenous injection are about those that follow the injection of Bearedka vaccine. The curative effect must be due to a change of the reactivity of the organism toward the infecting agent. In contrast to the parasitotrope therapy which is directed against the parasites or their products as in chemo- and serotherapy, it is proposed to designate this new kind of therapy as "ergotrope" therapy. S. AMBERG.

The behavior of urinary nitrogen in acute nephritis from corrosive sublimate and the prognostic value of the curve of urea elimination. PIETRO MONTUSCHI. Florence. *Arch. farm. sper.* 20, 194-210(1915).—After a very brief period of scanty elimination of urea coincident with a diminution of diuresis, a high and prolonged excretion of urea may be regarded as an indication of probable recovery from HgCl_2 poisoning. On the contrary, where a continued decrease in urea is noted, the cases generally result fatally. A. W. DOX.

The possibility of producing nephritis by introducing into the circulation substances capable of exerting only a mechanical action. PIETRO MONTUSCHI. Florence. *Arch. farm. sper.* 20, 269-75(1915).—Serious lesions of the kidney are caused by the injection of lampblack, Chinese ink, BiONO_3 , ibit, ivory black and colloidal carbon. A. W. D.

α -Copper gynocardate and its value in tuberculosis and leprosy. I. I. OSTROMUSLENSKII. *J. Russ. Phys. Chem. Soc.* 47, 335-63(1915).—Numerous pharmacological expts. with α -Cu gynocardate (*a*) (*C. A.* 10, 44) gave the following results: The life of guinea pigs infected with tuberculosis is considerably prolonged by subcutaneous injections of *a*, though no complete cure has so far been effected. Healthy animals seem to be protected by it against infection. Theoretically *a* ought to be effective against leprosy, particularly when the latter is accompanied by papules. *a* may be used in 1% soln. in olive oil or in 1-4% soln. in Me gynocardate, but not in free oleic acid, the latter being liable to produce local reactions. The soln. of *a* should be fresh, made transparent by filtration if necessary, sterilized at 130-50°, and should not be supersatd. Successive injections of small amts. are to be preferred to single injections of larger amts. The injection should not be intravenous. H. M. GORDIN.

The action of benzene. I. The significance of myeloid metaplasia of the spleen. H. G. WEISKOTTEN, S. C. SCHWARTZ AND H. S. STRENSLAND. Syracuse Univ. *J. Med. Res.* 33, 127-40(1915).—Following the subcutaneous administration of equal parts of olive oil and benzene, there occurs in rabbits a rapid decrease in the number of leucocytes in the peripheral circulation. Following this primary fall in the leucocyte curve, there occurs a primary rise, which is followed by a secondary fall before a permanent rise to a normal level. The polynuclear leucocytes are especially affected. In rabbits in which the injections are begun 2 days and 6 months, resp., after splenectomy, the leucocyte and erythrocyte curves are essentially the same as in the non-splenectomized rabbits which receive like injections and the duration of the periods of regeneration is essentially the same. The differential counts on the non-splenectomized animals and on those splenectomized 2 days and 6 months previously show no essential differences and the blood pictures are otherwise the same. In the rabbit, the spleen seems to serve no essential function in the destruction of leucocytes and erythrocytes, following subcutaneous injection of the olive oil-benzene mixt. (or in their subsequent regeneration). Any destructive or regenerative function that it has is quickly assumed by some other part of the body when the spleen is removed. GEO. T. CALDWELL.

I. ZOÖLOGY.

R. A. GORTNER.

Amino acids and the production of silk in the larvae of Bombyx mori. Experiments with aminoacetic acid. LUCIANO PIGORINI. Univ. Padua. *Arch. farm. sper.* 20, 225-57(1915).—Since the fibroin of silk is characterized by its high glycine content, the author attempted to increase the yield of silk by feeding glycine to the silkworms. Four lots of 50 worms were fed (a) natural leaves, (b) leaves dipped in water, (c) leaves sprayed with a 2.5% soln. of glycine, and (d) leaves with a 11.4% soln. of sucrose (equimolecular to the glycine). The results are tabulated as follows: Wt. of cocoon $b > c > a > d$; dry wt. of cocoon $d > a > b > c$; N in cocoon $c > a > b > d$; silk in cocoon $b > a = c > d$; N in chrysalis $a > c > b > d$; N in silk $c > d > b > a$; fibroin in silk $c > d > b > a$. A. W. DOX.

Light production by luminous bacteria. E. N. HARVEY. *Am. J. Physiol.* 37, 230-9(1915).—Dried luminous bacteria, even though dead, phosphoresce when moistened with O-containing H_2O but not with O-free H_2O . When finely ground with sand the luminous property is lost; hence it depends on the integrity of some cellular structure. Luminous substances could not be extd. by Et_2O , toluene, or cold absolute EtOH, the bacteria retaining the property of phosphorescence. When cytolyzed by Et_2O or toluene either in the absence or presence of O the luminous substance is rapidly destroyed. Moist bacteria extd. with EtOH lose their luminous power. H. believes that in photogenesis there is involved a substance which in the moist state is irreversibly pptd. (or changed) by EtOH and that it is probably protein in nature. J. F. LYMAN.

12. FOODS.

W. D. BIGELOW, F. F. FITZGERALD.

Food chemistry in 1914. J. RÜHLE. *Z. angew. Chem.* 28, I, 397-401, 405-8, 416-9, 431-2(1915).—A review with numerous references to the literature. E. J. C.

Contributions of the chemist to the packing house products industry. ARTHUR LOWENSTEIN. *J. Ind. Eng. Chem.* 7, 942-4(1915).—A part of the symposium at the Seattle meeting of the Am. Chem. Soc. E. H.

Sugar in fruit sirup of the German Pharmacopeia. ROBERT COHN. *Pharm. Ztg.* 60, 416-7(1915). W. O. E.

Table sirups other than maple. ALP. LÉMOINE. Inland Revenue Dept., Ottawa, Canada, *Bull.* 320, 23 pp.(1915).—Analyses are given of 200 samples collected in Canada. They are classified as follows: Cane sugar sirups 49, essentially glucose sirups 109, mixtures containing a considerable % of cane sugar sirup 27, molasses 15.
E. H.

Lime juice. A. MCGILL. Inland Revenue Dept., Ottawa, Canada, *Bull.* 321, 13 pp.(1915); cf. C. A. 9, 940.—Analyses are given of 83 samples, of which 27 were found to be adulterated.
E. H.

Contribution to the investigation of sugar for feeding. v. WISZELL. Danzig. *Chem. Ztg.* 39, 769-70(1915).—Crude sugar denatured with chopped straw, chaff, bran, sun-flower and hemp-seed meal gave too low results by the polariscope compared with gravimetric results by the inversion method, and investigations showed that the discrepancy was due to inversion in the presence of moisture. The polariscope tests should be checked gravimetrically.
J. H. MOORE.

Chop feed. A. MCGILL. Inland Revenue Dept., Ottawa, Canada, *Bull.* 319, 21 pp.(1915).—Analyses are given of 149 samples collected in Canada. Of these 24 were found to be adulterated.
E. H.

Effect of storage on the moisture content of cloves (OGDEN) 17. **Separation and determination of peptones** (VLÁHUTÁ) 7. **Starch in industry** (MATTHIAS) 28.

Sterilizing foods. F. GARPHEIDE. Brit., 1,018, Jan. 14, 1914. The app. comprises a cylinder in which a piston is advanced by means of a screw cap, and which is filled with a compressing fluid or pickle.

Drying and preserving food products. W. D. EDWARDS and T. E. KOEHLER. Brit., 15,662, June 30, 1914. Food products, such as fruit and vegetables, are cooked, or cut and treated with cold H_2O , or subjected to both these treatments, and then subjected to the drying action of air having a determinate degree of humidity short of satn.; afterwards they may be steamed or stood in heaps and "sweated" by the heat spontaneously generated. The app. is specified in detail.

Food from wood. J. KÖNIG. Brit., 8,006, Mar. 30, 1914. Wood is treated under pressure in a digester with dil. mineral acids or with dil. alkalis. The liquid which is sepd. is rich in sugar and may be evapd. to dryness, used as subsequently described, or treated to recover alc., adhesives, resin, tannic acid, etc. The wood residue is digested to remove sugar and acid, and the resulting liquid may be used for treating a fresh charge of wood. $Ca(HSO_3)_2$ is added to the wood residue in the digester and heated. The sulfite liquor contains substantially only lignine and is heated to expel free SO_2 , aerated by falling down a tower containing limestone, etc., and passed into a pit where the gypsum is allowed to settle. The clear liquid, alone or mixed with the liquid rich in sugar previously obtained, or with liquors remaining after alc. fermentation of this liquor, is evapd. to dryness and employed alone or mixed with spent malt, etc., as fodder. Resin can be recovered, in treating coniferous wood, from the sugar liquid by neutralizing with NH_4OH , etc., or by neutralizing the ext. obtained when dil. H_2SO_4 is used, with $CaCO_3$, and allowing the resin to sep. The remaining liquid is an almost pure sugar soln., which can be fermented or worked into sirup. To recover tannic acid, the sugar liquid, after removal of the resin, is concd. By eliminating the lignine contained in the residue left after the preliminary treatment by treatment with bleaching powder, etc., a purer cellulose is obtained than by the well-known sulfite process. The cellulose so obtained is suitable for the prepn. of artificial silk and nitro-cellulose.

Kola preparations. G. C. ZIMMERMANN. Brit., 15,725, July 1, 1914. Kola nuts are disintegrated, allowed to ferment, and roasted. An ext. obtained by boiling the product with H_2O may be used directly as a beverage or concd. with sugar.

Fodder and cellulose. J. KÖNIG. Ger., 284,715, Feb. 3, 1914. Materials containing cellulose, especially wood of all kinds, are subjected first to a pretreatment with dil. mineral acids (H_2SO_4 or HCl) and dil. alkalies (preferably NH_4OH), or with one of these solns. alone, with heating under varying pressure. The materials are then treated further according to the usual sulfite process, and the resulting sulfite liquors, after complete neutralization and sufficient aeration, are evapd., alone or preferably together with the first disintegrating liquid rich in sugar or gum, and worked up further, in the usual manner (cf. 265,483, C. A. 8, 386), to a fodder. In case the first disintegrating liquid, rich in sugar or gum, has served for the manuf. of alc. or for the production of any by-products, the residual liquid from such treatment is evapd. with the sulfite liquor, and worked up further into fodder. In experience, an average of 4.0-5.5 kg. alc. can be obtained from 100 kg. wood, and the fermentation residues can be worked up into a fodder. The subsequent evapn. with $CaSO_4$ yields, according to the kind of wood, 8-15% of organic substances. In spite of the low sugar content the mass, mixed with dry brewer's husks, is taken by animals with relish.

Caffeine-free coffee beans. L. KLEIN. Ger., 284,374, Feb. 19, 1910. Addition to 276,014 (C. A. 9, 493). In the parent process the extn. of the caffeine may be effected, generally, with mixts. of alk. caffeine solns. As a rule the mixts. appear to exert a better action than the alkalies or alkali solvent employed heretofore. Further advantage is secured in that, according to the nature of the mixt. employed, the extn. of the caffeine can be carried to any desired extent. E. g., by the employment of a mixt. of lime-water and any one or several alkalies, 100 kg. of beans are treated, according to the parent process, with 400-500 kg. of a liquid containing $Ca(OH)_2$ to which 2-2.5 kg. of the other alk. agent is added (K_2CO_3 , KOH , $NaOH$, and the like) for a period of 3-5 hrs., whereby the caffeine content of the beans is reduced from about 1.2% to 0.17-0.15%.

Coffee, tea, and like effusion beverages. A. KLIMA. Ger., 284,266, Sept. 24, 1913. The coffee powder or the like is softened first by steam, then extd. by a mixt. of hot H_2C and steam, and the residual extractive matter removed by steam.

14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW.

Misbranding of "White Stone Lithia Water." U. S. Dept. of Agr., *Service and Regulatory Announcements*, 10, 569.—Condemned because it was not a lithia water and did not contain ingredients capable of producing the therapeutic effects claimed
E. BARTOW.

Pressure scraping fifteen miles of water mains. JAMES MACFADZEAN. *Surveyor* 47, 772-4 (1915).—Scraping a main of 8 miles 16-inch and 6.5 miles 14-inch pipe increased the delivering capacity 618,000 gals. per day, 36.5% of the capacity before cleaning. Nodules up to $\frac{1}{8}$ inch thickness and $2\frac{1}{2}$ inch diam. made up the greater part of the material removed. Analysis showed Fe_2O_3 7, FeO 2.57, Al_2O_3 0.49, CO 1.12, P_2O_5 0.43, SO_3 0.56, SiO_2 0.36, H_2O and org. matter 24.42%. In 2 years after cleaning the carrying capacity had decreased 276,000 gals. per day. "Before deciding to scrape a main the engineer should seriously consider whether the advantages to be gained will balance the deterioration due to more rapid corrosion, in addition to the cost of periodic scraping."
W. D. COLLINS.

The water supply of Bamberg (Germany). HOCHBERG. *J. Gasbel.* 58, 532-6 (1915).—The city is supplied with ground water. The av. Fe content is 0.02 g. per 100 l.

ARTHUR LEDERER.

The water works of Senftenberg (Germany). K. WAGENFÜHRER. *J. Gasbel.* 58, 376-82, 405-7 (1915).—Three districts are provided with water. District 1 is supplied by ground water. The water is collected in a reservoir and then freed from the Fe, Mn, CO₂, and H₂S which it contains. The water is first aerated to remove as much as possible of the Fe and then passed through a layer of broken marble to take care of the CO₂. Permanganate is added to destroy as much of the org. matter as possible. This water passes a layer of sand and permutite to eliminate the Mn. A vacuum plant removes the excess air and the H₂S in the water. The final effluent is clear, odorless, and free from colon bacilli. District 2 is likewise supplied by ground water. The Fe is removed in an open plant and the aerated water is filtered. Purple windows are installed at the Fe removal plant to prevent the growth of detrimental algae. District 3 is supplied by a small ground water plant.

ARTHUR LEDERER.

Influence of potash waste liquors upon crops. E. HASLHOFF. *Gesundh. Ing.* 38, 429-32 (1915).—H. discusses the work done on this question, particularly that of Stutzer and Haupt. He states that Stutzer and Haupt do not answer the question whether potash liquors influence crops adversely. Their expts. should have covered a longer period. The question is still an open one.

ARTHUR LEDERER.

The clarification plant of the slaughtering house at Lille (France). P. KEM. *Gesundh. Ing.* 38, 349-50 (1915).—The plant consists of a Kremer tank, septic tank, and intermittent sprinkling filters. The sludge is removed 4 to 5 times daily in small quantities and mixed with other fertilizer material. The period of flow in the septic tank varies greatly. The filter effluent is clear and contains but little suspended matter; it has a slight humus odor.

ARTHUR LEDERER.

The disposal of liquid wastes from manufacturing processes. H. MACLEAN WILSON AND H. T. CALVERT. West Riding of Yorkshire Rivers Board. *Surveyor* 48, 228-31 (1915).—Report to Rivers Board commenting on the recommendations in the 9th report of the Royal Commission on Sewage Disposal. The opinion that trade refuse should generally be treated by sanitary authorities along with domestic sewage is sound. Advances in methods of treatment are most likely to come from the work of manufacturers or chemists and engineers employed by them, as nearly all the processes now in use have been so developed. It is claimed that the classification of certain wastes and the proposed standards for some effluents are not in accordance with the latest practice, nor wholly justified by evidence given in the report. In regard to suggested changes in the laws, "it is difficult to see that this (the proposed) mode of legal action is any better than that under the existing law."

W. D. C.

Milwaukee's activated sludge plant, the pioneer large-scale installation. T. C. HATTON. *Eng. Record* 72, 481-4 (1915); *Eng. News* 74, 667-8 (1915); *Surveyor* 48, 258-61 (1915); cf. *C. A.* 9, 2412.—The plant consists of 11 circular reinforced-concrete tanks 30 ft. inside diam. by 13 ft. max. depth. Tanks 1 to 6, inclusive, are the aerating tanks in which the sewage mixed with activated sludge is aerated. Tank 9 is used as the sedimentation tank and tanks 10 and 11 are the activated sludge tanks. Drawings are given showing the curved baffles and the manner of sloping the bottom of the running-through channels of the aerating tanks. The sewage enters tank 1 and is aerated with the sludge, then passes to tank 2 and is again aerated and so passes through the other tanks to tank 9 where it is settled. The sludge from this tank is discharged by gravity into tanks 10 and 11 where it is aerated to maintain the N cycle. From these tanks the sludge is pumped to the inlet chamber of tank 1. Activated sludge which is

in excess of that needed is dried and used for fertilizer. The plant is designed to treat 1.6 million gals. sewage per day with a 4-hr. period of aeration and with 25% activated sludge. It is estimated that the cost will be \$5.30 per million gals. exclusive of engine room and plant labor and the disposal of sludge. Cf. following abstract.

FRANK BACHMANN.

The world's first full scale plant for the treatment of sewage by the activated sludge process. T. C. HATTON. *Am. Soc. Municipal Improvements* 1915; *Eng. Contr.* 44, 322-7(1915); *Can. Engr.* 29, 517-9, 549-50(1915); cf. preceding abstr.—This describes tests on the activated sludge plant at Milwaukee showing bacterial removal of 99% and cost data indicating a partial cost of \$4.43 per mil. gal. of sewage when 1.7 cu. ft. of air are used per gal. of sewage. A stable effluent is produced with city sewage containing 250 p. p. m. of suspended matter. The sludge contains 5.45% NH_3 .

LANGDON PEARSE.

Test plant operated to deodorize oil refinery wastes. F. R. HESSER. *Eng. Record* 72, 541-2(1915).—The methods tried in an experimental plant to deodorize the wastes from the Standard Oil Co. refinery at Neodesha, Kan., were aeration, coagulation, sedimentation and storage. It is believed the odors from the waste are due to naphthalenic and sulfonic acids, partially in soln., and partially suspended as an emulsion. Results were recorded by the diln. giving the equivalent odor. Raw waste was usually detected in 1 to 1000 or 1 to 4000 dilns. Aeration at rate of 28 million gals. per acre per day or less on a coke filter gave an effluent equiv. to a 1 to 256 diln. Coagulation with lime and iron and subsequent aeration gave better results and plain storage for periods of 24 hrs. or more effected a reduction of 25% in some cases. Diln. of 1 to 256 represented a reduction of odor of 75% or more.

FRANK BACHMANN.

Method and cost of refuse collection and disposal in Los Angeles, Calif. A. C. HANSEN. *League Calif. Municipalities* 1915; *Eng. Contr.* 44, 255-6(1915).—In Los Angeles, garbage, non-combustible and combustible rubbish and market refuse are separated. The regulations, details and costs are given. A reduction plant is now operating.

LANGDON PEARSE.

Incineration of Atlanta garbage. E. R. CONANT. *Eng. Record* 72, 532(1915).—About 27,000 tons were incinerated at a cost of 91 cents per ton. The refuse consists of 40-45% of garbage, 50% rubbish and 5-10% of ashes. The clinker from the plant varied from 20 to 30% and was sold for use in hardening streets.

F. BACHMANN.

Detection and estimation of traces of phosphoric acid (MEDINGER) 7. The alkalies of Montreal (CUMMING) 8. Mineral springs of southeast Mährens (SCHUBERT) 8.

Removing temporary hardness from water. K. SCHREMPF. *Brit.*, 2,971, Feb. 5, 1914. The water is heated and then the pressure is suddenly reduced. H_2O heated below the b. p. may be passed into a vessel in which there is a partial vacuum. If heated above the b. p. under pressure may be passed into an open vessel. Pressure may be exerted on the H_2O by a pump, steam injector, or other mechanical means before, during, or after the heating.

Sterile drinking water. J. W. MACKENZIE. *Brit.*, 15,366, June 26, 1914. Equal amounts of $\text{K}_2\text{Mn}_2\text{O}_8$ and $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$, which are subsequently pptd. by H_2O_2 , are added to the H_2O . The reagents may be added in the form of tablets.

Sterilizing and removing iron from water. B. KOHNSTEIN and J. M. MUCHA. *Brit.*, 2,020, Jan. 26, 1914. The H_2O is filtered through or otherwise treated with absorbent such as charcoal or kaolin which has been satd. with tannin, gallic acid

phenols, and their derivs., phenolsulfonic acids, alone or in admixt., or their condensation products with HCHO .

Sulfur furnaces for fumigating. C. D'OGNY. Brit., 16,523, July 10, 1914. App. for producing a mixt. of SO_2 and air for fumigating, disinfecting, extinguishing fires, destroying rats, etc., comprizes a S furnace, a filter, 1 or more suction devices for admitting an adjustable amt. of air, which may be drawn from the room, etc., to be fumigated, 1 or more pulsating gas propellers, which act also as coolers, a d. gage for indicating the proportion of SO_2 , and a distributing box. In the furnace the S, pyrites, or S and coal, is burnt in troughs, and air entering through an aperture is directed on to the S, etc., by inverted troughs.

15. SOILS AND FERTILIZERS.

R. O. E. DAVIS.

The properties of soil particles and the plasticity of soils. A. ATTERBERG. *Koll. Clem. Beihefte* 6, 55-89 (1914); cf. C. A. 6, 1060, 1331; 8, 221, 2020, 2588.—To obtain particles of different sizes (from 5 mm. to 0.001 mm.) gravel, coarse, medium and clay sand of glacial origin from the Kalmar region, and silt from north Sweden were used. The raw material was freed from Al_2O_3 and humus substances by treatment with acid and alkali. The coarser particles were sepd. by means of sieves. The finer sands were sepd. into the desired sizes by means of the sedimentation app. of Kopecky (*Die Bodenuntersuchung*, Prag, 1901). The finest particles were obtained by sedimentation in wide low glass cylinders by controlling time of this process. By these means the soil was sepd. into particles of sizes: 5-2 mm., 2-1 mm., 1-0.5 mm., 0.5-0.2 mm., 0.2-0.09 mm., 0.09-0.04 mm., 0.04-0.02 mm., 0.02-0.009 mm., 0.009-0.004 mm., 0.004-0.002 mm., and 0.002-0.001 mm. The particles larger than 0.02 mm. were true sands; the smaller particles were silt. Analysis showed the soils to consist mainly of K feldspar, Na feldspar and quartz and only in the very finest particles could mica be detected with the microscope. On drying, the particles larger than 0.02 mm. were of a loose, sandy consistency, while those smaller than 0.02 mm. formed cakes, the cohesion of the particles being in proportion to their sizes. By allowing 10 g. of the soils to stand over H_2O for 2 days at 16° and weighing, it was found that particles larger than 0.02 mm. were not hygroscopic. The space vol. between the particles was detd. by weighing the amt. of H_2O the particles would take up; it was found to be between 40 and 42%. The capillarity detns. showed that most of the water rose in the tubes of the sands the first 24 hrs. and that the rise during the next 24 hrs. was small. The capillarity increased from the larger particles to those of size 0.04-0.02 mm., where the max. was reached. In the smaller particles the capillarity decreased greatly. In detg. the amt. of H_2O the soils would hold upon pouring the H_2O on them it was found that particles from 5 to 0.2 mm. held from 4 to 8 vol. % H_2O according to size, and the particles from 0.2 to 0.009 mm. held 25 vol. % H_2O . The point of sepn. of soils which hold H_2O and which do not hold H_2O is therefore 0.2 mm. The size of soil particles has a great influence on vegetation as is shown by the fact that root hairs of papilionaceous plants could not penetrate soils with particles smaller than 0.03 mm. and the hairs of the roots of gramineous plants could not penetrate soils with particles smaller than 0.02 mm. In expts. to det. the coagulation of soil suspensions by means of acids, alkalies and salts it was found that particles of 0.04-0.02 mm. size show evidence of coagulation but the decided coagulation is only evident in particles smaller than 0.02 mm. Except in the case where lime water was used as a coagulant the sediments were fluid in properties and would not become hard. This explains the property of microscopic sands to remain fluid. Brownian movement was found in soil particles smaller than 0.002-0.001

mm. The committee of agrogeologists which was appointed at Stockholm in 1910 to standardize methods of mechanical soil analysis later adopted the division of soil particles as suggested by A. into the following sizes: larger than 20 mm. as stones, from 20 to 2 mm. as gravel, from 2 to 0.2 mm. as coarse sand, from 0.2 to 0.02 mm. as fine sand, from 0.02 to 0.002 mm. as silt and smaller than 0.002 mm. as colloidal particles. The sedimentation app. as described by A. was also adopted by this committee as a standard. The different methods for detg. the plasticity of clays are discussed, and former work reviewed (cf. C. A. 6, 1060). In the division of clays into 2 classes, sticky and non-sticky, it was found that in the mechanical analysis of the 1st class the proportion of colloidal particles lies above 50% and of the 2nd class the proportion of fine sand or silt lies above 50%. It is easier and quicker to det. the plasticity and the limits of stickiness of clays than to carry out a mechanical analysis of the soils. W. F. Z.

The application of potassium permanganate for the determination of humus of soils. N. P. GRIGORIEV. *Russ. J. Exp. Landw.* 16, 217-22(1915).—The nature of the oxidation of humus by KMnO_4 is considered. It is shown that the figures obtained are not in concordance when the oxidation method and the method of Goustavsohn are compared, the results in the former case being too high. From this it is concluded that the oxidation method cannot have preference over the combustion method.

W. H. FRY.

Soil acidity and methods for its detection. E. TRUOG. *Science* 42, 505-7(1915).—T. holds that soil acidity is due to true acids and not to colloids. Small amts. of very finely powdered soil were thoroughly shaken with comparatively large amts. of the respective salt solns. for a short period and then quickly filtered and the acidity of the filtrate detd. When this was done the soil took up very nearly equiv. amts. of different bases from salts having a common acid ion. To quantitatively det. soil acidity T. treats 25 g. of soil in a casserole with 35 cc. of water, and then adds an excess of $\text{Ba}(\text{OH})_2$ soln. This is allowed to act for 1 min. with const. stirring and then CO_2 is immediately passed in, changing the excess of hydroxide to the carbonate. The material is evapd. to complete dryness on a steam bath, and then the excess of hydroxide is measured by detg. the carbonate present. A special form of app. has been devised for this detn. When the detn. is made by this method it makes little difference whether Ca, Ba or Na hydroxide is used to neutralize the acidity. If soil acidity is due to colloids, then according to the properties of colloids it should take different chem. equivalent amts. of Na, Ba and Ca hydroxides. This again indicates very strongly that soil acidity is due to true acids and not to colloids.

R. C. ROARK.

A new test for soil acidity. E. TRUOG. Wisconsin Agr. Expt. Sta., *Bull.* 249, 3-16(1915).—In a small Erlenmeyer flask place 9 cc. of the soil to be tested, 95 cc. of water and 5 cc. of a soln. containing CaCl_2 and ZnS (5 g. ZnS and 50 g. $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ added to 250 cc. water), and boil for 1 min. Then place a moistened piece of lead acetate paper over the mouth of the flask and boil the mixt. just 2 min. more. Dry the test paper and compare with a standard color chart (given in this bull.). A portable app. with an alc. lamp for use in the field is pictured and described. According to T. this test is better than others in that it is more positive, it indicates the degree of acidity, is not affected by CO_2 , and can be quickly made by anyone capable of following simple directions.

R. C. ROARK.

A new method for mechanical soil analysis. SVEN ODÉN. Uppsala. *Internat. Mitt. Bodenkunde* 5, 257-311(1915).—A method founded upon rate of sedimentation is discussed mathematically. The app. to be used is described.

W. H. FRY.

The characterization of soils on the basis of hydrochloric acid soil extracts and the power of exchanging bases. A. J. VON SIGMOND. Budapest. *Internat. Mitt. Bodenkunde* 5, 165-224(1915).—Detailed chem. analyses of HCl exts. gave characteristic

comparative values as to the soil-forming factors which could not be obtained by lump analyses.

W. H. FRY.

Losses of moisture and plant food by percolation. G. S. FRAPS. Texas Agr. Expt. Sta., *Bull.* 171, 5-51(1914).—As a result of 3 years' expts. with Texas soils in 12-inch pots it is concluded that uncultivated clays and loams allowed more water to percolate than uncultivated sands and sandy loams. Cultivation increased percolation through the sands and sandy loams, but had but little effect upon the percolation through the loams and clays. K_2SO_4 increased percolation through the sandy soils but decreased it through clay soils. Application of manure increased percolation from the sandy soils especially, application in the fall being more effective than in the spring. The nitrates in the water percolating from the uncultivated soils is related to a certain extent to the total N of soil and subsoil. Only small quantities of K appeared in the percolates from most of the soils even after heavy applications. In 3 years the max. loss was 12% with the Norfolk sand and from 0 to 4.5% with the other soils. Losses of P in the percolate were very small. Losses of CaO from the uncropped uncultivated soils vary from 70 to 582 lbs. per acre and are in a general way related to the amt. of CaO sol. in strong HCl.

R. C. ROARK.

The movement of soluble salts with the soil moisture. F. S. HARRIS. Utah Agr. Expt. Sta., *Bull.* 139, 119-24(1915).—The results of expts. on the horizontal and vertical movement of salts in soils are recorded. They show that salts are transferred through the soil very readily by moving water. H. concludes that it is probable that low lands will continue to be ruined by the accumulation of alkali salts as long as the uplands are over-irrigated.

R. C. ROARK.

Nitrification. I. Preliminary observations. E. R. ALLEN AND A. BONAZZI. Ohio Agr. Expt. Sta., *Tech. Bull.* 7, 5-42(1915).—A critical review of present methods of studying nitrification with suggested means of improvement. A bibliography of 42 titles is given.

R. C. ROARK.

A new nitrite-forming organism. N. V. JOSHI. *Mem. Dept. Agr. India (Bact. Ser.)* 1, 85-96(1915).—By inoculating a soln. of $(NH_4)_2SO_4$, K_2HPO_4 , $MgSO_4$, NaCl, $FeSO_4$, and $CaCO_3$ with a Pusa soil a new NO_2 -forming organism corresponding to the description of *B. oligo-carbophilous*, but having distinctly different morphological characters, was detected. In the culture media it had the appearance of a mass of ramifying threads which occurred in thin pellicles dotted with white, chalky prominences. The optimum temp. for its activity is between 25° and 35° and its thermal death point is between 70° and 80° . $MgCO_3$ is much less effective than $CaCO_3$ as a base for NO_2 -formation by this organism. An addition of glucose to the culture soln. retards NO_2 -formation, while 50 to 100 p. p. m. of CO_2 stimulate and larger amts. retard its activity. 0.1 g. asparagine and 0.2 g. urea in 50 cc. of soln. increase NO_2 formation. In P-containing solns. NH_4Cl , $(NH_4)_2SO_4$, $(NH_4)_2CO_3$, asparagine and urea serve as sources of N for NO_2 formation. In solns. containing no P, $(NH_4)_2CO_3$ is the only substance which is easily changed into NO_2 by the organism. In solns. of $(NH_4)_2CO_3$ and urea, $CaCO_3$ exerts an inhibitory influence on the activity of the new organism.

J. J. S.

Soil protozoa. GEO. P. KOCH. N. Jersey Expt. Sta. *J. Agr. Research* 4, 511-59 (1915).—The loop method for counting bacteria was improved by using a wire bent into a permanent loop with an angle of $30-35^\circ$ and the quantity of soln. that could be transferred to a ruled slide carefully detd. The av. error is about 7%. Numerous expts. under different soil conditions showed that the max. development of ciliates and flagellates varies with the culture soln. and the condition and amts. of soil used in the expts. For the development of all forms soil ext. seemed a little more favorable than dried-blood ext. The development of protozoa was studied in different culture solns. with varying amts. of soil inoculations, and a comparison made of the numbers and types

Chemical Abstracts.

ed from compost and field soils. Every variation in the amts. of culture soln. used caused the development of different numbers and A temp. of 15-16° is most favorable for small ciliates and at this is most favorable. Large ciliates will develop at all temps. noted, favorable otherwise. Many flagellates developed at all temps. but it was at 6-7° in dried blood and at 15-16° in hay infusion.

R. O. E. DAVIS.

and nitrogen fixation in Indian soils. J. H. WALTON. *Mem. Dept. Agr. Ser.* 1, 97-112 (1915).—Working with soil from 6 provinces of India at this organism is more active in the Pusa soils than in other sections. *Azotobacter* isolated from the different soils vary in N-fixing power, morphological and cultural characters. These morphological and cultural characters are different in any particular variety. There is a well-marked, seasonal variation in cultures inoculated with soil. The addition of urea, $(\text{NH}_4)_2\text{SO}_4$, asparagine and casein to the culture media had only a small influence on the fixation of N by *Azotobacter*. Basic slag considerably affected N-fixation. The physiological activities of this organism are increased in the soil by presence of Ca and of available carbohydrate food. J. J. S.

of temperature on movement of water vapor and capillary moisture in soils. Mich. Agr. Expt. Sta. *J. Agr. Research* 5, 141-72 (1915).—When a column of soil of uniform moisture content is maintained at 20° and 40° for 8 hrs. the % water moved from the warm to the cold soil is half at 0° for 8 hrs. the % water moved from the warm to the cold soil in all the different types of soil with a rise in moisture content until a certain content was reached, and then it began to decrease again with further increase in moisture content. The results plot into a parabola. Moisture % at which maximum translocation occurred is designated as the "thermal critical moisture content." Results lead to the conclusion that the capillary movement of water in moist soil is not controlled entirely by the curvature of the capillary films, but also by the attractive forces of the soil for water. When a moist column of soil was placed between a dry column of soil at 20° and 40° and a dry column of soil at 0° for 8 hrs., the 2 columns being separated by a thin space, the % moisture distd. over from the moist and warm column to the dry column was very insignificant for both amplitudes of temp. and was the same for all moisture contents. This leads to the conclusions that the amt. of water lost from the soil by water vapor is very small, that there is no rise of vapor from the soil at night from the warmer soil below to the cold soil above, and that the water loss is not derived from the soil vapor. When a moist column of soil was in contact with a dry column of soil and the former was kept at 20° and 40° and the latter at 0° for 8 hrs., the amt. of moisture moved from the moist and warm soil to the dry and cold soil was maintained with temp. and with moisture content. But when the moist column of soil was maintained at 0° and the dry column of soil at 20° and 40° for the same number of hrs. there was very little, if any, movement of water from the former to the latter. This has a very marked influence on the conservation of moisture by mulches.

W. H. FRY.

effect of heat upon soil fertility. Wm L. OWEN. *Sugar* 17, No. 10, 31-2 (1915).—The theory of Russell and Hutchinson (cf. C. A. 4, 290) is presented together with a description of the work of a number of investigators whose expts. indicate that the beneficial effect is due to conditions other than the destruction by heat of certain bacteria in the soil which are predacious toward the beneficial bacteria.

A. GROSS.

soil, and fertility studies with roses. MAURICE A. BLAKE. N. Jersey Agr. Sta. *Bull.* 277, 5-55 (1915).—The sources of N best suited to the needs of

the florist, and amts. to use per 100 sq. ft., are: dried blood, 5 to 8 lbs.; dried fish, 7.5 lbs.; cottonseed meal, 10 lbs.; and NaNO_3 , 4 to 5 lbs. As a source of P, the author prefers acid phosphate, to be applied at the rate of 4 lbs., and as a source of K, K_2SO_4 , to be applied at the rate of about 12 oz. per 100 sq. ft. of bench surface. Ground limestone is the best way in which to apply Ca, 15 to 25 lbs. per 100 sq. ft. being most desirable for New Jersey soils.

R. C. ROARK.

Ammonification studies with soil fungi. HARRY C. McLEAN AND GUY W. WILSON. N. Jersey Agr. Expt. Sta., *Bull.* 270, 3-39(1915).—Of the fungi studied, including members of the Aspergillaceae, Mucoraceae, Dematiaceae and Moniliaceae, all were found to have the power of ammonifying both cottonseed meal and dried blood. With but a single exception increased growth of mycelium in the soil is accompanied by increased NH_3 accumulation; all of the cultures were pure according to inoculation. Fungi belonging to the Moniliaceae were the most active ammonifiers. In the soils containing 155 mg. of N in dried blood and inoculated with *Trichoderma Koenigii* Strain v. 3, 49.29% of the organic N was accumulated as NH_3 in 7 days. With acid phosphate added, the accumulation was increased to 59.01%; with cottonseed meal as a source of organic N the ammonia N accumulation was 27.48% and the addition of acid phosphate depressed it. The Aspergillaceae showed the least ammonifying power. When dried blood was used as a source of N, acid phosphate increased NH_3 accumulation in the soils with 18 out of the 26 pure cultures of fungi studied. On the other hand, with cottonseed meal as a source of N, NH_3 accumulation was increased only in the case of 8 out of the 25 cultures studied. All of the fungi with the exception of four, viz.: *Zygorrhynchus ouilleminii*, *Rhizopus nigricans*, *Monilia silophila*, and *Mucor hiemalis* were able to ammonify dried blood more readily than cottonseed meal. The results of these expts. show that ammonification of the soil organic matter by fungi depends not only upon the chem. and physical compn. of the soil, but also upon the quality of the organic matter present as well as on the presence of sol. phosphates.

R. C. ROARK.

Relation of sulfur compounds to plant nutrition. E. B. HART AND W. E. TOTTINGHAM. Univ. Wisc. *J. Agr. Research* 5, 233-50(1915).—Greenhouse studies with one type of soil indicate that certain plants are measurably increased in their growth by the addition of sulfates, but sulfates have very little effect as compared with sol. phosphates. Plants most affected were Leguminosae and Cruciferae. There was noticeable stimulation to seed production in both barley and oats, although there was little or no effect on the development of the quantities of straw. With clover, the increase of air-dried matter due to CaSO_4 alone was about 23%. With rape, CaSO_4 superimposed upon a complete fertilizer gave an increase of 17% over the complete fertilizer. A similar order of increase was observed with radish, 9% above complete fertilizer. CaSO_4 was more effective than Na_2SO_4 . Sulfates were particularly effective on the root development of red clover and rape. Elemental S was generally harmful, even in the presence of a generous supply of CaCO_3 .

W. H. FRY.

Effect of alkali salts in soils on crops. FRANK S. HARRIS. *J. Agr. Research* 5, 1-53(1915).—Many expts. carried out to det. the effect of varying amts. of alkali on plant growth, and results of over 18,000 tests are given. Only about half as much alkali is required to prohibit the growth of plants in sand as in loam. In seedling stage, barley is most resistant, followed in order by oats, wheat, alfalfa, sugar beets, corn and ~~Cornfield~~ peas. Results on toxicity in soln. do not hold when the solns. are ~~soil~~ ^{soil}. The anion or acid radical detd. the toxicity of the alkali. Toxicity of salts is in the following order: NaCl , CaCl_2 , KCl , NaNO_3 , MgCl_2 , KNO_3 , $\text{Mg}(\text{NO}_3)_2$, Na_2SO_4 , K_2SO_4 , and MgSO_4 . Percentage of H_2O influences the toxicity. Without ~~re~~ ^{ammon} ~~ation~~, soils with more than the following amts. are not suited

to cultivation: in loam, chlorides 0.3%, nitrates 0.4%, carbonates 0.5%, sulfates above 1.0%; in coarse sand, chlorides 0.2%, nitrates 0.3%, carbonates 0.3%, and sulfates 0.6%.

R. O. E. DAVIS.

The influence of certain organic materials upon the transformation of soil nitrogen. R. C. WRIGHT. *J. Am. Soc. Agron.* 7, 193-208(1915).—With a sandy loam and a clay loam to which $(\text{NH}_4)_2\text{SO}_4$ was added rotted manure stimulated nitrification from the first. Fresh manure and straw at first inhibited nitrification until decompn. was well advanced. In a greenhouse bench soil to which KNO_3 was added reduction took place with fresh manure, straw and starch until a certain stage of decompn.; then nitrification commenced, but was checked by a second application of the organic materials. In a soil from the District of Columbia and one from Nevada to which peptone was added the original NO_3 content was reduced by cellulose, glucose and starch, and no nitrification took place until the glucose and starch had disappeared. With a productive Calif. soil to which KNO_3 was added, straw caused a reduction of NO_3 of 0.152 mg. per g., fresh manure 0.07 mg., cellulose 0.320 mg. and dextrose 0.699 mg. after 2 weeks. The loss of NO_3 was accompanied by a gain in organic N and there was some gain in total N. The only serious loss occurred with dextrose. With the productive Calif. soil and a District of Columbia soil to which no N was added green rye and vetch caused rapid nitrification accompanied by rapid decrease in organic N and a small loss in total N in both soils. Mature wheat straw caused a loss in total N. In an expt. with these 2 soils to which KNO_3 was added nitrification that was not so rapid took place in the controls and in the cases in which green manure was used. It is pointed out that in agricultural practise the plowing under of straw material in a decayed state or of green manures that have been allowed to mature serves to reduce the quantity of available N in the soil. When such practise is followed only during fall plowing, a sufficiently advanced stage of decompn. would be reached by spring so that interference with normal nitrification would not occur. Plowing under of green manures presents a different problem; these are readily attacked by saprophytic microorganism and rapid decay accompanied by vigorous nitrification takes place, thus maintaining a supply of available N.

J. J. SKINNER.

Austria-Hungary and the artificial fertilizer industry. H. G. *Chem. Ind.* 38, 239-41(1915).—A review.

F. W. SMITH.

Evaluation of methods for the determination of phosphoric acid which is soluble in citric acid and which is found in dephosphorization slags (Thomas slag). O. SICHMANN. *Russ. J. Exp. Landw.* 16, 160-212 1915.—A comparison of the molybdc method, the methods of Lorentz, Popp, Darmstadt, and Naumann, and the HCl method, shows very little difference among them. The method of Lorentz gave the lowest results. Tests with Na_2PO_4 show that ppts. obtained by the Lorentz method are pure. For speed and convenience, the methods of Popp and Lorentz are more advantageous, the latter method being the simpler.

W. H. FRY.

Tobacco: Influence of fertilizers on composition and quality. J. W. AMES AND G. E. BOLTZ. *Ohio Agr. Expt. Sta. Bul.* 385, 1-5-200 1915.— NaNO_3 causes a decrease, in most instances, in total ash, P, S and Cl. Of the essential elements present, Ca is found in largest amt. followed by N, K, Mg, S and P. The addition of CaO to the soil decreased the Ca and increased the Mg in the tobacco. A complementary relation exists between Ca and Mg when one is high the other is low. Tobacco from limed plots, as a rule contains less P, K and S than that from unfired plots. Relatively small amts. of P are removed by the crop as compared with other constituents which are regarded as less essential for plant growth. The highest percentage of N is found in tobacco from unfertilized soil. Organic N supplies more N to tobacco leaves than inorganic N. Tobacco from CaCl_2 or KNO_3 plots contains

larger amts. of K than from KCl plots fertilized with like quantities and carriers of P and N. NaNO_3 tends to increase the K content. KCl impairs the smoking test of cigars. Tobaccos with high Cl content had a black charred ash and held fire only $\frac{1}{2}$, as long as tobacco from plots treated with K_2SO_4 or KNO_3 . R. C. ROARK.

Experiments with fertilizers and manure on tobacco grown continuously and in rotation with wheat and clover. C. E. THORNE. Ohio Agr. Expt. Sta., *Bull.* 285, 210-21 (1915).—Detailed results are given in tables of the effect of different fertilizer treatments. R. C. ROARK.

The fertilization of peach orchards. W. H. ALDERMAN. West Virginia Agr. Expt. Sta., *Bull.* 150, 3-39 (1915).—Of the several single elements of plant food used, N gave the best results. K diminished development and in some cases killed the trees, while P in no way influenced either vigor or productiveness. The influence of CaO could not be definitely detd. R. C. ROARK.

The use of sprays rich in copper. E. RABATH. *Rev. vit.* 42, 377-81 (1915).—Gayon and Millardet have shown that 20-30 mg. CuSO_4 per 100 liters of water prevent growth of zoospores of mildew (of vines). R. recommends the following Denigé test for small amts. of Cu in soln. To 1 cc. powdered KBr add 1 cc. H_2O and shake till in soln. Then add to the cold soln. 2-3 cc. pure K_2SO_4 . To test for small amts. Cu, evap. 2-3 cc. of suspected soln. in an evapg. dish. To the residue add a drop of the above reagent. Cu is indicated by rose or carmine color. The reaction is specific. Com. sprays should be so tested because they are often colored with methylene blue and contain no Cu in soln. Molasses or glycerol added to neutral Bordeaux spray gives a larger amt. of Cu in soln. Casein or milk gives increased adhesion to leaves. R. recommends the following formula: 250 g. CuSO_4 added just before use, 250 g. NH_4OH , 60-80 g. casein dissolved in H_2O with sufficient CaO, 1 kg. molasses, all made up to one hecto. W. V. CRUICK.

The Martini copper-lime spraying solution. M. RIPPER. *Wiener Landw. Ztg.* 65, 331 (1915).—A great saving of CuSO_4 can be realized if Cu-CaO spraying solns. are made according to the Martini method in which one-half of the CuSO_4 is replaced by alum. The soln. which contains 0.4 CuSO_4 , 0.4 kg. alum, 0.5 kg. CaO and 100 l. H_2O , is prepared by first dissolving the alum and CuSO_4 in water and then adding CaO emulsion until an alk. reaction is obtained (either litmus paper or phenolphthalein as indicator). This soln. is stated to be just as effective as a 1% Cu-CaO soln. and has been used with excellent results both in Italy and Austria. The alum causes the soln. to cling to the leaves better. C. F. MILLER.

The amount of arsenic in solution when lead arsenate is added to different spray solutions. W. B. ELLETT AND J. T. GRISSOM. Virginia Agr. Expt. Sta., *Tech. Bull.* 8, 160-4 (1915).—Na and K sulfides dissolve more As when mixed with Pb arsenate than the commercial "Ca and Ba sulfur" spray solns. When Pb arsenate is added to either the summer strength of "Na sulfur" or of "K sulfur" a large % of As goes into soln. BaCl_2 retards the solubility of the As when added to Na and K sulfides. When Pb arsenate is added to the different sulfur spray solns. the amt. of As in soln. is increased. This accounts for the burning effect when used together as a spray. The As in soln. is in the form of sulfides, polysulfides, thioarsenate and arsenates of the diff. alkali metals present and when oxidized forms arsenates and arsenites. With Ca and Ba the As is less sol. than with Na and K. If mixts. with As are desired for spraying, Pb arsenate is less harmful than Paris green. Ba arsenate, when used with the diff. sulfur sprays, indicates that slight burning would take place with "Ca and Ba sulfur" and that the amt. of As in soln. is less than when used with water. With Na and K sulfides this substance would be harmful. R. C. ROARK.

Control of the cochylis and eudemis (insect pests of the vine). J. FREYLAND. *Rev. vit.* 42, 421-4(1915).—A Pb arsenite spray is prepd. by adding slowly a soln. of 900 g. $\text{Pb}(\text{OAc})_2$ in 75 l. water to 300 g. $\text{Pb}_2(\text{AsO}_4)_2$ in 25 l. water. A nicotine spray consists of 300 cc. of a 10% soln. of nicotine in 100 l. Bordeaux spray. W. V. CRUESS.

Rapid method of preparing sprays containing casein. V. VERMOREL AND E. DANTONY. *Rev. vit.* 42, 448(1915).—To 1000 cc. H_2O add 100 g. casein; mix with 1000 cc. $\text{Ca}(\text{OH})_2$ containing 50-200 g. CaO per l. The casein dissolves in a few minutes. Use 1000 cc. of this casein soln. per hectoliter of alk. spray to give increased spreading and adhesive power. W. V. CRUESS.

Influence of potash waste liquors on crops (HASELHOFF) 14.

Fertilizers. W. F. DOWNS. *Brit.*, 16,335, July 8, 1914. The phosphate content of natural phosphate rock is rendered available as a plant food by heating a mixt. of the finely divided rock and SiO_2 to a temp. below that at which P_2O_5 is evolved or sintering can occur, the amt. of SiO_2 being sufficient to unite fully with all the bases present in the rock. Generally, a temp. from 720 to 750° and not in excess of 1100° is desirable. The product is insol. in H_2O but is sol. in HCl and gives up a substantial proportion of the contained phosphate to a neutral soln. of NH_4 citrate.

Insecticides. WILKIE & SOAMES. *Brit.*, 15,765, July 1, 1914. A compn. for destroying insects, larvae, etc., consists of a mixt. of dried and powdered soap and S. Naphthalene and cresylic or carbolic acid may also be added. The mixts. may be employed in powder form or dissolved in H_2O .

Disintegrating superphosphate. H. HALL. *Ger.*, 284,580, Oct. 6, 1914. Constructional details of a chamber for this purpose.

16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Clarification of wines with milk. B. FALLOT. *Rev. vit.* 42, 407-8(1915).—One-half to 2 liters milk per hecto. of wine is very useful in bleaching rose colored wines or yellow wines. An objection to milk fining is that considerable lactose is left in the wine and may serve as food for bacterial diseases of wine. W. V. CRUESS.

"Sulfuring" crushed grapes. L. SEMICHON. *Rev. vit.* 43, 200-2(1915).—One kg. of S may be burned per hectoliter of space in the wine tank. Grapes may be crushed into this. The must will absorb about 75 mg. SO_2 per liter in this way, if the work is done carefully. The SO_2 checks wild yeasts and gives a cleaner fermentation than is possible without its use. W. V. CRUESS.

The production of wine from mildewed grapes. J. LARMEILLIERE. *Rev. vit.* 43, 193-6, 213-6(1915).—By judicious use of SO_2 and pure selected yeast, sound wines can be made from grapes attacked by mildew. Vineyards and grapes in France have become badly attacked by mildew this season. W. V. CRUESS.

Detection and estimation of phosphoric acid (MÄDINGER) 7. Utilization of sulfite waste liquors (KIBV) 23.

Rectifying spirit. C. SCHILLING. *Brit.*, 16,474, July 10, 1914. In rectifying spirit in periodically working app., the whole of the foreshots and faints obtained in 1 operation are distd. with the crude spirit in the next operation, so that in each operation the end products, namely ethers and fusel oil, are obtained. No faints of the 2nd

grade are obtained, the fractions collected being ethers, foreshots of the 3rd and 2nd grade, rectified spirit, faints of the 3rd grade, and fusel oil. (1) In treating crude spirit having a low content of aldehydes, the crude spirit is first put into the still and dild. The charge is heated, and, after the formation of vapors, the trays of the column are filled with foreshots of the 2nd grade. The foreshots of the 3rd grade are then admitted to the top of the column. The admission of H_2O to the condenser is then reduced, so that vapors flow to the cooler, ethers being thus obtained. The remainder of the foreshots of the 2nd grade is then run into the middle of the column, and ethers, foreshots of the 3rd and 2nd grade, and refined spirit are successively collected. A few hrs. before the end of the distn., the faints are run into the still or the bottom of the column, and the remainder of the refined spirit and the faints is successively obtained. The fusel oil may be afterwards distd. over. (2) In the case of crude spirit containing a large amt. of aldehydes, the process is modified by charging the still with H_2O which is heated till it boils, running preheated crude spirit rapidly into the top of the column, then running foreshots of 3rd grade into the top of the column, and the whole of the foreshots of the 2nd grade into the middle of the column. The crude spirit may, before distn., be treated with $K_2Mn_2O_7$ to destroy malodorous impurities and with alkali to neutralize acid and to decompose the ethers.

Purifying carbon dioxide. G. M. CLARK. *Brit.*, 12,165, May 16, 1914. CO_2 obtained in the brewing of beer is purified before returning to the cycle of operations, by washing the gas first with H_2O and then with permanganate soln., then drying the gas, and afterwards washing with concd. H_2SO_4 , and finally freeing the gas from acid particles by passage over an alk. substance. The vessels used in the successive washings are each provided with a bell into which the gas is passed and which dips into the washing liquid, the bell being provided with means for breaking up the bubbles of gas. Thus the washing liquor is contained in a closed vessel, and gas is introduced through a bell resting on the bottom of the vessel and provided at its lower edge with notches and on its exterior with superposed and inclined perforated flanges for breaking up the bubbles of gas. Gas passes from the closed vessel containing the washing liquor through the upturned end of a pipe leading into the upper portion of one of the washing vessels.

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

Pharmacopeia Fennica v. F. DIETZE. *Apoth. Ztg.* 30, 305-7, 312-4, 322-3 (1915).—A discussion of some of the more important changes contained in the new edition. W. O. E.

Testing ext. condurango fl. and cortex condurango. ERNST RICHTER. *Apoth. Ztg.* 30, 330(1915).—Reference is made to Ger. Pharm. prepn. W. O. E.

The pneumatic filling of ampoules. ERNST RICHTER. *Apoth. Ztg.* 30, 338-9 (1915). W. O. E.

Evaluation of insect powder. G. FROMME. *Apoth. Ztg.* 30, 405-6(1915); cf. Kurt Trottner, *C. A.* 8, 1325.—As the result of recent expts., it would appear that no marked relationship exists between the number of pollen grains present in the sample and its toxicity. W. O. E.

The conversion of hydroacridine into acridine. J. BOGS. *Apoth. Ztg.* 30, 406-7 (1915).—Oxidation with H_2SO_4 was employed, the best results being obtained by heating at 100° with 78% H_2SO_4 . W. O. E.

Studies on mace. A. TSCHIRCH AND H. SCHKLOWSKY. *Univ. Bern. Arch. Pharm.* 253, 102-9(1915).—The finely powdered material was exhausted in rotation

with petr. ether, alc., CHCl_3 and H_2O . The first named solvent yielded a brownish oil which on cooling and freezing gave the monobasic *macilenic acid*, $\text{C}_{14}\text{H}_{20}\text{O}_2$, needles, m. 70° , difficultly sol. in cold, easily sol. in hot alc., in CHCl_3 , benzene and Et_2O , difficultly sol. in cold, more readily in hot chloral hydrate soln. It forms the *silver salt*, $\text{C}_{14}\text{H}_{18}\text{O}_2\text{Ag}$, likewise a *barium salt* difficultly sol. in H_2O and alc. The acid possesses a double bond and is monocarboxylic; it belongs to the oleic acid series. This is the first time an acid of this type has been isolated from plant sources. On treating the oil, from which the above acid was separated, with steam for a week in the presence of KOH , 2 layers gradually formed in the flask, the upper being the alkali-insol., the lower the alkali-sol. portion. Only from the former could a cryst. substance be sepd., namely an acid m. 65° and having the formula of myristinic acid, $\text{C}_{14}\text{H}_{28}\text{O}_2$. Attempts to detect glycerol in the oils extd. by petr. ether were negative, hence the conclusion that mace contains no true fat or glycerol ester. On distg. *in vacuo* the oil freed from macilenic acid, *macilolic acid*, a hydroxycarboxylic acid, $\text{C}_{20}\text{H}_{30}\text{O}_3$, was isolated from the highest boiling portion in the form of scales m. 68° . The *silver salt*, $\text{C}_{20}\text{H}_{28}\text{O}_3\text{Ag}$, and *potassium salt*, $\text{C}_{20}\text{H}_{28}\text{O}_3\text{K}$, were both prepd. The acid is sol. in cold chloral hydrate soln. Boiling alc. exts. considerable yellow coloring matter together with a colorless substance m. $76-7^\circ$, likewise a wax-like substance, which on hydrolysis with alc. KOH yielded a colorless cryst. compd. carbonizing at 300° . The CHCl_3 ext. gave crystals m. 131° and showing all the reactions of the phytosterols. In addition, a reddish yellow coloring matter was isolated in pure form, the spectrum of which was similar to that of xanthophyll. Both cold and hot H_2O yielded yellowish solns. containing amylopectin starch precipitable by alc. and having the compn. $6(\text{C}_6\text{H}_{10}\text{O}_5) \cdot 2\text{H}_2\text{O}$.

Hematoxylin as indicator in volumetric alkaloidal determinations. Evaluation of cinchona bark. G. FRERICHS AND E. MANNHEIM. *Arch. Pharm.* 253, 117-35(1915).—The conclusions arrived at are summarized as follows: (1) The indirect titration of cinchona alkaloids with freshly prepd. hematoxylin soln. as indicator according to the Ger. Pharm. is impossible. (2) Indirect titration of cinchona alkaloids with hematoxylin soln. containing hematein is unreliable. (3) Direct titration of cinchona alkaloids with 0.1% HCl and freshly prepd. or old hematoxylin soln. as indicator is simpler and more certain than the indirect titration. (4) The addition of Et_2O in the direct titration according to Fromme is superfluous and impracticable. (5) A 1:100 soln. of hematoxylin in alc. is recommended. (6) The evaluation of cinchona bark according to the Ger. Pharm. yields much too low results on account of incomplete extn. of the alkaloids. (7) Fromme's procedure (preliminary treatment of the bark with aq. HCl) is simple and dependable. (8) Gaze's modification of the Pharm. procedure (decrease in the quantity of bark and addition of alc.) may yield lower values in barks of high alkaloid content than would result with Fromme's procedure. (9) The tedious Pharm. method for purifying the alkaloids is superfluous. The crude alkaloid isolated according to Fromme can be titrated directly without previous purification.

Determination of the solidification point of fatty acids and its importance in judging cacao butter. P. BOHRISCH AND F. KUERSCHNER. *Pharm. Ztg.* 60, 361-2(1915). W. O. E.

The botanical source, physical characters, and chemical constituents of chaulmoogra oil. FREDERICK B. POWER. *Am. J. Pharm.* 87, 493-500(1915).—A severe criticism of the paper by Chattopadhyaya (*C. A.* 9, 3117). P. emphasizes the statement that chaulmoogra (*Taraktogenos*) oil and gynocardia oil are totally unlike both in their physical characters and chem. compn. Along with data establishing the authenticity of his oils, P. gives the following: *Physical characters*: (1) chaulmoogra oil: soft solid at ordinary temp., m. $22-3^{\circ}$, d_{25} 0.951 and d_{45} 0.940, $[\alpha]_D^{15} + 52.0^{\circ}$, acid value 23.9, sapon. value 213.0, I value 103.2. (2) Gynocardia oil: pale yellow liquid at ordinary temps., odor resembling that of linseed oil, d_{25} 0.925, acid value 4.90, sapon. value 197.0, I value 152.8. *Chemical composition*: (1) chaulmoogra oil: (from the seeds of *Taraktogenos Kursii*, King), optically active, consists, to a large extent, of the glyceryl esters of optically active acids of an entirely new type, represented by the general formula $C_nH_{2n}-O_2$, having a cyclic structure. The acid present in the largest proportion possesses the formula $C_{11}H_{20}O_2$, m. 68° , $[\alpha]_D + 56^{\circ}$, and has been designated *chaulmoogric acid*, while a lower homolog, $C_{10}H_{18}O_2$, m. 60° , $[\alpha]_D + 68^{\circ}$, has been termed *hydnocarpic acid*, on account of having first been isolated from a hydnocarpus oil (*J. Chem. Soc.* 87, 888(1905)). Both of these acids are beautifully cryst. substances, from which a number of derivs. have been prepd., and their constitution has also been definitely established (*C. A.* 1, 1561, 2114). Inasmuch as acids of the above described type had hitherto not been known to occur in a fatty oil, they have been classified by Lewkowitsch ("Chemical Technology and Analysis of Oils, Fats and Waxes") under the heading of "the chaulmoogric acid series." Chaulmoogra oil contains, furthermore, a relatively small proportion of palmitic acid and a phytosterol. (2) Gynocardia oil (from the seeds of *Gynocardia odorata*, R. Br.) is completely devoid of optical activity, contains none of the members of the chaulmoogric acid series, and has been shown to consist of the glyceryl esters of the following acids: (cf. *J. Chem. Soc.* 87, 896-900(1905)); (1) linolic acid, or isomerides of the same series, constituting the largest proportion of the oil, (2) palmitic acid, in considerable amt., (3) linolenic and isolinolenic acids, the latter preponderating, and (4) oleic acid, in relatively small amount. A phytosterol, m. 133° , was also isolated. Both the physical properties and chem. compn. of the above mentioned oil render it evident that the chaulmoogra oil of European commerce could never have been obtained from *Gynocardia* seeds. On the other hand, representative samples of commercial chaulmoogra oil have been found to agree closely in character with the oil expressed from genuine *Taraktogenos* seed, thus completely confirming, from the chem. side, the botanical observations of Prain (*Pharm. J.* 64, 522(1900); 66, 596(1901)) with respect to the source of chaulmoogra oil. *Gynocardia* seeds contain, besides the fatty oil, the cryst. cyanogenetic glucoside, gynocardin, $C_{12}H_{19}O_5N$, which has likewise been made the subject of a complete chem. investigation (*J. Chem. Soc.* 87, 349-57(1905); 97, 1285-9(1910)). P. also notes that the total compn. of chaulmoogra oil, as given by Chattopadhyaya, is equal to 110%, which is obviously an error. W. G. GAESSLER.

A comparison of the guinea-pig and cat methods for the physiological standardization of aconite preparations. J. C. FORD, C. P. S. FORD AND J. E. WINE. *Am. J. Pharm.* 87, 489-92(1915).—A discussion of the methods of assay used with the following

conclusions: (1) The chem. method of assay for aconite is unreliable. (2) The taste and frog methods for the physiol. testing of aconite have little to recommend them. (3) The guinea-pig method and the cat method give results that are fairly concordant.

W. G. GAESSLER.

So-called concentrated solution of silver iodide. JOHN K. THUM. *Am. J. Pharm.* 87, 500-1(1915).—T. recommends the following formula: AgNO_3 , 3.7 g., KI 17.0 g., distd. water ad 25.0 mils. This vol. of 25 mils soln., when added to 75 mils distd. H_2O , makes a 5% suspension of AgI .

W. G. GAESSLER

Stearic acid as a coating for enteric pills. WILLIAM G. TOPLIS. *Am. J. Pharm.* 87, 518-20(1915).—T. recommends stearic acid as a coating to render enteric pills insol. in the stomach and describes method of coating.

W. G. GAESSLER.

Effect of storage on the moisture content of cloves. A. W. OGDEN. *Am. J. Pharm.* 87, 526-7(1915).—Samples of whole cloves were taken from original unbroken bales after arrival in this country and stored in ordinary wooden spice boxes in a dry storeroom in New York City. Gross weighings were made at intervals and as these showed a gradual loss, the expt. was continued and careful net weighings were made after periods of 6 months and 54 months. A table is given showing analyses and the av. losses for the periods specified. The av. loss on all samples for the 6 months' period was 2.42% and for the 54 months' period 4.70%; the max. loss for this latter period was 7.83%.

W. G. GAESSLER.

Tincture of opium (laudanum). A. MCGILL. Inland Revenue Dept., Ottawa, Can., *Bull.* 315, 15 pp.(1915).—Analyses are given of 127 samples collected in Canada. Of these 96 met the demands of the Brit. Pharm.

Glycobromine. ANON. *Boll. chim. farm.* 54, 263(1915).—This compd. is the glyceride of the dibromide of cinnamic acid and contains 50% of Br ; it is a white, amorphous, tasteless powder, m. $66-8^\circ$, and is insol. in H_2O , slightly sol. in alc. and more sol. in Et_2O and CHCl_3 . It may be used as a substitute for the common bromides.

H. S. PAINE.

Method of determination of proteolytic enzymes. BICE NEPPI. Milan. *Boll. chim. farm.* 54, 289-97(1915).—After considering the various methods which have been proposed N. concludes that the Fuld method (detn. of the minimal amt. of enzyme prepn. which is capable of effecting the proteolysis of 2 cc. of a 1% edestin soln. in $N/300$ HCl so that, after 15 min., no turbidity is produced by the addition of a 30% NaCl soln.) is the most suitable method for controlling the strength of pepsin preps. and should replace the method of the Italian Pharmacopeia. The Gross method of detg. the minimal amt. of enzyme prepn. which is capable of effecting the proteolysis of 10 cc. of a 1% casein soln. in 1% Na_2CO_3 so that, after 30-40 min., no turbidity is produced by a 5% hydro-alc. soln. of AcOH , with slight modification, is recommended for displacing the present method of the Italian Pharmacopeia for the detn. of the strength of pancreatin preps.

H. S. PAINE.

Iodated cotton containing approximately four per cent of free iodine. E. BOURQUEROT. *Boll. chim. farm.* 54, 390(1915).—Twenty-five g. of cotton dried at 30° are uniformly sprinkled with 2 g. finely powdered I and placed in a glass vessel provided with a ground glass stopper; this vessel, after being securely closed, is immersed to the neck in boiling H₂O for 2 hrs. The cotton is then preserved in closed containers; no decrease in content of free I was observed after 3 mos.

Progress and novelties of the pharmaceutical chemical industries in 1914. J. BOES AND H. WEYLAND. *Chem. Ind.* 38, 107–21, 146–65(1915).—A review.

F. W. SMITHER.

The caffeine content of various beverages. JOHN L. HENDERSON. *Carolina J. Pharm.; Midland Druggist* 49, 348–9(1915).—The following amts. of alkaloid were found: Coffee No. 1, in 160 cc. 0.0287 g. No. 2, in 165 cc. 0.0174 g., No. 3, in 190 cc. 0.0372 g. caffeine. Tea, in 180 cc. 0.0176 g. theine, "Coca-cola," in 190 cc. 0.0371 g., "Pepsi-cola," in 193 cc. 0.0278 g. caffeine or allied substance. Chocolate, in 158 cc. 0.0195 g. theobromine. The results are also shown graphically and indicate that each cup or glass of these beverages contains alkaloid equiv. to $\frac{1}{5}$ – $\frac{1}{4}$ of the therapeutic dose. In excessive use, the alkaloids cause nervousness, and tannin and caffeine cause gastric disturbances.

S. WALDBOTT.

Preparing argyrol solutions. ROBERT W. TERRY. *Midland Druggist* 49, 347 (1915).—To avoid formation of a large lump, rapidly powder weighed argyrol in a dry mortar and add a small amt. of H₂O at once with rapid trituration. Pour off soln. and add to the residual small lump more H₂O in small amt. Solns. up to 50% may thus be prepared.

S. WALDBOTT.

Stability of lime water. ROBERT W. TERRY. *Midland Druggist* 49, 406–7(1915).—Filtered lime water left in a corked bottle, changed only from 0.1649 g. to 0.1614 g. Ca(OH)₂ in 10 days. Lime water containing undissolved Ca(OH)₂, a caustic irritant, should never be dispensed.

S. WALDBOTT.

The accuracy of fermentation saccharometers. ROBERT W. TERRY. *Midland Druggist* 49, 407–8(1915).—Four series of detns. of glucose (1%, 0.75, 0.5 and 0.25%) were made with 5 Hg-seal fermentation instruments. The fermentation temp. of 90° F. was maintained by means of a const. temp. water bath heated by elec. light globes. The percentages indicated were practically fully recovered. The method is preferable to that with Fehling soln.

S. WALDBOTT.

Unguentum iodoformi. Brit. Pharm. 1914. D. F. RITCHIE. *Pharm. J.* 95, 539(1915).—Prepared lard directed by the new pharmacopeia in the prepn. of this ointment develops after a week free fatty acids, causing decompn. of CHI₃ and browning of the ointment due to free I. The paraffin base of the former pharm. gives a pharmaceutically sound prepn.

S. WALDBOTT.

Influence of fertilizers on tobacco (AMES) 15.

Therapeutic compounds. R. WOLFFENSTEIN. Brit., 16,585, July 11, 1914. Hydroxyquinoline salicylic esters or derivs. thereof are obtained by the reaction of a chloride of salicylic acid or a homolog or deriv. thereof upon hydroxyquinolines. The production of the salicylic and acetoxybenzoic esters of 8-hydroxyquinoline is described in examples. The products have therapeutic properties, as they affect the metabolism of purines.

Enzymes; toxins. A. BORDIN and J. EYFRONT. Brit., 16,198, July 7, 1914. Enzymes and toxins are prepd. by cultivating aerobic bacteria in contact with air in thin layers of a mash rich in nitrogenous constituents and poor in carbohydrates, formed of vegetable or animal albuminoid materials, such as casein, fibrin of maize, soy-cake, from which the fat has been extd., or bran or other vegetable waste product which has been freed from carbohydrates by saccharification, fermentation, and distn. The mash prepd. in a boiler is forced by air pressure into a sterilized culture chamber formed of materials such as Al, enamelled metal, porcelain, or glass, which do not affect bacteria. The mash is distributed in thin layers on trays mounted on a central shaft, which is rotated either with a to-and-fro motion to agitate the mash or rapidly to discharge the trays by centrifugal action. Either a sep. culture is added to the mash, or portions of a previous culture are left on the trays. The culture chamber is retained at 30-40°, and air sterilized by passage through a filter is passed through the chamber. The culture may also be made in a chamber with fixed plates, or filled with pumice-stone, coke, shavings, etc. Starch-liquefying enzymes are obtained from bacteria of the species *tyrothrix* or *subtilis*, and toxins from the bacilli of diphtheria, tetanus, or tuberculosis. The cultures may be preserved by the addition of sea-salt, $MgSO_4$ (dihydrogeraniol), or $(NH_4)_2SO_4$ or $HCHO$. The soln. may be concd. *in vacuo*. The enzyme or toxin may be pptd. by addition of a large quantity of $(NH_4)_2SO_4$.

Catalytic hydrogenation. C. PAAL. Brit., 16,180, July 7, 1914. Alcs., aldehydes, and acids of the olefinic terpene series are hydrogenized by treatment with H in the presence of a metal or protohydroxide of the Pt group, preferably deposited upon a finely divided support. In this manner, citral, geraniol, and linalool are converted into dihydro and also into tetrahydro derivs. The process may be carried out at ordinary or increased pressure. The phenylurethan of dihydrolinalool melts at 60° and the semicarbazone of dihydrogeraniol at 112-113°.

Methyl chloride. B. S. LACY. Brit., 16,194, July 7, 1914. $MeCl$ is prepd. by mixing Cl with a large excess of CH_4 and exposing the mixt. to an elevated temp. in a suitable reaction vessel: a temp. of about 400° is suitable. The reaction vessel is preferably a tube of glass, quartz, porcelain, earthenware, etc. Bone-black or other forms of C, or other material, may be used as a catalyst in the reaction. The resulting mixt. of gases is passed through an absorbent, preferably H_2O , to remove HCl , then dried, then subjected to cold and pressure to liquefy the $MeCl$ and other chlorides of CH_4 , formed while unused CH_4 is recovered for re-use.

***o*-Acetoxybenzoates.** O. GERNGROSS and H. KAST. Brit., 25,080, Nov. 3, 1913. An aq. soln. or suspension of *o*-acetoxybenzoic acid is treated with a suitable metallic compd., filtered, the resulting soln. concd., preferably under reduced pressure, and the sepn. of the salt completed by addition of an org. precipitant, such as acetone, alc. mixed with ether or acetone or both, or alc. mixed with a hydrocarbon such as ligroin or benzene; the sepd. salt is finally washed with ether, etc. Preferably, such metallic compds. are used as have an acid component which does not decompose the acetoxybenzoates and also prevents or limits injurious action of the base upon the free acid; such compds. are, e. g., water-glass or other metal silicate produced by interaction of water-glass and a metallic salt such as $CaCl_2$. According to examples: an aq. suspension of acetoxybenzoic acid is treated with $NaHCO_3$, the filtered liquid

is evapd. under reduced pressure, and the sepn. of the Na salt is completed by addition of acetone; an aq. suspension of the acid is treated with water-glass soln., pptd. silicic acid is filtered off, and the soln. further treated as above; or the silicic acid may be removed by addition of alc. and filtering. Zn or Hg salts can also be obtained by the process. Cf. *C. A.* 9, 1225.

Esters of tertiary alcohols. NEUMANN & CO. CHEM. FABRIK GES. and J. ZELTNER. Brit., 25,262, Nov. 5, 1913. For the process see *C. A.* 9, 1370. The production of the valerate, cinnamate, benzoate, *p*-nitrobenzoate, and acetate of tertiary amyl alc. is described in examples; the cinnamate yields a dibromo addition product; the *p*-nitrobenzoate on reduction gives the *p*-aminobenzoate.

Pyrrolidine derivatives. CHEM. FABRIK AUF ACTIEN V. E. SCHERING. Brit., 25,805, Nov. 11, 1913. An acylpyrrolacemic acid ester is condensed (1) with benzaldehyde and a nuclear substituted aniline, or (2) with a substituted benzaldehyde and aniline or a nuclear substituted aniline, or (3) with benzaldehyde and a pyrazolone or quinoline deriv. containing a primary amino group, or (4) with a heterocyclic aldehyde and aniline or a nuclear substituted aniline, or with a pyrazolone or quinoline deriv. containing a primary amino group. As substituted benzaldehydes, piperonal and *p*-dimethylaminobenzaldehyde are suitable, and as derivs. of aniline are indicated toluidines and anisidines.

Chlorohydrocarbons. CASSELLA & Co. Brit., 16,317, July 8, 1914. Tetrachlorotoluene is obtained by chlorinating toluene in the presence of anhydrous FeCl₃ or Fe. Tetrachlorobenzal chloride is obtained by chlorinating tetrachlorotoluene at temps. considerably below b. p., preferably at 100–130°, in the presence of light or ultraviolet rays.

Ethers; hydrocarbons. G. BOITREAU. Brit., 15,806, July 2, 1914. Ethylidene-glycol ethers are obtained by the reaction of C₂H₂ on OH compds., particularly alcs., in the presence of catalysts such as Hg salts. *E. g.*, MeOH is treated. Unsatd. hydrocarbons are obtained by dehydrating the ethers specified above. The dehydration may be effected by passage through a heated tube containing oxides, such as SiO₂, Al₂O₃, Ca or Mg silicates, argillaceous earths, or kaolin, phosphates, *e. g.*, of Al, Ca, or Mg or sulfates, such as those of Al, Ba, or Ca. Examples are given of the production of butadiene.

Aldehydes; carboxylic anhydrides; hydrides; esters; ethers. G. BOITREAU. Brit., 15,919, July 3, 1914. In carrying out the reaction of C₂H₂ upon H₂O, alcs., carboxylic acids, or hydroxy or carboxylic compds. generally, in the presence of a catalyst, the catalyst is formed in the substance treated. This may be effected by dissolving in the substance treated a slightly acid Hg salt, such as the acetate, or HgO, and then adding H₂SO₄ to form the sulfate. According to an example, HgO is dissolved in HOAc, H₂SO₄ is added, and then C₂H₂ is introduced; or a mixt. of H₂SO₄ and HOAc may be added to the soln. of HgO in HOAc. The production of Ac₂O and ethylidene diacetate is referred to.

Organometallic compounds. FARBW. v. M. L. & B. Brit., 15,950, July 3, 1914. Organoarsenic compds. are obtained by combining diazo compds. with derivs. of 3,5-diaminoarylarsinic acids substituted in the 4-position, or reduction products thereof. Products are specified from the following pairs of components: *p*-nitroaniline and 3,4,5-triaminophenylarsinic acid; aniline and 3,5,3',5'-tetraamino-4,4'-dihydroxyarsenobenzene; sulfanilic acid and 3,4,5',3',4',5'-hexaaminoarsenobenzene. The products have therapeutic properties. 3,4,5-Triaminophenylarsinic acid is obtained by reducing 3,5-dinitroarsenilic acid with FeSO₄ soln. in the presence of NaOH lye.

Acid chlorides. A. HOCHSTETTER. Ger., 283,896, Aug. 17, 1913. COCl₂, to-

gether with vapors of organic acids (chloroacetic acid), are conducted through a heated reaction chamber charged with porous bodies as contact substance. The yield is quant., and technical difficulties are eliminated.

Acid chlorides. A. HOCHSTETTER. Ger., 284,617, Aug. 17, 1913. One mol. of the alkali salt is heated in a closed vessel with at least 1 mol. of COCl_2 (for each carboxylic group present). E. g., 8.2 kg. anhydrous NaOAc are heated with 10 kg. COCl_2 in the autoclave at 120° , with continuous removal of the resulting CO_2 . After cooling and removing the residual CO_2 , almost pure AcCl , in a nearly quant. yield, is obtained upon condensing the vapor passing off with the CO_2 by strong cooling.

Salicyl chloride. R. WOLFFENSTEIN. Ger., 284,161, Dec. 20, 1911. Addition to 277, 659 (C. A. 9, 514). Salicylic acid is allowed to react, in the heat, preferably at the b. p. of the reaction mixt., upon SOCl_2 dissolved preferably in benzene or other indifferent organic solvent. The action is allowed to proceed until no more HCl and SO_2 are evolved.

Condensation products containing nitrogen. FARBW. v. M. L. & B. Ger., 284,291, Oct. 16, 1913. To obtain these products diarylamines or the corresponding carbazole derivs. are heated with epichlorohydrin to high temps. They serve for the manuf. of new dyes and also for pharmaceutical purposes.

Dihydric phenols and substitution products. C. F. BOEHRINGER & SÖHNE. Ger., 284,533, Mar. 15, 1912. Addition to 269,544 (C. A. 8, 2221). Dihydric phenols and their substitution products, such as the sulfonic and carboxylic acids, may be obtained from the corresponding dihalogen substitution products of aromatic hydrocarbons or their sulfonic and carboxylic acids, by heating these compds. under pressure with aq. alkali hydroxides or alkali carbonates in the presence of Cu or Cu salts as catalyzers. The process marks a material technical advance, and gives high yields.

Hydroxyanthrapyridones. FARBW. v. M. L. & B. Ger., 284,209, Oct. 18, 1913. Arylsulfonacetyl compds. of α -aminoanthraquinone are heated with alkali. The reaction proceeds smoothly.

Dry cultures of bacteria. R. MARCUS. Ger., 283,882, Mar. 8, 1913. The bacterial dry cultures obtained heretofore with the employment of starch or milk sugar have the disadvantage that the absorptive material (starch, milk sugar) cannot be rendered sufficiently sterile, so that the products are never pure cultures. Perfectly pure dry cultures may be obtained by this process with the aid of amorphous silicic acid which is easily sterilized and chemically unalterable. Undild. bacteria cultures can be preserved by the amorphous silicic acid, without weakening their activity. The silicic acid can be sterilized thoroughly by heat, and rendered anhydrous, since it is stable even at temps. of 600° . Furthermore, its insoly. in H_2O is an advantage, as is also its low sp. gr. In preparing the culture, the organisms or bacteria cultures, grown on suitable media or in liquid media, are ground up in a sterile mortar with purest amorphous sterilized silicic acid. Silicic acid obtained in the elec. osmotic way is preferred. Silicic acid is added equal to about 50% of the wt. of the pure cultures.

Adhesive. J. MENSIK. Aust., 9,409, Nov. 5, 1913. Pulverized resin is treated with salicylic acid or its salts.

Sulfuric acid. M. SRECK. Brit., 16,187, July 7, 1914. The walls of H_2SO_4 chambers, etc., are supported by horizontal strips, tubes, etc., freely suspended by hooks. Flaps hooked on to or passed round the strips serve to secure these to the walls, and the strips are employed in short lengths to give freedom of movement to the walls of the chamber.

Sulfuric acid. F. CURTIUS & Co. Brit., 28,550 Dec. 10, 1913. The SO_2 gases are introduced into the first tower of the system when cold or at a temp. considerably lower than 250-300°, which is that usually employed. The method is particularly advantageous when using roaster gases, as it is not necessary to reheat them after they have been cooled by the necessary purification. The lower temp. allows the first tower to be packed with coke, and it is advisable to make this tower larger than usual and to supply it with acid containing only a small amt. of HNO_3 or nitrosulfonic acid. For this purpose, the first tower may be fed exclusively with the acid from the producing towers, and not with acid from Gay-Lussac towers.

Sulfur dioxide. A. BAMBACH. Brit., 3,174, Feb. 6, 1914. Sulfates such as those of Ba, Ca, or Sr are raised to a red heat by burning among the broken material a

mixt. of gas and air. A hood is applied to the kiln as soon as SO_2 is evolved. The reaction is completed either by continuing the supply of gas and air, an excess of air being finally admitted to produce an oxidizing flame for destroying the sulfide which has formed, or by supplying only gas, *e. g.*, water-gas, until the reaction is completed, after which only air is introduced. Sulfides may also be treated in a similar manner, only gas with excess of air, or air alone, being supplied to the red-hot material. When a volatile oxide is obtained, such as ZnO from blende, a settling chamber is necessary; when BaO is formed, arrangements are provided for drawing it off in the fused condition.

Synthesis of ammonia. M. PIER. Brit., 213, Jan. 3, 1914. Catalytic agents are employed consisting of Ir or Rh or their compds., either singly or together, and a contact carrier of an alk. or basic nature, the amt. of carrier being a multiple of that of the catalytic metal, etc. *E. g.*, Rh or Ir chloride is pptd. with alkali, the ppt. mixed with an oxide or carbonate of an alkali or alk. earth metal, such as K_2CO_3 or MgO , and the product dried; or the soln. of the chloride may be applied directly to the contact-carrier; or Cr_2O_3 , obtained by heating H_2CrO_4 , is satd. with Rh chloride, and the product dried.

Synthesis of ammonia. M. PIER. Brit., 214, Jan. 3, 1914. A catalytic agent is spread on or distributed through a support or contact carrier of MgO or MgCO_3 . The MgO or MgCO_3 may be used together with other supports; but in all cases the amt. of MgO or MgCO_3 is a multiple of that of the catalytic agent. The catalytic agents used may be the metals of the Pt group, or Fe, Ni, Co, Mo, W, or U, or compds. of these metals, *e. g.*, $\text{Fe}_3(\text{OH})_8$, K ruthenate, Ru oxide or hydroxide or chloride, or mixts. of the last mentioned substance with Ir or Rh chlorides.

Ammonia. F. W. DAFERT and R. MIKLAUZ. Brit., 16,597, July 11, 1914. NH_3 is obtained by treating Ba_3N_2 with H, forming an intermediate compd. $\text{Ba}_3\text{N}_2\text{H}_4$, which on further treatment with H gives NH_3 and BaH_2 . The BaH_2 is converted into nitride by means of N at a higher temp. By periodically varying the temp., the reaction can be conducted with a mixt. of H and N.

Titanium oxide. P. FARUP. Brit., 15,680, June 30, 1914.

Alumina; alkali aluminates. M. BUCHNER. Brit., 15,854, July 2, 1914. Clay or like material containing Al or AlN is treated with strong or dil. acid such as H_2SO_4 , and the salt soln. obtained is pptd. by NH_3 soln. or by gaseous NH_3 , which may be obtained by treating AlN with H_2O ; or gases such as coke-oven gas or Mond gas containing NH_3 , or by a basic NH_3 deriv. The mixt. of Al_2O_3 and $\text{Fe}_3(\text{OH})_8$ is treated with an alkali such as soda lye, and the Al_2O_3 is then recovered from the aluminate soln. by auto-pptn. To make the original filtration easy, the Al salt soln. should be strong, and the NH_3 should be in excess. Alternatively, when a trace of Fe may be left in the product, the original soln. may be treated with $(\text{NH}_4)_4\text{Fe}(\text{CN})_6$ or other ferrocyanide, and the $\text{Fe}_4[\text{Fe}(\text{CN})_6]_3$ filtered off and treated with NH_3 for the production of $(\text{NH}_4)_4\text{Fe}(\text{CN})_6$ for re-use, the purified Al salt soln. being then pptd. with NH_4OH , etc., as before, the alkali treatment being omitted. The aluminous material used may be first converted into AlN .

Chromium and iron chlorides. BADISCHE. Brit., 29,325, Dec. 19, 1913. Cr ores, such as Cr ironstone, are heated with gaseous HCl or Cl and with a reducing agent such as coal, coke, or CO , the products being sepd. by volatilization. When HCl is used, the FeCl_3 volatilizes and the Cr_2Cl_6 is dissolved out of the mass with H_2O ; when Cl is used, both chlorides usually volatilize, the Cr_2Cl_6 depositing on the cooler parts of the app. In examples, Cr ironstone and coke are heated in a current of HCl ; and Cr ironstone is heated in a current of CO and Cl until Fe_2Cl_6 is no longer evolved,

whereupon sol. impurities are extd. with H_2O and the Cr_2Cl_4 is extd. in any suitable way.

Ammonium sulfate. BADISCHE. Brit., 27,962, Dec. 4, 1913. Ammonium sulfate is prepd. by the reaction of $(NH_4)_2CO_3$ or NH_4HCO_3 with $CaSO_4$ in the presence of H_2O , and is filtered from the pptd. $CaCO_3$ by immersing in the suspension a filter consisting of a hollow frame or box with 1 or more permeable sides and provided with means for placing the interior of the filter under reduced pressure; the $(NH_4)_2SO_4$ soln. is thus drawn off, while the $CaCO_3$ sets in a layer on the outside of the filter and is subsequently washed thereon with H_2O while the reduction of pressure in the interior of the filter is maintained. In carrying out the reaction, the $(NH_4)_2CO_3$ or NH_4HCO_3 may be employed as such, or gaseous NH_3 and CO_2 may be passed into a tower, down which an aq. suspension of $CaSO_4$ is allowed to trickle. Cf. C. A. 9, 1834.

Hydrogen. BADISCHE. Brit., 27,963, Dec. 4, 1913. A mixt. of CO and steam is passed over a mixt. containing a catalytic agent and a body which promotes the activity of the catalytic agent. Suitable catalytic mixts. consist of Fe, Ni, or Co, or oxides thereof, mixed with O compds. of Cr, Th, U, Be, or Sb; Fe mixed with less than its wt. of Ni; Fe_2O_3 of low activity coated with finely divided Fe_2O_3 prepd. at a low temp.; or Zn, Pb, Cu, V, Mn, or Ti, together with a promoter. The efficiency of a given substance as a promoter may be detd. by carrying out parallel tests with the catalyst with and without the substance in question. The contact masses may be in powder, porous lumps, etc., and binders, carriers, etc., may be added. The production of H is preferably effected at temps. not exceeding 600° . Any suitable gas mixts. may be used, and the bulk of the CO may be first removed therefrom catalytically, or otherwise, if desired; H_2S , etc., may be previously removed by means of Cu, etc. The presence of Cl, P, B, or Si in the catalytic mixt. should be avoided, if necessary. The following examples of the prepn. of the catalytic mixts. are given: a mixed soln. of ferric and Cr nitrates, with or without Al nitrate, is pptd. by NH_4OH , and the hydroxides are filtered off and pressed into suitable shapes; a mixt. of ferric nitrate, NH_4 chromate, and Th nitrate, is heated to give the oxides; a mixed soln. of ferric nitrate, Ni nitrate, and Cr nitrate is pptd. by K_2CO_3 , and the ppt. is filtered, washed, shaped, and dried; Fe_2O_3 produced at a high temp. is mixed with moist $Fe_2(OH)_6$, made into lumps, and dried; fine-meshed Fe wire netting is treated with ferric nitrate soln., and heated to decompose the nitrate; Cr, Ni, or Al nitrate may also be added; ZnO is mixed with Cr nitrate and heated to decompose the nitrate; Cr nitrate or acetate is pptd. by NH_4OH , the hydroxide is mixed with pptd. ZnO, shaped and dried; BeO may also be used; a mixt. of $Pb(NO_3)_2$ or $Pb(OAc)_2$ and $UO_2(NO_3)_2$ soln. is pptd. with NH_4OH , the ppt. is filtered, made into lumps, and heated; Cu and Zr nitrate soln. is pptd. by Na_2CO_3 or K_2CO_3 , filtered, the alkali salt washed out partly or completely, and the product molded and dried; mixts. of oxides of Mn and Cr, Ti and Sb, V and Cr, or Cr and Th, are also suitable; Al_2O_3 , alkali carbonates, etc., may be added as binding-agents or promoters; a soln. containing Ce and Cr nitrates is pptd. with NH_4OH , the ppt. filtered off, partly dried, made into a paste, shaped, and dried; other rare-earth salts may replace the Ce nitrate.

Hydrogen. J. PINTSCH, AKT.-GES. Brit., 28,904, Dec. 15, 1913. In mfg. H from ferruginous material by alternate oxidation with steam and reduction, briquets are employed for lining and building the reaction chambers, which are composed of oxides or carbonates of Fe, together with oxides or carbonates of such metals as do not form hydroxides in contact with H_2O , particularly Mg, Ba, Sr, Al, or a mixt. of the oxides or carbonates of Ca and Mg in which the Mg compd. must exceed 75% of the mixt. The briquets are produced by mixing ground natural or artificial Fe_2O_3 , as pure as possible, with ground natural or artificial carbonates or oxides of Mg, Sr, Ba,

etc., including $\text{Al}(\text{OH})_3$, stirring the mixt. with H_2O to form a paste, pressing in molds, drying, and firing before use. Cf. C. A. 9, 1376.

Hydrogen. BADISCHER. Brit., 16,494, July 10, 1914. In the production of H by the process described in 27,955, 1912 (C. A. 8, 1853), there is employed, as catalyst, spathic Fe ore, or a hydroxide Fe ore, which has not at any stage of the process been subjected to a temp. appreciably higher than 650° ; the catalyst may be employed in the form of grains, or may be made into shaped pieces with the aid of binding agents, such as hydroxides or salts of Fe, Al, etc.; the presence of P, S, or Si is preferably avoided.

Hydrogen. K. SCHAEFER. Brit., 16,140, July 6, 1914. In the production of H by the alternate oxidation of Fe by means of steam and reduction of the oxide by reducing gases, the central zone of the vertical reaction chambers is filled with coarser particles of Fe than the outer portions to ensure ready passage of gas through the central zone. Vertical Fe bars or tubes may be disposed in the central zone with the charge loosely packed around them. A loose layer of broken pieces of stone or the like may be disposed in proximity to the charge at either end and serve as a heat accumulator or to superheat the steam or for burning the waste gases with air.

Fire-proofing. T. J. I. CRAIG and WHIPP BROS. & TOD. Brit., 16,153, July 7, 1914. Fabrics or fibers are fire-proofed by treatment with a soln. of alkali aluminate and then with a soln. of alkali hydrogen carbonate. After the treatment with alkali aluminate, the fabric may be dried and subjected to the action of CO_2 gas at a temp. above 100° before the treatment with the alkali hydrogen carbonate soln. The acid alkali carbonate soln., or the CO_2 gas, or both, may be applied under pressure. The result of the process is to ppt. an insol. double carbonate of alkali and Al.

Artificial mother-of-pearl. E. DOUZAL, L. DAVIAN and E. DELOUME. Brit., 16,070, July 6, 1914. Pellicles or layers of muscovite and gelatin or the like are superposed alternately and compressed while heated, and the block thus formed is immersed for a short time in a bath of HCHO . The muscovite may be previously immersed in a soln. of TiCl_4 and then strongly heated. The layers of gelatin or the like may be coated with fish scales or scales of pholerite or nacrite. The muscovite layers may be coated with the gelatin by immersing them in a soln. of that substance with or without fish scales or pholerite in suspension.

Treating waste liquids. G. EBRILL. Brit., 15,799, July 1, 1914. Nitrogenous substances are recovered from waste liquids by adding a precipitant, *e. g.*, passing the mixt. through a centrifugal filter, and then into a settling-tank in which the scum rises to the surface and is removed. The recovery of casein from creamery waste is specified.

Printing surfaces. S. A. C. KRISTENSEN. Brit., 15,935, July 3, 1914. Printing plates of light wt. suitable for ready transportation are made from a compd. sheet material as follows: The fibrous sheet of unsized paper, linen, etc., coated with metal compn., preferably Al powder and water-glass, as described in the parent specification, is backed with a carrier comprizing a thin sheet of substance capable of retaining impressions. A thin sheet of celluloid is suitable. This compd. sheet is molded on a matrix of the original plate. The matrix may be a cast in type metal from a flong made preferably by pressing a sheet of the compd. material described above into a matrix composed of Pb faced with a very fusible metal taken from the original. Cf. C. A. 9, 1672.

Electric insulating composition. F. D. BULL, W. HERMANN and RADONIT SYNDICATE. Brit., 26,716, Nov. 20, 1913. A fire and oil resisting and electrical insulating compn. is made from dried and ground skins, sinews, hoofs, etc. The animal matter is dried at about 80° and ground, and to it is added about 10% of fine wood pulp, and 10% of asbestos. To this is added 1% of asphalt, pitch, etc., and 20% of a liquid

made up of equal parts of H_2O , animal or vegetable oil or fat, and fresh blood, and the whole is thoroughly mixed. If a hard compn. is required, the quantity of oil is reduced. The compn. is pressed in molds at a pressure of about 100 atms. and a temp. of 75° . The compn. after drying may be cut to shape; or the molds may be suitably shaped.

Horn or ebonite substitute. E. KRAUSE and H. BLÜCHER. Brit., 76, Jan. 1, 1914. Yeast residues, such as those obtained in the manuf. of yeast exts., are hardened with $HCHO$ and the product is molded and pressed with heating. Albuminous substances and suitable filling materials and suitable oils such as castor, linseed, or paraffin oil may be added to the compn. In an example, 100 parts of a paste of the yeast residue are mixed with 15 parts of 40% $HCHO$. H_2O is removed as far as possible by pressing and evapg., and the mixt. is molded and pressed at 100° at a pressure of several hundred atms. In another example, 30 parts of dry powdered albumin are added to 100 parts of yeast residue and 20 parts of $HCHO$.

Metal adsorptions. ELEKTRO-OSMOSE AKT.-GES. (GRAF SCHWERIN GES.). Brit., 15,267, June 25, 1914. Metals are reduced to dust in the presence of suspension colloids; scattering the metal, *e. g.*, Ni, by means of an elec. arc in the presence of a colloidal suspension of say silicic acid, is the preferred method. Suitable colloids are carborundum, clay, finely divided C, kaolin, or amorphous silicic acid. The metal adsorptions, particularly Ni adsorbed by silicic acid, are suitable as catalysts, *e. g.*, in hardening fats.

Separating air into oxygen and nitrogen. H. RUNGE. Brit., 3,420, Feb. 10, 1914. The sepn. is effected by means of liquefaction and rectification. The air is subjected preliminarily to a process of dialysis to increase the % of O therein. This is preferably effected by providing a taffeta sack in the suction inlet of the compressor.

Sulfuric acid. E. HARTMANN (v. E. HARTMANN & F. BENKER). Ger., 284,636, Dec. 13, 1912. A tower system comprizes 6 or more towers. The first tower forms with the next to the last tower in the series, and the second tower forms with the last tower in the series, each a completely closed acid spraying system. The method of spraying towers 3 and 4 remains unchanged. In the usual method of operation, the acid is carried through the series of towers by the gases in the form of a mist, entering tower 5, which performs, in the main, the function of the Gas-Lussac tower, the performance of which is influenced so that an increased consumption of HNO_3 results. To overcome this difficulty the towers 1 and 5, and 2 and 6 are paired, so that the acid from tower 5, which has the highest HNO_3 content, is conducted to tower 1, so that the formation of H_2SO_4 is effected in the first of the series of towers. As a result of this method of spraying, HNO_3 content of the acid flowing from tower 1 is dependent upon the temp. of the entering gases. If this is not sufficient, the acid can be drawn from tower 2. This is possible inasmuch as tower 2 obtains the acid from tower 6 which contains less nitrous gases than does tower 5.

Sulfuric acid. METALLBANK UND METALLURGISCHE GES. AKT.-GES. and H. KLENCKE. Ger., 284,995, Nov. 25, 1913. Increasing the capacity of a tower system without chambers for the manuf. of H_2SO_4 , by directing the gases, from above downwards, in part or all of the acid-forming towers. This practice has been followed already in the operation of denitrification towers (Glover towers). However, the operation of such a tower is fundamentally different from that of an exclusively acid-forming

tower. When the gases are downwardly directed in acid-forming towers they come in contact with the strongest nitrous gases present in the particular tower at a point where the gases have a greater content of SO_2 . As a result, nitrous and roast gases pass in intimate contact the entire height of the tower filling, so that a very vigorous reaction can take place. At the same time the resulting acid vapors may condense more readily without opposing an increased resistance to the gases, whereby the capacity of the tower is increased. The gases pass from one tower to the next in a condition much better suited for further reaction.

Nitrogen oxides. BADISCHE. Ger., 284,815, Mar. 13, 1914. See Brit., 13,687 (C. A. 9, 3337).

Alumina. F. HIRSCH and F. RUSS. Ger., 284,601, Apr. 10, 1912. Obtaining alumina from aluminate lyes by the Bayer process, according to which the aluminate lyes, obtained from bauxite, are stirred up with $\text{Al}(\text{OH})_3$. Expts. have shown that by the passage of ozonized air or ozonized O through such aluminate lyes, before or during the stirring process, the lyes which are otherwise yellow, yellowish red, to deep brown, are completely decolorized, so that the process may be carried out more quickly, the decompn. resulting from the agitation is more complete, and the resulting $\text{Al}(\text{OH})_3$ and the compds. obtained therefrom (e. g., $\text{Al}_2(\text{SO}_4)_3$) show a pure white color. The yield is greater, power is saved, and the app. for a certain amt. of product can be much smaller. While a lye treated according to the usual process gave a yield of only 31.4% pptd. $\text{Al}(\text{OH})_3$, the ozonized lye gave a yield of 60.4% $\text{Al}(\text{OH})_3$.

Pure colorless ammonium salts. GEBR. HINSELMANN. Ger., 284,641, Sept. 23, 1913. Salts which do not discolor upon storing are obtained from slightly colored crude salts, by heating the crude salts without volatilization in order to convert the troublesome H_2O -sol. impurities into insol. substances, and to free the salts therefrom by crystn. The impurities are converted, by a definite heat treatment of the salt, into H_2O -insol. compds., with marked intensification of color, so that they may be readily sepd. by filtration, and so that with a single crystallization of the filtered soln. a salt seps. which is pure white and not subject further to discoloration. E. g., NH_4SCN , which is present in NH_4NO_3 , not discernible in the fresh salt but imparting to the salt upon long standing a yellow or red color, cannot be removed from the salt even by repeated filtration and recrystallization. If, however, the solid crude NH_4NO_3 be heated to 135–140°, the NH_4NO_3 reacts with the NH_4SCN in such manner that the latter is converted into an insol. compd., apparently perthiocyanogen, which, upon subsequent soln. of the crude salt and filtration, can be obtained in the state of a fine slime from the liquor. The filtrate then yields a white or slightly yellow odorless NH_4NO_3 , which does not change even upon long keeping. In like manner, from the condensate may be obtained a stable white NH_4Cl , as practiced in the direct recovery of NH_3 from distillation gases. E. g., in the direct recovery of NH_3 salt from distillation gases, the gases are cooled to about 90°, and a condensate seps. which contains, principally, NH_4Cl , is exceptionally colorless, but contaminated with thiocyanate and S compds., as well as H_2O -sol., tarry substances. If the salt obtained from this condensate be heated to 200–250°, the salt blackens as a result of sepn. of C and the conversion of the impurities into H_2O -compds. After soln. of the salt and pptn. of the H_2SO_4 by means of BaCl_2 , filtration, and crystallization, a white odorless pure salt is obtained, and a black powder is left which can be used as a pigment.

Compounds of the rare earth metals. GEBR. SIEMENS & Co. Ger., 284,889, Apr. 2, 1913. Fluorides and phosphates of the rare earth metals are obtained by adding the corresponding compds. of the alk. earths or of Mg or Al to a soln. of the rare earths. An aq. chloride soln. or other aq. salt soln. can be employed for the soln. of the rare earth. The fluorides or phosphates of the alk. earths are suitable as pre-

precipitants. The compds. of the rare earths are obtained directly in the form of a rapidly settling uniform ppt. suitable for further working. E. g., the waste liquors of the Th manuf. can be pptd. by means of finely ground natural fluor spar, which produces a ppt. of the fluorides of the rare earths. Also, native ground apatite or other natural Ca phosphate may be employed, giving then the phosphates of the rare earths. When fluor spar is employed, some HCl or other mineral acid should be used to hasten the reaction, and the mass should be heated and stirred. E. g., rare earths 15.7 kg. (consisting of Ce chloride $\frac{1}{3}$ and La and Di chlorides $\frac{1}{2}$) are dissolved in H₂O 84.3 liters and heated to boiling, whereupon HF 7.5 kg. and HCl 1-2 kg. are added to the soln. with stirring. The soln. is maintained at the b. p. until the earths have been completely pptd., a period of 1-2 hrs. being sufficient. An addition of NaCl hastens the sepn. The ppt. is washed with H₂O, filtered, and dried. The yield of dry powder is 12.1 kg. fluoride, i. e., 96% of the theoretical.

Thionylchloride and sulfur tetrachloride. CHEM. FABRIK BUCKAU. Ger., 284,935, Apr. 15, 1914. COCl₂ and SO₂ are allowed to interact at temps. of 200° and above. These are preferably conducted, in gaseous state, over heated catalyzers. CO may be mixed with these gases, or a mixt. of CO and Cl may be used instead of COCl₂. The mixt. of SO₂ and Cl may be replaced by SO₂Cl₂ which is heated, in vapor form, with CO. E. g., liquid SO₂ 10 kg. is mixed with COCl₂ 10 kg., and the mixt. is heated in a high pressure autoclave for several hrs. at 250°. The CO₂ forming as a result of the reaction may be allowed to escape, from time to time, to relieve the pressure. After the reaction has proceeded to completion, the residual CO₂ and the excess SO₂ are allowed to escape, and the reaction product is subjected to distn. after the addition of some free S to convert the higher S chlorides into S₂Cl₂ which, by reason of its high b. p., can be sepd. readily from SOCl₂. If a mixt. of 2 vols. SO₂, 1 vol. COCl₂, and 3 vols. CO is conducted through a porcelain tube filled with charcoal heated to 400°, the escaping gas condenses, in part, in suitable condensers, while CO escapes. The condensate consists essentially of S₂Cl₂, mixed with small amts. of SOCl₂ which can be removed by distn. The manuf. of SOCl₂ is materially cheapened by this process.

Hydrogen. CHEM. FABRIK GRIESHEIM-ELEKTRON. Ger., 284,816, Mar. 14, 1914. The H is manufd. from C, gases containing CO, steam and alkali or alk.-earth hydrides. When gases containing CO and steam are conducted over Ca(OH)₂ or NaOH at temps. of 450-550°, H is obtained. This reaction is favored materially by employing increased pressure and correspondingly increased temps. In the same period of time 4 times as much H can be secured as when operating at atm. pressure. Either steam or a mixt. of steam and gases containing CO is conducted over a mixt. of alkali or alk.-earth and C, or a mixt. of steam and CO is conducted, at an increased pressure, over alkalies or alk.-earths. Pressures of 10-100 atm. and over are employed. If gases containing CO are to be acted upon alone, good yields are secured at 5 atm. pressure. With the use of lime, a temp. of 600-800° is suitable, and with the use of Ba(OH)₂ and alkali, a materially lower temp. may be employed. Especial advantages are secured by conducting steam, under a pressure of 10 atm. and more, over a mixt. of lime and coal, almost pure H being obtained. The reactions proceed in the sense of the equations: $C + 2H_2O = CO_2 + 2H_2$; $CO_2 + CaO = CaCO_3$; $CO + H_2O = CO_2 + H_2$. Since the thermal effect is strongly positive, generally the application of heat is not required in sufficiently large app. If the process is carried out without the use of water-gas, the generator is filled with a mixt. of coal and lime, and the combustion of the lime and the production of H₂O can be effected in a tower. The coal present in the tower with the lime serves both as a source of heat and for the decomposition of the steam. When the charge has been brought to the desired temp., the supply of air is discontinued, and H₂O or steam is conducted, from above, over the

mixt., at 20 atm. pressure. The burned lime is discharged from below, mixed with fresh coal, and returned to the process. Brown coal or charcoal is preferred since they react more quickly and at lower temps. than hard coal and coke.

Solid plastic masses. C. HAGENBORG. Ger., 284,214, Feb. 19, 1914. Addition to 274,179 (C. A. 8, 3129). Instead of the more or less turbid product obtained by the principal process, a clear opalescent or transparent mass is obtained if the albumin soln. or the blood serum is brought almost or quite to dryness by heating with HCHO soln. and alkali peroxide or with a neutral peroxide, such as H_2O_2 , in the presence of a caustic alkali. E. g., 10 parts of a 40% HCHO soln. and 0.25 part Na_2O_2 are added, with stirring, to 100 parts of ox blood serum, and the mixt. is evapd. to about $\frac{1}{4}$ its vol. The residue mixes with the phenol and HCHO mixt. clear or almost clear, and does not become turbid upon subsequent heating. Even better is the evapn. of the serum mixt. to a gelatinous consistence or wholly to dryness. The residue is then heated with a mixt. of 100 parts phenol and 100 parts HCHO soln. (40%) or 40 parts trioxymethylene, and 20 parts Na_2SO_3 , for 8-10 hrs., at 80-90°.

Mixture of asbestos fiber and hydraulic binder. J. FÜRST ZU COLLOREDO-MANNSELD. Ger., 284,595, Apr. 2, 1913. Construction and operation of an app. for mfg. the mixed product.

Mixing drum for preparing a mixture of asbestos fiber and hydraulic binder. J. FÜRST ZU COLLOREDO-MANNSELD. Ger., 284,599, Apr. 2, 1913.

Reflectors. M. WISKOTT. Ger., 284,611, Dec. 10, 1913. Plastic masses, such as cement, gypsum, casein, hard gum, papier maché, clay, and the like, are shaped over forms with parabolic, hyperbolic, and the like surfaces. The shaped products are not treated further by polishing.

Separating substances of different specific gravities. A. GRÜNDLER. Ger., 284,666, Oct. 30, 1912. The process is applicable especially to firing residues. A sepg. liquid of intermediate d. is employed. Cf. Fr., 460,225 (C. A. 8, 2798).

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLININGER.

The influence of alumina on the fusibility of glasses. FELIX SINGER. *Keram. Rundschau* 23, 65-6, 78-9, 95-6, 103-4(1915).—Modifications of the ordinary window glass are made by additions of Al_2O_3 , by use of pegmatite. Variations are also made in Na_2O , CaO and SiO_2 . The results show that small amts. of Al_2O_3 increase fusibility. The improvement by use of Al_2O_3 is especially noted with 0.6 CaO , 0.4 Na_2O and 2.5-3.0 SiO_2 .
R. K. HURSH.

Studies of glass fusions with antimony compounds. L. SPRINGER. *Sprechsaal* 48, 211-12, 221-22(1915); cf. C. A. 9, 2135.—In both leadless and lead glasses Sb_2O_3 and $Pb_2(SbO_4)_2$ had no coloring effect; metallic Sb was incompletely dissolved; Sb_2S_3 gave yellow but caused turbidity in Pb glass.
R. K. HURSH.

Turquoise-blue copper glazes. H. HECHT. *Sprechsaal* 48, 201(1915).—Silicates of K and Na with $3SiO_2$ dissolve CuO with deep blue color. Introduction of CaO , MgO , BaO , B_2O_3 , or Al_2O_3 gives green. With $3SiO_2$ equimol. parts of K_2O and PbO give blue; increase of PbO gives green; B_2O_3 and Al_2O_3 give intense green. Cf Hecht, *Tonind. Ztg.* 1895, 453, and Granger, C. A. 8, 1000.
R. K. HURSH.

Thermal conductivity of refractory materials. ANON. *Brit. Clayworker* 24, 128(1915).—Review with comments.
C. H. KERR.

Deterioration of fire clay. T. HOLGATE. *Brit. Clayworker* 24, 122(1915); see *C. A.* 9, 2384. C. H. KERR.

The replacement of English kaolin (China clay) by domestic materials. R. RIECK. *Specksaal* 48, 183-5, 191-3, 199-201(1915).—Tests show German kaolins generally finer grained than china clays. Hygroscopicity was detd. by desiccation over 10% H_2SO_4 and by drying at 120°. R. concludes that the Atterberg plasticity factor is less a measure of plasticity than hygroscopicity. The best white is obtained with lowest $TiO_2 + Fe_2O_3$. To replace English clay use one of moderate plasticity, low Fe_2O_3 and very low TiO_2 . R. K. HURSH.

Gas versus electrically heated ovens. G. H. TROUT. *Iron Trade Rev.* 57, 526 (1915).—A discussion of the advantages of clean producer gas over elec. heat for firing enamelling ovens. The cost with producer gas is claimed to be less than one-third of the cost of elec. heating. F. A. S.

French cones and Seger cones. A. GRANGER. *Céramique* 18, 22-3(1915).—The compn. of the French and of Seger cones is described. J. C. EVANS.

Properties of soil particles and the plasticity of soils (ATTERBERG) 15. Electrical porcelain (AUSTIN, *et al.*) 4.

Silica glass. P. L. PFANNENSCHMIDT. *Brit.*, 420, Jan. 7, 1914. The glass is manufd. in an elec. furnace fitted with several resistances which are specially adapted to be rapidly withdrawn. The interior of the furnace is filled with sand, and the current is passed through a number of resistances arranged in parallel and series, in graphite blocks. When the sand is fused, the resistances are drawn out on a trolley running on rails. One of the hinged lids is then opened, and the mass of fused SiO_2 is rapidly withdrawn. The distance apart of the walls of the furnace, and hence the thickness of the slab of SiO_2 produced, can be adjusted by screws. The furnace is mounted on trunnions so that it can be charged in the horizontal position and turned into the vertical position for heating operation.

Treating ceramic argillaceous materials. E. TUSCHHOFF. *Brit.*, 29,421, Dec. 20, 1913. These materials are prepared for molding by grinding the material sufficiently fine to pass through a bolting screen of 5,000 meshes per sq. cm., then submitting the ground material, mixed with a small amt. of H_2O , oil, or other liquid assisting compressibility, to a kneading treatment in a pug-mill or like machine by which the material is pressed into cakes or lumps, which, when crumbled up and if necessary screened, yield a grain suitable for the molding process.

Glass-blowing machine. FAIRMOUNT GLASS WORKS. *Ger.*, 284,546, Apr. 30, 1913. Machine for blowing hollow glassware. Cf. *C. A.* 9, 137.

Glass-blowing machine. H. KÖHLER. *Ger.*, 284,547, May 28, 1913.

Glass-blowing machine. GLASMASCHINENFABRIK SYSTEM J. WOLF. *Ger.*, 284,649, May 9, 1914.

Basic lining for revolvable tube furnaces. W. HAPPE. *Ger.*, 284,809, Jan. 4, 1914. Addition to 281,207 (*C. A.* 9, 2301). For the burning of the lining, the sheet Fe shell is replaced by a structure of refractory material which may be finally removed by breaking up into small pieces, while the furnace is hot. If stones or plates of MgO , chromite, clay, or C are used, they may be left in the furnace, and serve, for the first run, as the lining. The sheet Fe segments are only necessary when stamping in the plastic mass. The warm mass is stamped behind the sheet Fe shell, and allowed to

cool. The cooled mass has sufficient strength to allow removal of the sheet Fe shell from the cold furnace. In place of the shell, a ring of arch brick is built in the lining mass. When the refractory masonry work is finished, the fire is kindled to coke the gas and solidify the basic lining, or hot gas is conducted through the interior. After cooling is complete, the refractory work is removed, which may be accomplished readily without injury to the lining. The removed material can be used again.

Refractory coarsely porous masses. L. KERN. Ger., 284,435, Dec. 4, 1913. Construction and operation of a furnace for their manuf. A mixt. of silicates, alumina, and the like, mixed with combustible matter, is burned, with the employment of a strong draught.

Tunnel furnace. P. J. LENGERSDORFF. Ger., 284,810, Feb. 15, 1914. The furnace is built up of portable chambers.

Tunnel furnace for burning bricks and pottery. W. DRAYTON. Ger., 284,338, Sept. 30, 1913. The cars in this furnace are adapted to run lengthwise.

Charging and mixing apparatus for clays. N. ORT. Ger., 284,753, Sept. 18, 1912.

20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

The German cement industry and the war. ANON. *Chem. Ztg.* 39, 769(1915).

Standard specification for cement. ANON. *Yearbook Am. Soc. Testing Materials*

1914, 290-317.—*Natural cements:* Residue on no. 100 sieve shall not be more than 10%, on no. 200 not more than 30%. It shall not develop initial set in less than 10 min., and hard set in less than 30 min. or in more than 3 hrs. The minimum tensile strength for briquets 1 sq. in. in cross-section shall be as follows, and the cement shall show no retrogression in strength within the periods specified: neat cement, 24 hrs. in moist air, 75 lbs.; 7 days (1 in moist air, 6 in H₂O), 150 lbs.; 28 days (1 in moist air, 27 in H₂O), 250 lbs.; 1:3 Ottawa sand mortar: 7 days (1 in moist air, 6 in H₂O), 50 lbs.; 28 days (1 in moist air, 27 in H₂O), 250 lbs. Pats kept in moist air for 24 hrs., then in air at normal temp., and pats kept in moist air for 24 hrs. and then in H₂O as near 70° F. as practicable shall remain firm and hard and show no disintegration, distortion, checking or cracking for at least 28 days. *Portland cement:* Sp. gr. shall not be less than 3.10. When sp. gr. is low cement sample may be ignited at low red heat and sp. gr. redetd. Loss in wt. shall not exceed 4%. Residue on no. 100 sieve shall be not more than 8% and on no. 200 sieve not more than 25%. It shall not develop initial set in less than 30 min. and must develop hard set in not less than 1 hr., nor more than 10 hrs. Minimum tensile strength requirements on briquets with 1 sq. in. cross-section (neat cement): 24 hrs. in moist air, 175 lbs.; 7 days (1 in moist air, 6 in H₂O), 500 lbs.; 28 days (1 in moist air, 27 in H₂O), 600 lbs.; 1:3 Ottawa sand mortar: 7 days (1 in moist air, 6 in H₂O), 200 lbs.; 28 days (1 in moist air, 27 in H₂O), 275 lbs. Cement shall show no retrogression in strength within the period specified. Pats for constancy of vol. shall be kept in moist air for 24 hrs. (a) A pat is then kept in air at normal temp. for at least 28 days. (b) Another pat is immersed in H₂O as near 70° F. as practicable for at least 28 days. (c) A third pat is exposed in any convenient way in an atm. of steam above boiling H₂O for 5 hrs. The pats shall remain firm and hard and show no signs of distortion, checking, cracking or disintegrating. Cement shall not contain more than 1.75% SO₃, and not more than 4% MgO.

A. A. KLEIN.

New Argentine specifications for portland cement. *Mill. Z. Deut. Port. Cement* 3, 333-6, 347-50(1914).—The hydraulic modulus must be at least 1.7; ignition

at a red heat for 30 min. must give a sp. gr. of at least 3.05 in the LeChatelier-Candlot volumometer. Not over 5% residue may remain on the 900-mesh nor over 30% on the 4900-mesh sieve. Normal consistence is detd. with the Tetmeyer piston and setting time with the Vicat needle. Initial set is 35 min. to 3 hrs. and final set not over 10 hrs. Tension tests with the shot running at the rate of 100 g. per sec. must show at least 30 kg. sq. cm. at 7 days and 35 kg. sq. cm. at 28 days. The mortars are machine-mixed, are hammered into the molds and must show in tension 12 kg. sq. cm. at 7 days and 16 kg. sq. cm. at 28 days. Vol. constancy is estd. with cold H₂O pats and LeChatelier tongs, not over 10 mm. expansion being allowed after heating at 100° for 6 hrs. One evapn. is made for SiO₂, Fe is pptd. with KOH, dissolved and reprecipitated with NH₄OH and CaO is weighed as sulfate. SO₃ detns. must stand for 24 hrs. For general work 1.2% SO₃ is permitted, while for work in fresh H₂O or in air up to 2% SO₃ is allowed. The MgO may not exceed 4%. Cf. C. A. 7, 1792; Burchartz, C. A. 7, 3651.

A. J. PHILLIPS.

Tests to determine shrinkage and time effects in reinforced concrete. F. R. McMILLAN. Univ. of Minnesota. *Eng. Contr.* 44, 306-10(1915); cf. C. A. 9, 1985, 3345.—Beams tested were 5½ in. deep, 30 in. wide and 12 ft. long between supports. Concrete consisted of 100 lbs. cement, 2 cu. ft. sand, 4 cu. ft. stone, hand mixed. Results show that shrinkage of ¾ to 1 in. in 100 ft. can be predicted when concrete is exposed to ordinary dry air of a heated building. Changes in moisture content will retard shrinkage and even cause swelling. The yielding of concrete under compressive stress with time is greater as the unit stress is greater and goes on indefinitely. The deformation was found to be 3-5 times that produced immediately upon application of load. The time yielding under stress combined with shortening due to shrinkage may result in deformations 15-20 times those expected from calcns. A. A. KLEIN.

Results of the testing of cement, sand and the concrete produced from their mixture. H. BURCHARTZ. *Mitt. kgl. Materialprüfungsamt* 32, 474-96(1914); *Chem. Zentr.* 1915, I, 811.—Tests were made of the sand, cement and the concrete to det. the qualities of the concrete, the strengths of various mixts., to establish the influence of the age on the hardening process and the relation between the properties of the mixts. and the strength of the concrete. Curves showing the tensile, compressive and bending strengths are given. Especially fine grinding does not necessarily give the highest strengths.

J. C. EVANS.

The setting and hardening of portland cement. H. SCHEIDLER. *Mitt. Deut. Port. Cement Ind.* 4, 13-4, 20-2, 25-8, 32-3(1915).—In the microscopic examn. of fine powders on slides with H₂O, for their hydration behavior, alizarin orange and cryst. alizarin in ammoniacal soln. were found suitable for CaO and chromotrop 2R and cyanin for Al₂O₃. Varied mixes of the silicates and aluminates were burned in Pt crucibles up to 1480° and examd. microscopically for their behavior in hydration. With 1.5 CaO.Al₂O₃ and CaO.SiO₂ no action was noted, but as the CaO in the silicate was increased the amount of gel formed likewise increased. In the mixt. 2CaO.Al₂O₃ with CaO.SiO₂ clusters of radiating needles were found which were not found in hydrated clinker. The plate crystals increased in size and number as did the amt. of gel with increase in the CaO content of the mixts. The combination 3CaO.Al₂O₃ with 2CaO.SiO₂ produced typical Ca silicate needles which were observed with a dark field illuminator. The latter pass over to a fine-grained gel. For comparison with Keiser-mann's formula for port. cement 3CaO.Al₂O₃ + 4(2CaO.SiO₂) (cf. C. A. 5, 1328), one mol. each of analcite, laumontite, chabasite, leucite and a synthetic zeolite CaAl₃-Si₂O₇ were mixed with 10 mols. of freshly burned CaO and observed on slides after mixing with water. The synthetic zeolite showed the least reaction but all gave gel and silicate needles after 5 days while no Ca(OH)₂ crystals were observed at all. From

sintering these same mixts. and a study of their structural formulas, it is concluded that the zeolite radical in cement raw mixes is broken down by the CaO to form $3\text{CaO} \cdot \text{Al}_2\text{O}_3 + 4(2\text{CaO} \cdot \text{SiO}_2)$ and by varying the CaO till a well sintered clinker was formed which would hydrate with H_2O , the boundary limit for good clinker was placed at 56.71 CaO, 12.91 Al_2O_3 and 30.38 SiO_2 . Comparative hydration tests of underburned, normal and overburned cements showed that the normal cements gave the most regularly developed crystals in the shortest time. The overburned material was slower in reacting while the underburned cement reacted very weakly even after a long time. From a comparison of the compressive strengths of 86 cements with their hydration behavior under the microscope it is stated that the value of the cement may be predicted from the amt. of plate, needle and gel formation taking place. The rate of cooling of the clinker influences the formation of silicate needles during hydration, since if the clinker is very rapidly cooled, the viscous silicate remains in a metastable condition and on mixing with water the gel formation takes place with the exclusion of other products. Further, $3\text{CaO} \cdot \text{SiO}_2$ sintered without the presence of Al_2O_3 dusted down and gave silicate needles on hydration, while with a burn in which Al_2O_3 was present only gel formation was noted on hydration. Ca aluminate hydrated as a gel and it is probable that the silicate needles and gel vary only in their H_2O content. All hydration products are referred to as plates, needles or gel and no optical data are given.

A. J. PHILLIPS.

The effect of soft soap on cement mortars and concrete. ANON. *Mitt. Dent. Port. Cement Ind.* 4, I, 7-9(1915).—A review with bibliography. The fatty acid of the soap not only combines with the CaO to make an impermeable mortar, but also by removal of CaO prevents the formation and growth of crystals of $\text{Ca}(\text{OH})_2$ which might cause disintegration.

A. J. PHILLIPS.

Preservation of cement in presence of oils and fats. S. CANEVAZZI. *Mitt. Dent. Port. Cement Ind.* 3, 429-30(1914); cf. C. A. 6, 3507.—Tension and compression tests are given on briquets stored for 20 months under pure and rancid olive oil. The results show that when 20% of the sand is replaced by fine ground puzzolana, there is no deterioration in the strength of the cement and only a loose spongy coat of soap is formed on the surface of the briquets.

A. J. PHILLIPS.

Microscopic study of concrete. N. C. JOHNSON. *J. Am. Soc. Mech. Eng.* 37, 516-25(1915); cf. C. A. 9, 1380. Discussion. J. R. FREEMAN, et al. *Ibid* 525-8.—Further investigation is called for on the solubility of the ultimate compds. resulting from the setting of cement. Attention is likewise called to several cases in which concrete did not set even after several weeks until a shock was administered such as the running of machinery or the working of air riveters on concrete forms. Recent investigations have shown that CaO and MgO, likewise Al_2O_3 and Fe_2O_3 , do not act chemically alike in cements; therefore they cannot be used as chem. equivalents in computing formulas. Cf. Upton, C. A. 9, 2137.

A. J. PHILLIPS.

Relative resistance to wear of concrete made of different aggregates. C. F. SHoop. *Bull. Univ. Minn.; Eng. Contr.* 44, 144-7(1915).—Different aggregates were used in a 1-2-4 concrete from which rings were made to fit a Talbot-Jones brick rattler, standard cast iron shot being used. The speed was adjusted to give a tumbling as well as abrasive action. In addition the rings were subjected to the abrasive action of horse-shoe calks. Comparative tests were made and tabulated for crushing flexure and shear. The results showed that concrete cured wet and kept wet showed minimum abrasion, as the shot were covered with a paste which acted as a cushion. With gravel concrete the gravel was kicked out forming pockets which wore to holes; with hard stones the cement bond wore away leaving an uneven surface and, further, cleavage lines in the stone were disadvantageous. Crushed stone gave a better bond than gravel and the

most evenly wearing surface was found with sandstone, as the bond and stone wore down together. In rattling with calks the % of wear was not found to be a direct measure of the value of the stone for concrete roads.

A. J. PHILLIPS.

The nature of high magnesia portland cements. P. H. BATES. *Mitt. Deut. Port. Cement Ind.* 4, 31-2, 43-5, 51-2(1915); cf. *C. A.* 8, 1653; 9, 2702. Discussion. R. DYCKERHOFF, C. GOSLICH AND M. GLASENAPP. *Ibid* 58-62.—Unsintered cements containing high MgO content show no harmful expansion while if the concrete is sintered expansion starts at the earliest in 1 yr. and the test interval noted by Bates is too short for conclusive results. The glassy material in clinker forms 20-25% of the whole and contains MgO, Fe and alkalis. With constant burning temp. the more MgO there is in the clinker the less fusible is the glass and the less well sintered is the clinker. In rich MgO mixts. a part of the MgO goes into the silicates and aluminates (cf. Klein and Phillips, *C. A.* 6, 3172) displacing some CaO so that free CaO remains in the clinker. Fe oxide in the presence of MgO goes into the glass with difficulty and tends to remain free (cf. Glasenapp, *C. A.* 8, 2236). From the strength test figures it is concluded that not over 7.4% MgO content in B.'s burns will give cements passing specifications. B.'s burns were more fusible than the usual cement raw mixes on account of the addition of feldspar which increased the amt. of alkali present. MgO also has a tendency to prevent the taking up of Fe by the clinker materials. The presence of spinel and montecellite in B.'s burns is considered as an indication that satn. of the clinker minerals by the bases present was not complete on account of insufficient temp. being used in burning.

A. J. PHILLIPS.

The use of coal tar in creosote. Report of Committee on Wood Preservation. *Proc. Am. Roy. Eng. Assoc.* 16, 825-7(1915).—Recognizing that the use of creosote-coal-tar mixts. for the preservation of timber is extensive, but not possessing sufficient data specifically to recommend their use, the committee proposes a specification covering refined coal-tar creosote solns. and recommends its use to those who desire to purchase such an oil. The purchaser should be permitted to exam. the coal tar before it is mixed with the creosote, as a detn. of the quality of the tar after its addition is difficult. Precautions are given for the use of those desiring to purchase crude coal tar and creosote and mix them at the treating plant. The crude tar should not contain over 5% free C, and not over 25% should be used. The mixt. should be made at 82.3°.

GEO. M. HUNT.

Water in creosote. Report of Committee on Wood Preservation. *Proc. Am. Roy. Eng. Assoc.* 16, 827-32(1915).—Water may become mixed with creosote (1) in the process of manuf., due to presence of water in the crude tar, condensation from steam or air used to agitate the tar in the stills, leaky condenser coils, steam pipes inside of oil lines or steam coils in storage tanks; (2) in transit, due to leaky steam coils in tank cars or leaky seams or bulkheads in ships; (3) at the treating plant due to the treatment of wet timber or steamed timber, leaky steam coils, and the use of a water seal in uncovered storage tanks. The detn. of water content is simple but great care must be used in sampling. Methods of sampling are discussed. The amt. of water in creosote may be reduced by (1) siphoning after settling, (2) boiling and condensing the distillate to save any oil passing over, (3) by centrifuging. The use of water-free oil is desirable but not always practicable. In good practice, up to 3% of water is permissible. Allowance should be made when over 3% is present, but oils containing over 6% should never be used.

GEO. M. HUNT.

Rapid drying and preservation of wood by Nodon's electric process. C. DANTIN. *Genie civil* 65, 98-101; *Bull. Agr. Intelligence* 5, 1650-2.—The process consists of stacking timber 3-5 ft. high and inserting an electrode mat between each layer. These are made of pliable galvanized wire netting covered with strong jute cloths, satd. with

water and connected so that the a. c. passes through the thickness of each layer of timber. The treatment lasts 1-2 days, and the wood is then air-dried for a few weeks. The cell sap is completely oxidized so that only resinous substances remain. The cellulose is so modified that it does not readily putrefy and inherent fungi and germs are destroyed. One cu. m. (35 cu. ft.) of wood requires 150 amp.-hrs. with an e. m. f. of 40 v. for wood in full sap and 80-100 v. in unbarked wood kept for some time. Wood of all kinds can be thus treated and when used for road paving is more durable than untreated wood.

Strength tests of structural timbers treated by commercial wood preserving processes. H. S. BERRY AND J. A. NEWLIN. Forest Products Lab., U. S. Dept. Agr., *Bull.* 286(1915).—Strength tests were made of 8 × 16 in. bridge stringers of longleaf pine, loblolly pine and Douglas fir, untreated and treated by com. creosoting processes. The pine was steamed 4 to 6 hrs. at about 30 lbs. pressure before injecting the creosote. Part of the D. fir was treated by the "boiling" process and part by the "steaming" process. In the former the wood was heated in creosote 21½ hrs. at 215° F. (atm. pressure) and in the latter it was steamed at 90 lbs. for 4¼ hrs., followed by a 20-inch vacuum for 18½ hrs. before the creosote was injected. It was found that the treatments given caused practically no loss in breaking strength in the longleaf pine. The breaking strength of the loblolly pine was decreased, probably not more than 17%. The av. breaking strength of the D. fir, boiling process, was reduced 33 to 39%, steaming process 35%. Small clear sticks cut from the beams after breaking also showed loss in breaking strength due to treatment. Other tests indicated that weakening in D. fir may be due to stresses caused by rapid and unequal shrinkage in large beams. Further tests are being made. The authors make the following deductions: (1) Timber may be very materially weakened by preservative processes. (2) Creosote in itself does not appear to weaken timber. (3) A preservative process which will seriously injure one timber may have little or no effect on the strength of another. (4) A comparison of the effect of a preservative process on the strength of different species should not be made unless it is the common or best adapted process for all the species compared.

The protection of wood against decay by means of paints and coatings. F. MOLL. *Kunststoffe* 5, 169-71, 182-5, 210-2, 219-22(1915).—A general review and discussion based on the patent literature. These are grouped as follows: (1) tar and bitumen materials, (2) rubber, (3) mixts. with linseed oil or varnish, (4) water glass mixts., (5) lacquers, (6) mixts. of tar with resin, etc., (7) mixts. of tar with CaO, cement, etc., (8) mixts. of tar with salts (Zn, Cu, etc.), (9) mixts. of petroleum with other materials (tars, etc.), (10) CaO, clay, cement, and gypsum. A chronological list of patents by countries is given. Bibliography.

F. W. SUMMERS.

Recent results obtained from the preservative treatment of telephone poles. F. L. RHODES AND R. F. HOSFORD. *Proc. Am. Inst. Elec. Eng.* 34, 2343-87(1915).—The preservatives consist of distillates of coal- or wood-tar; the efficiency increases with the % of antiseptic and H₂O-insol. constituents. Data are given for treatment under pressure, in open tank and by the brush method. All timber should be completely framed and dry before treatment. Proximate soil compn. and altitude exert some influence. Rates of decay, increase in life by treatment, effect of seasoning and characteristic damages caused by decay and by insects are discussed. In the brush method, the preservative, at 49°-65°, is applied to the butts of seasoned poles with a brush. A second coat is applied after the first has worked in. Only dead oil of coal tar was used in the open tank method. Butt ends are immersed in the hot preservative and kept there till bubbling ceases. Greater penetration results and poles show little decay. Analyses of the preservatives are given and show naphthalene to com-

pose 45-50% of the distillate. The conditions to which the top of the pole is exposed cause more rapid removal of the volatile constituents than occurs in the butt. Tables, figures and a bibliography are appended.

W. H. BOYNTON.

Resinates for preserving wood and textiles (VAN VLOTEN) 26.

Cements. A. DENNY and D. G. ANDERSON. Brit., 16,560, July 11, 1914. A cement consists of a mixt. of anhydrous gypsum and from 2 to 10% of cryst. FeSO_4 or the equiv. of anhydrous FeSO_4 or salt, containing FeSO_4 with or without 1-4% of slaked lime or portland cement, and filling materials such as sawdust, coke breeze, etc. A soln. of the sulfate may be sprayed upon the gypsum. The product may be used as a flooring for ships' decks.

Chemistry of coal. J. P. WIBAUT. *Chem. Weekblad* 12, 758-65(1915).—W. reviews the following topics: the unsatd. compds. in coal, self-combustion, ability to form cokes, extn. with solvents, destructive distn., distn. at low pressure, inflammability, binding of N and origin of coal.

J. T. FLOHIL.

Methods of utilizing lignite. S. M. DARLING. *J. Gas Lighting* 131, 456-7(1915).—The article is a very satisfactory abstract of a report by D. on lignite of Southern Saskatchewan. The output of lignite in Saskatchewan is falling off from the former average of 200,000 tons annually, as lignite is not able to hold its own against coals. A large number of samples tested averaged 26.13 H_2O , 28.11 volatile hydrocarbons, 38.16 fixed C, 6.86 ash and 0.74% S. Exposure in warm air causes disintegration and slacking, while the tendency towards spontaneous combustion makes shipping and storing impracticable. Its light gases escape unconsumed, and it has no coking quality whatever. Its low % of S ensures absence of H_2SO_4 in burning and of H_2S in gasification. After the difficulties of carbonization are solved, lignite is found to yield good results by destructive distn. Early efforts gave a gas of poor illuminating value, unless burned in a mantle, but very serviceable for fuel and power-purposes: 15.9 CO_2 , 3.5 illuminants, 0.2 O_2 , 19.5 CO, 16.1 CH_4 , 43.9 H_2 , 0.9% H_2O , 3.2 c. p., 440 B. t. u. per cu. ft.; the residue (in a fine state of division) defied quenching. To get a large yield of oil, the process would be so slow as to be unprofitable, unless a continuous, slow heating retort be devised. The finally successful carbonizing bench is a vertical chamber oven, like a horizontal by-products oven, charged and discharged continuously. The crushed lignite is distributed to the several retort sections, and is later discharged and screened into bins in an atm. of (exhaust) steam in which it will not burn. Each layer or column of lignite in a retort section is 6 in. thick and has heat driven into it by heating flues on either side. A section holds 4 tons; an oven carbonizes 24 to 36 tons of raw lignite per 24 hrs. The gradual application of heat in carbonizing results in a substantial increase in the yield of hydrocarbon by-products, at high speed by a mechanical process. Rapid evolution of gas takes place at 700°-900° F. and evolution ends at 1000° F. Products per ton of lignite in round figures are 10,000 cu. ft. gas, 15 gal. oil or tar (water-free), 65 gal. ammoniacal liquor, 955 lbs. C residue, obtainable in good commercial practice. The fact that there is more gas from a ton of lignite than is required to carbonize the next ton offers several possibilities for disposal of a surplus heat value. On distn. of the oil or tar, the fractions are

11.5% light oils, 13.5% carbofic oils (some $C_{10}H_2$) 34.1% paraffin, and 24.5 hard pitch. Fifteen lbs. of $(NH_4)_2SO_4$ per ton of lignite are easily recovered by crystg. from H_2SO_4 soln. The dust and smaller sizes of the screened carbonized lignite must be briquetted; the larger lumps constitute an ideal producer-gas fuel. for the amt. of gas is equal to that from anthracite, while it is richer, has less tar and clinker, and burns more freely.

B. W. GRIMES.

The history of the development of water gas. O. B. EVANS. *Trans. Intern. Gas Congress 1915* (adv. copy), 35 pp.—The author gives a bibliography of the history of water gas mfr. He confines his paper to the description of the more important types of app. used in the past, pointing out the basic principles, advantages, and failures of each, and showing how the present app. has been evolved. The retort system was abandoned because of excessive fuel consumption and gas losses and inward leakages. This system was replaced by the generator retort system, in which the coke was heated by internal combustion, and the up and down run features introduced. The changes in app. necessitated by substituting bituminous for anthracite coal are described, such as coking the soft coal by waste heat or by the admixture of small quantities of secondary air. Principles of water gas operation are discussed: 1. The temp. of the carbureter and superheater is kept constant to 20°C . by large quantity of checker work and short blows and runs, and the gas oil is run in under only 20 lbs. pressure without preheating. 2. Up and down runs and blows now last about 3 and 2 minutes, respectively, thus keeping a more even temp. in the generator. 3. The blast is worked under 20 lb. pressure, and the length of the blow decreased, thus getting max. capacity for given investment and making towards good oil results. 4. With a high rate of blasting, careful provision for catching dust must be provided to prevent clogging of the checker work. 5. The installation of air and steam meters and thermo-electric pyrometers enables control of the process certain. 6. Proper selection of coal does not entirely do away with similar troubles. 7. The ash is easily fusible, it solidifies around the grate, while if it is difficultly fusible, the slag collects under up the walls of the generator. Automatic operation of a water gas set has been accomplished at Pensacola, Fla.

F. L. CALVERT.

Carbonate of potash for purifying gas. T. PETER. *J. Gas Lignite* 1915, 245-6 (1915, Dec. 16 no. 23, 57, 1915).—The dry purification of gas is becoming commonplace to gas managers, consequently they have exercised their skill in trying to supercede it. The result has been the finding of numerous processes or the use of HCN and Na_2S by the wet method. Preference is given to a salt of Na_2CO_3 on the reason that, during the whole course of the process no sediment is produced, the liquid remaining as clear as water. In the sequence of the purifying plant, the 3 washers are placed after the Na_2S washers. When our gas is treated with a Na_2CO_3 salt, the impurities are absorbed, and the gas leaves the washer in a purified state. The great merit claimed for the Peter system is the regeneration of the potash. Air passed through the acid salt, takes out the HCN and HCN , and the salt is again a working solution. Its production in equal is first established in the salt between Na_2CO_3 , Na_2S , and K_2CO_3 , the liquid thus becoming saturated; during regeneration the air takes out not only the HCN but also a part of the CO_2 . During chimney gases with the air and heating the salt liquid to 20°C . during regeneration will increase considerably the speed of the process. The solution is carried out with 100 lbs. water. The regeneration process is continued until a nitroprusside salt is fused with a nitric acid with the liquid.

J. V. JAMES.

Report of refractory materials research committee, 1914-5. I. J. COLLIER. *J. Gas Lignite* 1915, 277-285.—The members of the Refractory Committee representing the Institute of Mining and Metallurgy and the manufacturers have suggested the

matter of the removal of dust from "grog," and recommended no alteration in the specification that the "grog" employed in the manufacture of retort material must be free from dust and contain nothing that passes through the standard 16-mesh sieve (pieces of under $\frac{1}{32}$ inch linear dimension) prescribed by the Inst. Min. and Met.

B. W. GRIMES.

Benzene recovery from town gas supply. W. R. HERRING. *J. Gas Lighting* 131, 569(1915).—H. has studied the possibilities of recovering toluene from coal gas without depreciating the luminous or calorific value of the gas. At a small exptl. plant in Edinburgh he tried washing the gas in a Holmes rotary washer (1) with light grade coal-tar oil (sp. gr. 0.9862 and flash point 151° F.) and (2) with the same oil to which had been added 5% pure benzene (this mixt. distd. at 92° and contained no toluene). Using the washing oil not treated with C_6H_6 , the gas was reduced from 16.11 c. p. to 10.51 c. p. (or 34.7%) and from 585.3 B. t. u. (gross) to 559.1 B. t. u. (or 4.5%). With washing oil, treated with C_6H_6 , the gas was reduced from 16.08 c. p. to 15.06 c. p. (or 6.34%) and from 579.4 B. t. u. to 576 B. t. u. (or 0.58%). The most significant fact is that coal gas can be scrubbed of benzene and toluene with so little (4.5%) loss in heating value.

F. L. GROVER.

Formal order establishing 520 B. t. u. as Canadian standard. ANON. *Am. Gas Light J.* 103, 164(1915).—The Dominion Government sets standard calorific value of gas as 520 B. t. u. per cu. ft. of satd. gas, burned in satd. air, and the products of combustion leaving the calorimeter at substantially the same temp. as the factors enter. Vol. of gas is measured at 60° F. and 30 in. pressure. Penalties for gas below standard range from \$10 to \$80, according to the size of the company. In effect, July 1, 1915.

F. L. GROVER.

Flameless surface combustion of gases. L. SCHMIDT AND F. KRIEGER. *Z. Beleuchtungsw.* 21, 85-6(1915).—Owing to the comparatively high pressure required for successful operation, surface combustion burners have not met with much favor in the home. This obstacle has been overcome in the following manner (cf. Ger. Pat. 280,040; C. A. 9, 1841): The pores of a porous cap of asbestos or the like are coated with a catalytic agent such as Pt black; the cap is fitted to an ordinary bunsen burner fed with low pressure illuminating gas. The cap sets snugly and all gas must pass through the "catalytic" pores. After opening the cock the gas is allowed to pass through the pores for a few secs. Thereupon a match is applied; the flame soon disappears as the asbestos heats up. Readily combustible substances such as gasoline will not ignite when its vapors are brought into contact with the glowing cap; accordingly this burner is to be recommended for labs. where combustible liquids are used. The efficiency of the bunsen burner for heating purposes is decidedly increased by the addition of the asbestos cap.

C. G. FINK.

The Elswick works of the Newcastle-upon-Tyne and Gateshead Gas Co. ANON. *J. Gas Lighting* 132, 20-3(1915).—The  shaped, direct fired and hand charged retorts of the Elswick Gas Works have been replaced by producer gas-fired vertical retorts. Plans and elevations of the new vertical retort houses and accessories are given. Figures showing differences between the old and new systems are given.

F. L. G.

Some considerations as to calorific value and calorific standards. J. T. DUNN. *J. Gas Lighting* 132, 34-5(1915).—D. shows that the "Argand" burner test for c. p. deals unfairly with the poorer gases, and that the luminosity test is neither necessary nor sufficient. The heat energy derivable from combustion of a unit vol. of gas is the

only rational standard, since most gas is used in gas engines, for heating, or for lighting by incandescent mantles. The "gross" calorific value (heat derived from combustion starting with gas and air at 60° F., and ending with the products of combustion at the same temp.) is an arbitrary fig. and does not really conform to the way gas is usually burned, but it is constant for each sample of gas. D. also points out that the value of gas for incandescent mantles depends upon the heat value per unit vol. of the gas and air mixt., and this is approx. the same whether the gas be poor or rich.

B. W. G.

Blue water gas and deep fuel combustion. A. G. GLASGOW. *Trans. Intern. Gas Congress 1915; J. Gas Lighting 131, 705-6(1915)*.—Three laws of combustion may be developed as represented by the reactions: (1) $C + O_2 = CO_2$. (2) $CO_2 + C = 2CO$. (3) $2CO + O_2 = 2CO_2$. As commercially applied to gas manuf., deep-fuel combustion may be classified under 4 heads: (1) The continuous mfg. of industrial gas, in which incomplete-combustion products are used as a vehicle to convey the energy of the fuel to some point of useful application outside the generator. The gases must contain the max. amount of combustible CO. (2) Producer gas. This gas is the result of admitting to the bed of anthracite coal or coke a quantity of steam, so proportioned to the vol. of air that the desired temp. is maintained in the fuel-bed by a proper balance between the heat generated by the incomplete combustion with the O of the air to CO, and the heat absorbed by the decomposition of the steam to H_2 and CO. (3) The intermittent manuf. of water gas, in which the gas-making operation is frequently intermitted for a recuperating air blast, designed to restore to the fuel-bed the heat which has been previously extracted in decomposing the steam into water gas (H_2 and CO). (4) A "combustion" process, whereby any desired proportion of the heat energy developed during the air blast period is conveyed by the blast products to an extraneous point of application, while the remainder of such heat energy is stored in the fuel-bed for the subsequent decompn. of steam into H_2 and CO.

B. W. GRIMES.

The substitution of heating value for candle power as a standard of gas quality. R. S. MCBRIDE. *Trans. Intern. Gas Congress 1915 (adv. copy), 41 pp.* McB. shows that hardly 5% of the total gas consumed is in the open flame light, yet the candle power standard is only especially useful in detg. the quality of gas for this use. The quality of the 95% of the gas for the other uses depends almost entirely on the heating value, and its value should be judged by calorific tests. A gas of high candle power must also have high calorific power, but the converse is not true. The new system would be especially advantageous to the gas maker because of the greater ease of regular operation to meet the heat unit standard, and of the superiority in accuracy of heat measurements over candle power measurement. An economic discussion of the applicability of the heat standard follows.

F. L. GROVER.

A review of the present practices in the manufacture and distribution of gas by British undertakings. EDWARD ALLEN, W. B. DAVIDSON, J. FERGUSON-BELL, W. HOLR, F. W. GOODENOUGH AND J. BOND. *Trans. Intern. Gas Congress 1915 (adv. copy), 111 pp.*—This is a symposium consisting of five papers upon (1) condensation, washing, and scrubbing, (2) purification, (3) distribution, (4) sale, and (5) carbonization as practiced in the gas manufacture in Great Britain. Many photographs and drawings of English plants are inserted.

F. L. GROVER.

A coke oven expert's views on the recovery of benzene, toluene, etc., from coal gas. ANON. *J. Gas Lighting* 131, 502-3(1915).—The "expert" describes the theory and practice for recovering benzene and toluene from coke oven gas by the use of light creosote oils. The account is thorough and valuable. B. W. GRIMES.

The production and recovery of toluene from illuminating gas. ANON. *J. Gas Lighting* 131, 635-6(1915); cf. preceding abstr.—This question is rather a different problem for the coal gas engineer from what it is for the coke oven man on account of these considerations: (1) the necessity of leaving a certain quantity of benzene in the gas to give it the necessary calorific value and illuminating power and to prevent the deposition of $C_{10}H_8$, (2) the possibility of increasing the hydrocarbons in the gas without a decrease in the vol. of gas made per ton of coal carbonized, and (3) the best and most suitable method of recovery of the toluene which allows the benzene vapors to remain in the gas. After presenting the advantages and disadvantages of various methods of washing, the author concludes that creosote is commercially impossible for most coal-gas works. The "synthetic" process of Leo Vignon, in which lime is used as a catalyst in the carbonization of coal, presents great possibilities on the question of increasing the % of toluene in gas and tar, and lends itself especially to the "C" process of washing, at coal-gas works. During a 3 months' period at a medium-sized modern works using this process, increased yields and better quality have been noted in the production of gas, tar, coke, ammonia and toluene. B. W. GRIMES.

Weston-super-mare new gas works. ANON. *J. Gas Lighting* 131, 446(1915).—A compact detailed description is given of a modern gas works capable of producing 1,000,000 cu. ft. of coal gas per day, with provision for slight extensions which would increase the total output to 2,000,000. Mention is made of several commendable features. B. W. GRIMES.

Carbonizing mixtures of coal and coal dust. D. T. R. VAN LËNNEP. *J. Gas Lighting* 131, 520(1915).—From a mixt. of 80% of gas coal and 20% of fine dust a sufficient quantity of gas and a coke of good quality can be produced. The coke is better coked, less porous, and of greater resistance, and the gas has a higher calorific value than might have been expected. The distn. period is shorter than for gas coals only. The thorough mixing required is best obtained by first breaking the gas coal to a size of less than $1\frac{1}{2}$ in. B. W. GRIMES.

U-tube carbon dioxide indicator (CUNNINGHAM) 1. Determination of hydrogen in gas mixtures (BOSSHARD) 7. Electrical precipitation (DUSHMAN) 4. Estimation of traces of carbon monoxide in air (GAUTIER) 7. New filling material for gas washers (LUDWIG) 18. Gas *versus* electrically heated ovens (TROUT) 19.

Fuel for internal-combustion engines. T. FRANK. *Brit.*, 28,072, Dec. 5, 1913. It consists of 50% or less of one or more aliphatic hydrocarbons of high calorific value, such as peat oil, kerosene, or their distillates, and the unrefined carbinols produced from raw peat, i. e., fusel oil and the lower alcs. The carbinol and hydrocarbon are preferably mixed as vapors and condensed together. The peat may be treated in the app. described which comprises a disintegrator, a steam heater and agitator to reduce the mass to mud, a steam-jacketed vessel in which the mud is sprayed, agitated, and heated with acid to liberate suitable carbohydrates, and an autoclave. Subsequently, the mass is neutralized, fermented, pressed, and distilled in known manner.

Destructive distillation. OIL & CARBON PRODUCTS, LTD. *Brit.*, 15,368, June 26, 1914. In a process of effecting destructive distillation, condensable volatile products are sepd. from solid carbonaceous material such as coal, shale, or peat by moving such material under non-oxidizing conditions through a retort, the various regions of which

are maintained by indirect heating at temps. increasing from the end at which the material is introduced, and by causing the gases evolved from the various portions of the material to pass into contact with relatively cooler portions of the material in its solid or partly vaporized state, whereby condensed volatile matter is obtained in, and can be removed from, the retort in liquid form. The gases may be conveyed by a gaseous medium, which may be the washed and purified product from the retort. The temp. at the hottest part of the retort need not be more than about 600°. A suitable app. is specified.

Destructive distillation. R. F. STRONG. Brit., 15,980, Aug. 21, 1913. Peat, nut-shells, sawdust, shale, coal, or other carbonaceous materials are distd. in a series of superimposed retorts, the uppermost of which is a masticating retort. Cf. C. A. 9, 371.

Gas producer. E. FLEISCHER. Brit., 10,408, Apr. 27, 1914. Bituminous fuel, after passing through a preliminary distn. chamber, is preheated in a compartment before reaching the main combustion zone from which the hot gas is withdrawn by a main outlet pipe. Air is supplied at a point near the bottom, and a secondary supply of air, preferably mixed with steam, is admitted higher up and serves to burn that portion of the gas which passes through the compartment towards a secondary outlet; the hot combustion products serve to distil the fuel in the preliminary distn. chamber.

Coking. F. LAMPOUGH. Brit., 15,892, July 2, 1914. In an app. for the low-temp. distn. of coal, the coal is introduced into the system of retorts by an improved measuring hopper of the kind provided with an air-lock. The rate of supply through the hopper may be regulated by means of a variable speed gear.

Metallurgical coke. L. FRANCK. Brit., 28,941, Dec. 15, 1913. For a coke low in S, part of the usual lime addition to the coal before coking is replaced by a P compd. such as phosphorite, phosphate chalk, apatite, or vivianite. A further addition consisting of Mn ore such as MnO_2 may be made for the purpose of oxidizing the S compds. and causing them to be carried away by the gases. To increase the content of phosphide of Fe in the coke, Fe compds. may also be added.

Water gas. DELLWIK-FLEISCHER WASSERGAS GES. and P. KOSTER. Brit., 884, Jan. 12, 1914. In the process described in 304, 1914 (C. A. 9, 1686) after the fuel has been subjected to an air blast in a downward direction, steam is supplied at the bottom of the fuel bed, and steam and air at a point midway of the fuel bed, the water-gas outlet being at the top.

Drying peat. THOS. RIGBY. Can., 164,844, Sept. 14, 1915. A wet pulp of peat is digested under pressure sufficient to prevent ebullition until its H_2O is rendered freely expressible, the treated pulp is spread in a thin layer, suction is applied until it has acquired sufficient solidity for handling as a solid, and then it is further dried. Cf. C. A. 9, 3126.

Recording consumption of coal. M. BRESLAUER. Ger., 284,028, Oct. 15, 1913. The app. comprizes a tilting container set in the masonry work and serving to receive a feeding charge and deliver it into the fire box, together with a counting mechanism actuated thereby. During charging of the container the opening in the masonry work is closed on the fire box side, while the opening is closed at the outer surface during delivery of the charge to the fire box.

Briquetting. C. FOHR and E. KLEINSCHMIDT. -Ger., 284,789, June 20, 1913. Addition to 263,158 (C. A. 7, 3831). Briquetting with bituminous binders, according to the parent process, but with the use, instead of pitch, of other binders (asphalt, thick tar, resin) which are blown directly into the material to be briquetted after being atomized and dried to a powder by cooling.

Gas generator. A. BORMANN GEB. BLUMCHER. Ger., 284,702, Nov. 18, 1913. Constructional details of a generator with indirect gas heating.

Revoluble grate generator. J. PINTSCH, AKT.-GHS. Ger., 284,264, Mar. 27, 1914. The shaft and the revoluble grate are ring-formed.

Grate for gas generators. H. GORHTZ. Ger., 284,447, Mar. 24, 1914. A revoluble ash pit is provided.

Coke ovens. E. FUHRMANN. Ger., 284,039, Apr. 29, 1913. A device is provided for closing the discharge openings.

22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

F. M. ROGERS.

The light-sensitiveness of petroleum asphalt. PAUL GÖDRICH. Vienna. *Chem. Ztg.* 39, 832(1915); cf. *C. A.* 9, 3127.—Eight % solns. of hard pitch in C_6H_6 were filtered to remove the insol. C, and Zn plates were covered with a film by pouring the soln. over them and evapg. the C_6H_6 . Printing under a negative and developing in turpentine oil showed that only paraffin-free pitch is sensitive. Soft pitches gave no image. Sulfuring with S_2Cl_2 to 12% S destroyed the sensitiveness, in contradistinction to natural asphalt in which the sensitiveness is increased by S. Cf. *C. A.* 7, 1804. J. H. M.

Contributions of the chemist to the hardwood distillation industry. S. W. KATZENSTEIN. *J. Ind. Eng. Chem.* 7, 940-2(1915).—A part of the symposium at the Seattle meeting of the Am. Chem. Soc. E. H.

Contributions of the chemist to the naval stores industry. JOHN E. TREPLE. *J. Ind. Eng. Chem.* 7, 931-2(1915).—A part of the symposium at the Seattle meeting of the Am. Chem. Soc. E. H.

What chemistry has done to aid the utilization of wood. S. F. ACREE. *J. Ind. Eng. Chem.* 7, 913-5(1915).—An address delivered at the Seattle meeting of the Am. Chem. Soc. E. H.

Use of coal tar in creosote 20. Water in creosote 20. New filling material for fractionating towers (LUDWIG) 18. Deodorization of oil refinery waste (HESSER) 14. Oil regions of northwestern Mexico (GARFIAS) 8. Oil pools of Oklahoma and Texas (GARDNER) 8.

Benzine substitute. H. PLAUSON and P. SCHRÖDER. Brit., 4,340, Feb. 19, 1914. Brown coal or lignite is mixed with an equal proportion of a hydrocarbon, such as naphtha, a small amt. of alkali or alk.-earth nitrate is added, and the mixt. is sprayed into a distn. chamber in the presence of air and steam at a temp. of 600-700°. Low-boiling products are obtained.

Distilling mineral oil residues. W. SUMPF. Brit., 16,383, July 9, 1914. Mineral oil residues are mixed with peat dust, oily waste, and similar porous substances and are distd. at 900-1000°. The app. comprizes 2 retorts provided with perforated sheet metal containers running on rail-like ribs. The retorts are first brought to a bright red heat, and the charged containers are then inserted. The vapors pass from the upper retort to the lower retort by a pipe, and are collected from the lower retort by a perforated pipe.

Distilling mineral oil residues. W. SUMPF. Brit., 16,384, July 9, 1914. Mineral oil residues are mixed with refractory inorg. substances, such as wrought-Fe turnings, and are distd. at high temps. The turnings may be placed in a retort maintained at a

bright red heat, the residues being run into the retort continuously by means of a perforated pipe.

Cracking heavy hydrocarbons. E. GRAEFE and R. v. WALTHER. *Brit.*, 25,510, Nov. 7, 1913. The hydrocarbons are distd. under a pressure of about 20-30 atms. For this purpose an autoclave heated by a Pb bath may be employed, the pressure being obtained by closing a valve in the vapor outlet pipe during the initial heating, and afterwards adjusting the valve to maintain the pressure during the distn. The resulting gases and vapors may also be heated under pressure in a sep. large chamber in order to effect the combination of the H with the unsatd. hydrocarbons. A series of autoclaves may be used, the oil flowing from one to the other. The products are led to a condenser for the sepn. of gasoline, etc.; the uncondensed gases are gradually compressed for the successive sepn. of petr. ether and liquid illuminating gas, the residual uncondensed gas being used for heating, lighting, or power purposes.

Freeing cracked mineral oils from malodorous and resinifying substances. ALLGEMEINE GES. FÜR CHEM. IND. *Brit.*, 3,572, Feb. 11, 1914. This is effected by treatment with a salt of a heavy metal having a condensing action, such as SnCl_4 , ZnCl_2 , Fe_2Cl_6 , or CuSO_4 , and then distg. The oil and salt may be heated together, and the salt removed before distn. The residue left in the still is a viscid mass which ultimately solidifies to a glass-like mass.

Cracking hydrocarbons. L. HIRSCHBERG and POTENTIAL DEVELOPMENTS, LTD. *Brit.*, 4,573, Feb. 21, 1914. The voluminous Cr_2O_3 obtained by calcining Cr salts of volatile bases, such as NH_4 chromate or dichromate, is employed as the catalyst in the conversion of heavier hydrocarbons into lighter hydrocarbons. The process is effected by passing the hydrocarbon as finely divided liquid, or vapor, or gas, over the Cr_2O_3 at a dull-red heat. Other catalysts may be employed in conjunction with the Cr_2O_3 , e. g., Pt black, Ni, Cu, Pd, or Mn oxide, also carriers such as asbestos, silica wool, coke, fire-brick, etc. The hydrocarbon treated may be mixed with steam, H, air, or inert gas. Suitable hydrocarbons for treatment are: bituminous and mineral oils, such as crude oil, tars, tar oils, residuum oil, solar oil, paraffin oil, benzine, etc.; hydrocarbon waxes, such as ozokerite, paraffin wax, or ceresin; hydrocarbons from coal, etc., such as coal tar, bitumen, asphalt, water-gas tar, anthracene, creosote, naphthalene, etc.; gases containing hydrocarbon vapors, such as crude coal-gas or natural gas. The vapors resulting from the process are condensed and treated in any suitable manner by fractional distn., cracking, scrubbing, washing, refining, rectifying, etc. According to examples, light oil and gas are obtained from kerosene and creosote oil; also, according to the provisional specification, benzene is obtained from anthracene oil. Suitable app. is specified.

Atomizing burner. R. O. KEWITZ. *Ger.*, 284,293, Apr. 3, 1914.

Burner for liquid fuel. I. LERTORA. *Ger.*, 284,446, Jan. 25, 1914. The burner is provided with a multiple atomizing device which is operated by air or steam, and with a ring of exit nozzles which produces a spreading mixt. of combustible material. The pre-atomized mixt. is conducted through small nozzles, each of which extends, at an angle, into one of the delivery nozzles, wherein further atomization is effected.

Oil-fired heating furnace. GEBR. PIERBURG. *Ger.*, 284,738, July 8, 1914.

23. CELLULOSE AND PAPER.

A. D. LITTLE.

Sulfite waste liquors and their utilization. W. KIBY. *Chem. Ztg.* 39, 212-4, 261-3, 284-5, 307-8(1915).—In the usual processes for obtaining fermentable sugars

from wood by hydrolysis with acids under pressure, the sugar undoubtedly results from the hydrolysis of the cellulose of the wood. It is not conceivable, however, that fermentable sugars present in waste sulfite liquor could have been formed from the cellulose of the wood. Pressures higher than those used in the sulfite cooking process are necessary for the hydrolysis of wood cellulose and, furthermore, SO_2 is a poor hydrolyzing agent for cellulose. The fermentable sugar in waste sulfite liquor most probably is derived from other carbohydrates present in the wood and represents merely a residue of the sugar which was formed and again decomposed during the cooking process. It follows that proper regulation of the sulfite cooking process to decrease decomposition of sugars formed would have a favorable effect on sugar yields. A step in this direction is König's process in which a preliminary mild cook for the purpose of sugar production is followed by a more severe cook for the purpose of cellulose production. The earliest important processes for the production of alc. from waste sulfite liquor were those of Ekstrom and Wallin. The yields claimed by Ekstrom, namely, 115 liters abs. alc. per ton of cellulose, are higher than can be accounted for by the amt. of fermentable sugar in the waste liquors and are to be attributed to alc. fermentation of yeast food added. The Strehlenert, the Rinman and the Achenbach processes for the utilization of sulfite liquor are of importance. The Landmark process for the production of alc., which depends upon the freeing of the waste liquor from SO_2 , evap., neutralizing and fermenting with the addition of milk as a yeast food, possesses certain advantages but the rate of fermentation is exceedingly slow. Fermentation would be hastened by aeration. A by-product of this process is a ligno-casein containing 65% of casein, which is stated to be suitable for paper size. The residue, after fermentation, is dried for fuel purposes. Generally speaking, no utilization of waste sulfite liquor can be considered complete unless full recovery is made of the sugars present. Economic operation requires (1) concn. of liquor, (2) fermentation, (3) distn. in well designed still. Operation and performance of a suitable still and rectifier is described in some detail.

V. NUNEZ.

Toughening action of nitric acid upon filter papers. CLAYTON BEADLE. *Chem. News* 112, 143-4 (1915).—The tips of filter papers may be very conveniently toughened to resist filtration by suction by placing them in a dry funnel and treating them with a small vol. of HNO_3 (d. 1.42) for a few seconds. When filter papers are toughened all over in this manner the rate of filtration is but $\frac{1}{3}$ that of the untoughened. When the apex only is toughened, the rate of filtration is at first much higher than that of the untoughened paper but is lowered to an equal value when water is filtered. V. N.

Alkali cellulose. COURTAULDS, LTD. and L. P. WILSON. Brit., 14,675, June 18, 1914. The treatment with oxidizing agents, as described in 13,055, 1914 (C. A. 9, 3130), is assisted by the addition of a catalyst, such as the oxides or hydroxides of Fe, Ni, and Co. *E. g.*, wood pulp is soaked in FeSO_4 soln., pressed and dried; the mass is then treated with NaOH soln. in the usual way, and allowed to oxidize in the usual boxes, or by treating with a current of air. Or wood pulp is treated with NiSO_4 soln., pressed, and dried; the mass is then treated with NaOH soln. containing Na_2O_2 . The products obtained by these treatments may then be treated with CS_2 for the production of the xanthate.

Boiling cellulose. J. O. LUNDBERG. Ger., 284,628, June 4, 1914. An app. is specified for use in carrying out the process of boiling cellulose, by the sulfate treatment, with the employment of preheated boiling liquor.

Solutions of cellulose acetate. BADISCHE. Ger., 284,672, Jan. 16, 1914. Cyclohexanone and its homologs may be employed to advantage as solvents in the manuf. of varnishes of nitrocellulose. Cyclohexanone has been found suitable also for the soln.

of cellulose acetate sol. in acetone or only softened by acetone. The soln. of cellulose acetate in cyclohexanone may be dild. directly with benzene and its homologs, but a small addition of acetone permits also the use of this diluent or its homologs, so that cheaper solns. can be obtained. *E. g.*, a lacquer is obtained by dissolving 1 part of acetone-sol. or acetone-softened cellulose acetate in 50 parts of cyclohexanone. The soln. can be used for finishing wood, metal, etc. For dipping, 1 part cellulose acetate is dissolved in 25 parts of cyclohexanone, and this soln. is dild. with 25 parts of a mixt. of 3 parts acetone and 8 parts of toluene. Cf. *C. A.* 9, 3359.

Cardboard with glossy surface. E. BERGERHOFF. Ger., 284,527, Sept. 27, 1914. The surface to be treated is covered first with a sheet of paper or other material of a transparent nature or rendered transparent by satn. with oil or fat, whereupon varnish is applied to the surface of the transparent layer. By reason of the action of the oil or fat on the paper, the pores of the latter are closed completely so that the varnish, while adhering firmly, nevertheless does not penetrate.

24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE.

Contributions of the chemist to the explosives industry. CHARLES E. MUNROE. *J. Ind. Eng. Chem.* 7, 945(1915).—A part of the symposium at the Seattle meeting of the Am. Chem. Soc. E. H.

Comparative action of explosives. I. Introductory. A. STETTACHER. *Z. ges. Schiess-Sprengstoffw.* 10, 193-5(1915). II. "Initial" and "brisant" explosives. *Ibid* 214-6.—Definite weights of fulminate of mercury, lead azide, and tetranitromethylaniline were detonated and the explosive action and pressure detd. from the effect on an iron base. The tetranitromethylaniline had the strongest splintering and deforming action and lead azide the least. In a similar manner comparison was made of the intensity of explosion for tetranitromethylaniline, picric acid, fulminate of mercury, lead azide and a mixt. of fulminate of mercury and KClO_3 . The "brisant" explosives showed the greatest effect on the iron base. Of the "initial" explosives, only fulminate of mercury showed any impression on the base. In a 3rd expt. tetranitromethylaniline, trinitrotoluene and silver azide were fired under identical conditions. The trinitrotoluene made a large hole in the iron support whereas the silver azide made only a very slight impression. III. Pressure effect of nitroglycerin and the aromatic nitro compounds. *Ibid* 229-32. From the decompn. reaction of nitroglycerin, trinitrotoluene, and tetranitromethylaniline it is seen that the largest fraction of the total energy is set free in the explosion of nitroglycerin. Nitroglycerin decomposes more slowly than either of the others but gives a higher heat of decompn. Trinitrotoluene is second in speed of detonation and lowest in heat evolution. The intensity of the explosion of trinitrotoluene is not affected by covering with sand or water but is increased by admixture of KClO_3 . O. L. THOMAS.

Loading of percussion caps for projectiles. O. HAGEN. Dresden. *Z. ges. Schiess-Sprengstoffw.* 10, 177-8, 195-7, 210-14, 232-5, 267(1915). R. P. CALVERT.

Explosion on the "Benedetto Brin." *Z. ges. Schiess-Sprengstoffw.* 10, 276(1915).—The explosion is thought to have been produced by spontaneous combustion of nitrocellulose or nitroglycerin powder on board the ship. The article gives a review of recent marine explosions which may be attributed to the same cause. R. P. C.

Nitrocellulose explosives. C. CLAESSEN. Brit., 24,713, Oct. 30, 1913. Nitrocellulose is gelatinized by means of not more than 30% of nitro compds. of benzene,

toluene, or phenol without the use of volatile solvents, the gelatinization being effected by heat and rolling pressure. The product can be molded.

Blasting detonators. J. HARLÉ. *Brit.*, 15,355, June 26, 1914. Detonators for string-like fuses, the tubular cover of which may be metallic or textile, are composed of tetranitropentaerythritol, alone or mixed with other ingredients. The other ingredients may be nitrobenzene, nitrotoluene, trinitrotoluene, nitrophenols, or nitrated amines.

Charges of fusible explosives. G. ISSLER. *Brit.*, 29,152, Dec. 17, 1913. The molds, while in a vertical position, are filled with the fused explosive, and then caused to rotate about a vertical axis, and under the centrifugal action, to assume a more or less horizontal position, whereby the charge is simultaneously cooled and compressed, solidification beginning at the outer end.

Waterproof blasting cartridges. S. LASZCZYNSKI. *Brit.*, 16,208, July 7, 1914. Waterproof paper cartridge cases are made by passing the overlapping longitudinal edges of the paper between 2 seam-crimping wheels after the manner of cigaret tubes, similarly crimping the overlapping folded or star-shaped edges of 1 end of the tube, then stiffening this end by a coating of chrome-glue soln. dried after its application, and finally dipping the whole case into linseed-oil varnish. The explosive charge, when of the "Sprengel" type, is contained in a paper wrapper perforated to facilitate impregnation, and made of slightly smaller diam. than the internal diam. of the case to permit easy insertion and removal of the charge.

25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

Progress in the field of artificial organic colors in the year 1914. L. LEHMANN. *Chem. Ind.* 38, 205-11, 251-7 (1915).—A review of patents. F. W. SMITHER.

Coal-tar dyes and the Paige bill. BERNHARD C. HESSE. *J. Ind. Eng. Chem.* 7, 963-78 (1915).—An address. E. H.

Dyeing artificial silks. ERNEST C. T. BICK. *Textile World Record* 49, 119-20 (1915).—Dyeing of artificial silks varies in many particulars from the dyeing of vegetable fibers. For bleaching the usual methods for cotton may be employed, especial care being taken that no Cl is left in the material. In dyeing Chardonnet silk with basic dyes, it is unnecessary to mordant previously with tannin or Sb salts, unless special fastness to washing or acid is required. In this process the bath is first charged with 5-10% AcOH, the skeins given several turns in this, removed, the dyestuff added, the skeins returned and the bath gradually heated to 77°. Viscose and cupro-ammonium silks are mordanted with 2-4% tannic acid and 0.5-1% HCl for 2 or 3 hrs. at 49° and fixed in a bath containing "half the amt. of Sb salts as tannic acid used." The dyeing is done as described for Chardonnet silk. In applying other methods for dyeing cotton to dyeing artificial silk, it is necessary to add 1-2% of sulfonated oil to increase penetration and soften the thread. The temp. is kept below 77°. When special fastness is desired, vat colors are used, or the shade is obtained by producing insol. azo colors on the fiber. The latter method is carried out by padding the hanks, 2 lbs. at a time, in a receptacle containing an alk. soln. of naphthol A S and turkey red oil; then after whizzing, padding 2 lbs. at a time in a diazotized soln. of fast red G base. The fastness to light, Cl, and acids of goods dyed by this process is even better than by alizarin red. Artificial silk containing oil must be scoured before dyeing. L. W. RIGGS.

Acid "tendering" of cotton cloth. J. H. LESTER. *J. Soc. Chem. Ind.* 34, 934-6 (1915).—Expts. were made with strips of cloth 2.5 in. wide, tested on a Goodbran

machine adjusted to 6 in. between the clamps. Samples were treated with HCl or H₂SO₄ of various strengths and dried by ironing. The degree of tenderness caused by the 2 acids is about the same. The max. amt. of free HCl allowable in cotton cloth appears to be 0.01%. Only the severest tests, such as ironing before laundering, show this amt. of acid to have any tendering effect. In some cases, dependent upon the future use of the goods, a larger amt. of acid may be tolerated, but always less than 0.1%.

L. W. RIGGS.

A gaseous-conductor lamp for color matching. D. McFARLAN MOORE. *Elec. World* 66, 1160(1915); *Elec. Rev. West. Elec.* 67, 949(1915).—The lamp consists of a straight glass tube in an elongated sheet-metal case with screw mogul base for the ordinary lighting circuit. CO₂ is generated automatically within the tube itself, a small bulb about 1 in. long near each electrode and containing CaCO₃ supplying the gas when resistance wires embedded in the CaCO₃ become heated to the proper degree through a shunt connection. The gas column, 1 ft. long and 7/8 in. in diam., appears as a solid bar of light of intense whiteness. Available foot-candles near the tube total more than 200, thus making the app. suitable for the very closest color discriminations. The degree of vacuum is automatically held to 0.001 mm. of Hg and the app. will stand wide line-voltage fluctuations without disarrangement. The app. is particularly useful for correct color matching in the night shifts of the dye and textile industries. Diagrams and spectro-photometric curve of the CO₂ spectrum are given. [The full paper will appear in *Trans. Illum. Eng. Soc.*]

I. C. MATTHEWS.

Production of silk in the larvae of *Bombyx mori* (FIGORINI) 111. Resinates for preserving wood and textiles (VAN VLOTEN) 26. Conversion of the natural flavone coloring matters into pyranol dyes (WATSON) 10. Some aminoazoimido bases and their azo dye derivatives (KYM) 10.

Dyes. S. HEAP & SONS and W. MARSHALL. Brit., 15,820, July 2, 1914. Artificial silks are first prepd. with tannin materials and then dyed with basic dyes; the dyeings may be after-treated with metallic salts. According to an example, the material is prepd. with tannic acid, dyed with methylene blue, and after-treated with tartar-emetic. The process may be applied to hanks or piece goods, or to mixed fabrics containing artificial silk and cotton, etc.

Dyes and intermediate products. SOC. OF CHEM. IND. Brit., 15,949, July 3, 1914. Indamines are obtained by condensing with carbazole, or its *N*-alkyl or *N*-aryl derivs. or nuclear substitution products thereof, arylsulfiminooarylenechloroimides of the benzene or naphthalene series in the presence or concd. H₂SO₄; the product obtained from *p*-toluenesulfiminophenylenechloroimide is specified. Leucoindamines are obtained by reducing the above described indamines. Sulfuretted dyes are obtained by heating the above described indamines or leucoindamines with alkali polysulfides in the presence or absence of Cu or Cu compds. Products sol. in alkali sulfides and products insol. or difficultly sol. in alkali sulfides but sol. in hyposulfite vats are obtained; both series of products dye cotton blue shades. *p*-Toluenesulfo-*p*-phenylenediamine and 1-*p*-toluenesulfamino-2-Cl-4-aminobenzene are converted into the corresponding chloroimides by treatment with Na hypochlorite and Cl, respectively.

Vat dyes. BADISCHE. Brit., 26,690, Nov. 20, 1913. Vat dyes are obtained by subjecting to the action of an alk. melt naphthalene-1,8-dicarboxylic imide, or a halogen or a *N*-alkyl or *N*-aryl deriv. thereof, or acenaphthenequinone mono- or dioxide, or a halogen deriv. thereof. The dyes may be subsequently halogenated; or those derived from naphthalene-1,8-dicarboxylic imide itself, or its halogen derivs.,

may be alkylated or arylated, or may be first halogenated and then alkylated or arylated.

Vat dyes of the anthracene series. BADISCHE. Brit., 1,425, Jan. 19, 1914. The vat dyes obtained by treating anthracene-1,9-dicarboxylic imide, or a halogen deriv. thereof, with an alk. melt, are subsequently alkylated or aralkylated in the imido group.

Azo dyes. BAYER & Co. Brit., 21,932, Sept. 29, 1913. The dyes are obtained by combining diazo, diazoazo, or tetraazo compds., or intermediate products from 1 mol. of a tetraazo compd. and 1 mol. of an azo dye component, *e. g.*, benzidineazosalicylic acid, with the condensation products from aminonaphthols or their sulfonic acids and sulfonyl chlorides of *o*-phenolcarboxylic acids described in 22,854, 1913 (C. A. 9, 2152).

Secondary disazo dye. KALLE & Co. AKT.-GES. Brit., 4,656, Feb. 23, 1914. The diazo compd. of 1-naphthylamine-2-sulfonic acid is combined with α -naphthylamine, rediazotized and combined with 2-amino-5-naphthol-7-sulfonic acid in alk. or neutral soln. The product dyes cotton violet shades, becoming blue on diazotization on the fiber and development with a naphthol.

Primary diazo dyes. BAYER & Co. Brit., 29,567, Dec. 22, 1913. The diazo compds. of *o*-aminophenols or their substitution products are combined in alk. soln. with the monoazo dyes produced by combining diazotized anthranilic acid or homologs or substitution products thereof with 2,5,7-aminonaphtholsulfonic acid or its alkyl or aryl derivs. in such a manner that the azo group is in the same nucleus as the amino group.

Sulfuretted dyes. AKT.-GES. FÜR ANILIN-FABRIKATION. Brit., 15,752, July 1, 1914. Sulfuretted dyes are obtained by heating with S or a polysulfide, mixts. of a nuclear alkyl deriv. of 4-hydroxydiphenylamine and a compd. yielding an amine on reduction, preferably a nitro, azo, or azoxy compd.

Preparing fibers for spinning. C. SUTTIE. Brit., 16,183, July 7, 1914. The *Phormium tenax* or other like fiber-bearing leaves or stalks to be treated are gripped in holders carried by an endless band and traversed across the face of a drum comprizing 2 sets of blades sepd. by a plain portion. While passing the plain portion, each holder is turned to present a fresh length of material to be treated, and means are provided for opening and closing the holder and changing the position of the grip of the holder on the material.

Fibers from papyrus. P. HOKRING. Brit., 6,971, Mar. 19, 1914. The papyrus is cut to lengths of about 10 in., torn up in machines similar to rag engines used in paper mills, and heated for several hrs. with H_2O at 40–50°, fresh H_2O being supplied 2 or 3 times. The material is then pressed and heated in H_2O to which has been added an emulsion of fatty matter, such as castor oil or oil of palm kernels. The longer fibers are sepd. from the shorter fibers by straining, and, after drying, they are broken, combed, and heckled, and then converted into threads in known manner. The short fibers may be used for paper making. Old or dried reeds may be heated under pressure.

Fabric for aviation apparatus. BRITISH EMALLITE CO. Brit., 1,049, Jan. 14, 1914. A fabric invisible or indistinctly visible is formed of films of cellulose acetate or like compd. Materials are added to modify the refractive index of the compd. so as to render invisible a reinforcing material, such as silk or cotton fibers placed between the sheets. In an example, a compn., comprizing 110 g. of acetate or hydroacetate of cellulose, 35 g. of a mixt. composed of equal parts of β -naphthol, Et ether of β -naphthol, and benzenesulfonamide, 880 g. of C_2H_5Cl , and 120 g. of alc., is spread on glass, and very fine silk tulle placed upon it while still moist. This is stripped off when dry and placed, tulle side downwards, upon a second moist layer of the compn. spread on glass, and, when dry, the completed fabric is removed from the glass.

Coating fabric with an adhesive material. F. STOFFEL. Brit., 15,262, June 25, 1914. The process is effected without modifying the properties of the fabric. Gelatin, in a pasty or thick liquid condition, is applied to the back of the fabric by means of an air spray. The expansion of the compressed air causes cooling, coagulation, and almost complete drying of the particles of adhesive before reaching the fabric.

Anthraquinone. CHEM. FABRIK GRIESHEIM-ELEKTRON. Ger., 284,083, Feb. 15, 1914. Addition to 283,213 (C. A. 9, 2599). Cf. C. A. 9, 2986.

Anthraquinone. CHEM. FABRIK GRIESHEIM-ELEKTRON. Ger., 284,084, Mar. 19, 1914. Addition to 283,213 (C. A. 9, 2599). The HNO_3 specified in the parent specification (cf. *supra*) may be substituted by Cl and N oxide compds.

Anthraquinone. CHEM. FABRIK GRIESHEIM-ELEKTRON. Ger., 284,179, Mar. 28, 1914. Anthraquinone and its derivs. are manufd. by acting on anthracene or its derivs. with NO_2 in the heat and in the presence of solvent or diluent with the addition of Hg salts.

Tetrachlorodihydroanthracenes. FARBW. V. M. L. & B. Ger., 283,106, Nov. 16, 1912. To obtain the pure 9,9,10,10-tetrachloro compd. and the pure 2,3,9,10-tetrachlorodihydroanthracene, anthracene or 9,10-dichloroanthracene is treated at a low temp. in CHCl_3 or $\text{C}_2\text{H}_5\text{Cl}_4$, or at a higher temp. in benzene, toluene, or other hydrocarbons, with Cl. Both of these products serve as initial material in the manuf. of tech. valuable intermediate products.

Bleaching fiber. DEUTSCHE GOLD- UND SILBERSCHNEIDE-ANSTALT V. ROESSLER. Ger., 284,761, Feb. 21, 1913. The fibrous material is bleached with alk. solns. evolving O.

Fulling animal fibers. TEXTILTECHNISCHES BUREAU INH. ARNO LEHMAN. Ger., 284,694, Nov. 4, 1914. Solns. of malt, malt preps. (such as diastafor), glucose, and grape sugar, but especially the highly diastatic malt preps., have been found to possess strong felting properties, and they find application, alone or in combination with soda, soap, etc., for fulling animal fibers. The action depends upon a marked softening of the fibers which materially facilitates felting, so that the fulling process is shortened about $\frac{1}{3}$ the time formerly required. E. g., for the treatment of 120 kg. of over-coating, 2 kg. fulling soap (64% fat content), 3 kg. calcined soda, 0.400 kg. diastafor (extra strong), are dissolved in 140 liters of luke-warm H_2O ; the material is sprayed uniformly for 2 hrs., with this soln., while it is on the fulling machine.

Preparing nettle plant fiber for spinning. O. RICHTER and F. PICK. Ger., 284,704, Feb. 7, 1914. The pectin lamellae enclosing the bark fiber is destroyed by macerating the bark removed from the plant, at 30-40°, in 5-27% NH_3 soln., heckling the freed fiber in the dry or wet state, then cooking it for 1 hr. in a soap bath, and finally again crushing and heckling the mass in the dry or wet state. The pectin lamellae can be destroyed also by extg. the green or dry and softened bark, after removal from the plant, with ordinary H_2O for 2-3 hrs., to remove the contained sugars, and then retting it for 10-72 hrs. After extg. the sugar, the mass may be heckled while wet, or dried and crushed and then heckled. Fruit sugar can be obtained from the ext. liquor as a byproduct.

26. PAINTS, VARNISHES AND RESIN.

A. H. SABIN.

Contributions of the chemist to the paint and varnish industry. MAXIMILIAN TOCH. *J. Ind. Eng. Chem.* 7, 938(1915).—A part of the symposium at the Seattle meeting of the Am. Chem. Soc.

E. H.

Contributions of the chemist to the lead industry. G. W. THOMPSON. *J. Ind. Eng. Chem.* 7, 937-8(1915).—A part of the symposium at the Seattle meeting of the Am. Chem. Soc. E. H.

Iron oxide reds. ANON. *Farben-Ztg.* 21, 9-11(1915).—A general article on prepn., use, etc. E. W. BOUGHTON.

Is the old name "boiled (gekochte) linseed oil" applicable to modern resinat oil? C. NIEGEMANN. *Farben-Ztg.* 21, 12-3(1915).—Continuation of the discussion of this question (cf. *C. A.* 9, 1848). E. W. BOUGHTON.

What is pure boiled linseed oil? ANON. *Farben-Ztg.* 21, 11-2(1915).; see preceding abstr. E. W. BOUGHTON.

Protecting bright articles from rust. A. L. HASS. *Am. Machinist* 43, 770(1915).—As a preventive to rust formation on machines and other articles which are shipped for some distance, H. mentions the old method of coating with lead and tallow; due to the acidity of the tallow, such a coating must be removed at the earliest opportunity. A new method as adapted to buckles, rings, and harness fittings has given excellent results. Cheap varnish dild. 2 or 3 times with methylated spirits and made up when required is put into an oil drum, minus 1 end, of 6³/₄ to 10 gal. capacity and 12 in. in diam. so that the drum is ¹/₄ full. Articles to be treated are placed in a smaller drum similarly constructed, and are thus immersed. The smaller vessel is removed and the articles, shot out on a wire draining surface, are ready for packing in 15 min. The process is cheap, effective in bulk, coating does not alter the goods, and is a protective coating against tropical temps. I. C. MATTHEWS.

Rust prevention and protective coatings. M. BOTTLER. *Kunststoffe* 5, 232-4(1915).—A brief discussion of corrosion, together with a review of patented coating processes. F. W. SMITHER.

Electrically heated japanning ovens. C. F. HIRSHFELD AND W. D. DYGERT. *Elec. World* 66, 930-2(1915).—Data on the construction and operation of large elec. ovens. C. G. F.

Resinates for preserving wood and textiles. H. K. VAN VLOTEN. *Chem. Weekblad* 12, 160, 483-4(1915).—Most of the soln. for the impregnation of wood are sol. in water and therefore less efficient than the insol. soaps. The author calls attention to the resinates, which he considers as preferable, on account of their insolubility in water and reasonable price. As a solvent, linseed oil and resin oils of different fractions may be used, especially when only protection against the influence of the weather is required. Cu and Hg resinates, dissolved in gasoline, turpentine, kerosene, etc., may be applied as a protection against moisture and, on account of their poisonous nature, against damage by insects. Textiles may be impregnated in the same way.

J. T. FLOHIL.

Binder for pigments. CHEM. TECH. FABRIK J. LORENZ & Co. Aust., 2,655, Mar. 20, 1914. Carnauba wax or montan wax, or a mixt. of both, with or without the addition of stearin or NH₄OH, is saponified to obtain a dough-like mass, then mixed with a pulverulent mixt. of casein and borax, whereupon the required softening of the mass is effected by means of the usual oil or varnish additions. Finally the product is dried and ground in order to obtain a powder which may be incorporated readily with water-color solns.

Painters' size. F. BECKMANN. Brit., 4,567, Feb. 21, 1914. The size consists of 100 parts CaO and 50 parts sugar, with the addition of potato flour and dextrin to render the mixt. more easily miscible with H₂O, and to prevent the formation of lumps.

Varnish or linoleum masses. REICHOLD, FLÜGGER & BOECKING. Brit., 15,595. June 29, 1914. See Ger., 282,959 (C. A. 9, 2460).

Phenol-aldehyde resins; varnishes. CHEM. FABRIKEN DR. K. ALBERT and L. BEREND. Brit., 15,875, July 2, 1914. Phenol-aldehyde resins are rendered sol. in fatty oil by melting with natural or artificial resins or fatty oils or a mixt. thereof; colophony, wood oil, turpentine resin, copals, cumaron resins, and hardened and esterified resins may be employed. The phenol-aldehyde products used may be either fusible or infusible when heated alone. The resins or fatty oils may be added to the reaction mass before or during the manuf. of the phenol-HCHO resins. Oil varnishes are prepd. by heating the oil-sol. product with fatty oil until a soln. is obtained which is clear in the cold state and is not clouded by addition of benzine or turpentine oil.

Resinous condensation products. HEINEMANN, H. C. HARVEY and H. W. ROBINSON. Brit., 28,187, Dec. 6, 1913. Phenol or cresols and HCHO or its polymers are first heated without a condensing agent to yield a liquid oxybenzyl alc., and this product is further heated in an open vessel with SO_2 soln. The product can be rendered insol. by further heating or treatment with a basic catalyst.

27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

Preparation of the Wijs iodine solution. W. FAHRION, Stuttgart; HUGO DUBOVIKZ, Budapest; C. NIEGEMANN, Cologne. Chem. Ztg. 39, 744(1915).—A discussion. Cf. C. A. 9, 2820. J. H. MOORE.

Contributions of the chemist to the art of soapmaking. MARTIN H. ITTNER. J. Ind. Eng. Chem. 7, 935-6(1915).—A part of the symposium at the Seattle meeting of the Am. Chem. Soc. E. H.

Yeast fat, a new source of fat. A. WELTER. Seifenfabrikant 35, 845-6(1915).—Delbrück and his workers in Berlin have discovered a process of making protein from sugar by the addition of NH_4 salts and certain yeasts. It is already possible to make yeast contg. 50% protein which is well suited for fodder. This yeast is found to contain up to 4% fat which can be increased. Lindner of the Inst. of Fermentology, Berlin, has produced yeast organisms which contain 17% of fat on the dry basis. The fat extd. from yeast is liquid and produces a good curd soap. It is thought that the fat is produced by a transformation of the sugar. The question of digestibility is being investigated by Voltz. E. SCHERUBEL.

English export soaps. J. DAVIDSOHN. Seifenfabrikant 35, 814-5(1915).—Analyses of a blue mottled and a yellow soap. The former was made from 50% coconut and 50% peanut oil and is filled with 13% of $\text{Na}_2\text{Si}_4\text{O}_9$. The yellow soap was made from coconut or palm kernel oil filled so as to contain 27 to 28% $\text{Na}_2\text{Si}_4\text{O}_9$; it was colored with aniline dye. E. SCHERUBEL.

Bone grease and its preparation for use in the soap industry. Q. ROSANER. Seifenfabrikant 35, 815-6, 829-30(1915).—A discussion of well-known methods of handling this substance. E. SCHERUBEL.

The chemist and the packing-house products industry (LOWENSTEIN) 12.

Albumin from oil press residues. V. GRAFE and K. PECHE. Aust., 9,908, Nov. 20, 1913. The malodorous oils, fatty acids, and their decompn. products, contained in the residues, are removed by sapon. and washing, whereupon the residues are extd. by albumin solvents.

A fodder base and albuminous matter from oil press residues. V. GRAFE and K. PRACH. Aust., 6,090 and 7,789, July 24 and Nov. 24, 1914; cf. 9,908, *supra*. After sapon. of the oils and conversion of the fatty acids into soaps, the albumin in the alk. soap soln. is sepd. by neutralization. The sapon. of the oils and fatty acids is effected by oxides or hydroxides of polyvalent metals such as the alk. earth metals, which form insol. soaps, whereupon the granular soap ppt. is sepd. by straining from the albumin.

Hydrogenating fats. - C. ELLIS. Brit., 16,600, July 11, 1914. In the hydrogenation of fatty bodies, such as edible oils, H is bubbled through the melted fat in the presence of a catalyst, and the fat is moved in a direction across the path of travel of the H current. A suitable app. comprizes a closed reaction vessel for holding the fat, provided with a pipe at the bottom for introducing H. The oil is agitated and moved more or less horizontally by propellers carried by a rotating shaft, and contact between the H and the fat may be increased by stationary baffles or screens arranged to alternate with the propellers, and by bells mounted on the rotating shaft. The catalyst may be mixed with the oil and may consist of a catalytic metal either alone or on a carrier; or it may be introduced as NiCO with the H.

Continuous hydrogenation of unsaturated fatty acids, or esters thereof. BADISCHE. Brit., 2,307, Jan. 28, 1914. As catalyst is employed Ni, Co, or Fe, or mixts. of these metals with one another or with agents promoting the activity of the catalyst. The process is effected under pressure of at least 30 atms. and preferably over 50 atms., the catalyst being supported in the pressure vessel so as not to mix with the substance treated. The prepn. of the catalyst may be effected by reduction of an O compd. of the metal by means of H under pressure in the app. which is subsequently used for the hydrogenation of the fatty acid, etc. According to examples: finely divided Ni, prepared by reduction of the oxide or carbonate at a low temp., is supported on a carrier in the pressure vessel, or Ni pieces, wire netting, or wool is suitably held therein, and cottonseed or linseed oil is passed into the vessel and treated with H at 100° under a pressure of 120 atms.; NiCO₃ or Ni(OCO.H)₂, mixed with Al₂O₃ and formed into balls or spread on a carrier, is placed on perforated trays in a cylindrical high pressure app., and reduced at 220-250° by means of H under pressures of 30-100 atms., the reduced metal is allowed to cool in the atm. of H to about 80°, and a stream of the oil to be hydrogenized and H under pressure are then introduced into the app.

Catalytic hydrogenation and dehydrogenation of carbon compounds. BADISCHE. Brit., 2,308, Jan. 28, 1914. These processes are effected in the presence of metallic Fe, Ni, Co, or Cu, mixed with a compd. of F, Te, or Sb. The F, etc., compd. may be mixed with a compd. of the catalytic metal, or a compd. of the catalytic metal may be soaked in a soln. of the added compd. or an insol. fluoride. A compd. may be pptd. in the presence of a compd. of the catalytic metal. The catalytic metal may be in finely divided or compact state, and carriers may be employed. According to examples: NiCO₃ is mixed with Na silicofluoride soln., and the product is dried, reduced by H, and employed in the hydrogenation of linseed oil; Al, Ca, or K silicofluoride, BaF₂, Ca borofluoride, or K Ti fluoride may be used; Ni wire netting is cleaned with dil. HNO₃, treated with NH₄ silicofluoride soln. and Al(NO₃)₃, dried, and reduced; NiCO₃ is soaked in a soln. of NH₄ tellurite, or K pyroantimonate, and the product is reduced and employed in the hydrogenation of cottonseed oil or mineral oils.

Hydrogenation of fats and oils. J. DEWAR and A. LIEBMANN. Brit., 15,668, June 30, 1914. The fats and oils are treated with H in the presence of a catalyst distributed over a mass or fibrous and coherent material or yarns or fabrics made therefrom, and arranged so that the fibers will not become sepd. from one another. With this arrangement the tedious operation of filtration is avoided. The fibrous material

may consist of cotton, hemp, flax, or jute, wool, silk, or similar natural organic fibrous materials, or even artificial silk, *e. g.*, viscose silk freed from S. Sponge also may be used. Sepn. of the fibers is prevented by enclosing the masses between screens of gauze or other suitable material, or by securing with wires or threads; or if yarns or fabrics are used, these may be wound round or otherwise secured to the blades of an agitator or to fixed supports. If strongly adherent masses of fibrous materials, such as cotton, silk or flax, or yarns or fabrics made therefrom, be used, the masses may be left free to move in the liquid, but the products of hydrogenation are not so satisfactory. If Ni, Co, or Cu is used as the catalyst, the oxide or carbonate of the metal is distributed on the support, and the catalyst produced before or during the process of hydrogenation. In the latter case, it is advantageous to proceed according to the process described in 12,982, 1913 (*C. A.* 8, 3869), in the case of the Pt group metals, the additions being effected by impregnating the materials with a Pt or like salt soln., and then treating with a hot alk. soln. of HCHO. In examples, cotton or linen yarn, or bleached artificial silk yarn freed from S, or asbestos cord is passed through a soln. of Ni and Cu carbonates, and after squeezing, treated with soda soln. and dried. The material is wound on a Ni gauze cylinder or on the blades of the agitator, and placed in an autoclave with the oil. In another example, silk yarn, on which Ni and Cu carbonates were distributed as in the previous examples, is wound on the plates of an agitator and washed, first with H₂O, then with Ni acetate soln., and finally with H₂O.

Disinfecting soaps. SCHÜLKE & MAYR NACHFOLGER, DR. RAUPENSTRAUCH. *Brit.*, 20,818, Sept. 15, 1913. Liquid or solid disinfecting soaps sol. in H₂O are produced by adding *p*-chloro-*o*-cresol, mixed or not with *p*-chloro-*m*-cresol, to soaps after or during sapon. The combination may be assisted by the addition of EtOH, glycerol, or other alc., and H₂O. Castor oil potash soaps mixed with soaps made from palm-nut, coconut, earth-nut, or rape or like oils are preferred, but soda or resin soaps may be used. *p*-Chloro-*o*-cresol of the high degree of purity required may be obtained as white felted needles *m.* 50–51° and *b.* about 230°, by treating 108 kg. of *o*-cresol with 71 kg. of liquid SO₂Cl₂ in the cold or at a temp. sufficiently low to prevent side-chain substitution, washing with H₂O to remove inorganic products, slowly distilling off with steam the *o*-chloro-*o*-cresol, drying the residual crystals, treating them with H₂SO₄ of 1.85 sp. gr. for about 4 hrs. at about 100° to sulfonate the *p*-chloro-*o*-cresol, dissolving in at least 100 kg. of H₂O and driving off the unaffected dichlorocresol with steam, heating to dryness whereby the sulfonic acid is decomposed, and finally melting the crystals with steam and running off the first liquid, which may possibly contain a little *o*-chloro-*o*-cresol. Cf. *C. A.* 9, 531.

28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

The quantitative determination of sugar by reduction of copper solutions. R. VAN MELCKEBEKE. *Chem. Weekblad* 12, 823–6(1915).—A loss of wt. of Cu₂O occurs in the detn. of sugar by the reduction method, due to the reduction of Cu₂O by the C of the burning filter. Oxidation with HNO₃ does not wholly correct this loss as Cu disappears with the acid fumes. M. therefore recommends the following procedure: Ppt. Cu₂O in the usual way, collect on a filter and wash; place the funnel over a Pt dish, dissolve the Cu₂O with a few drops of HNO₃ and carefully wash with hot water into the dish. Evap. the soln. of Cu(NO₃)₂ on the water bath, dry and convert into CuO by heating to redness. A loss of more than 1 mg. was not found after heating for 30 min. over a blast flame. Cu soln. according to Scheller gives better results than Fehling soln., as the absorption of copper by the filter paper in the latter method is very

annoying. An ash-free filter of 12 cm. diam. through which 50 cc. of Fehling soln. were filtered was washed with 500 cc. of cold H_2O . After ignition 3 mg. ash remained. A similar test with Scheller's soln. gave 0.5 mg. ash. J. T. FLOHIL.

Extension of the sugar-reduction table. N. SCHOORL. *Chem. Weekblad* 12, 481-2(1915); cf. C. A. 7, 282.—An addition to Schoorl's iodometric method for the detn. of reducing sugars. A table is given for arabinose, xylose, galactose, mannose and rhamnose. J. T. FLOHIL.

Experiments on the determination of sucrose by single and double polarization in the chemical control of white sugar manufacture by the Battelle process. H. S. WALKER. *Intern. Sugar J.* 17, 467-71(1915); cf. C. A. 9, 975.—(1) Solns. of pure sucrose may be boiled with lime with no appreciable loss. (2) Solns. of invert sugar when heated with lime yield decompn. products whose lime salts in neutral or faintly acid soln. have a weak negative rotation, but on treatment with strong acids (as in Clerget method) assume a strong positive rotation. (3) Adding these decompn. products to a soln. of sucrose causes a slight apparent loss in direct polarization, and a marked loss in sucrose by Clerget. (4) In case invert sugar has been decompd. by lime in the presence of sucrose, the apparent loss of sucrose, both by direct and Clerget, is greater than when the invert sugar is decompd. alone and then added to the sucrose soln., the loss by Clerget being much more pronounced than by direct polarization. (5) As great or greater apparent losses of sucrose occur when invert sugar with or without sucrose is allowed to stand a sufficient time with lime in the cold as when heated, the loss, however, being greater when decompn. occurs in the presence of sucrose. (6) Clerget process is inapplicable to cane juices which have been boiled with lime, owing to glucose decompn. products giving too low results. (7) The Clerget process applied to pure sucrose solns. of the concn. of cane juice gives results higher than the direct polarization by about 0.3% of the total sucrose present. This should be allowed for in comparing the direct polarization of juices whose glucose has been destroyed by lime with Clerget detns. on the original juice. A. GROSS.

The handling of cane damaged by frost. WM. E. CROSS. *Revista industrial y agricola de Tucuman; Sugar* 17, No. 10, 34-6(1915).—The damaged cane should be ground as soon as possible after removal from the windrow as atm. conditions cause rapid deterioration. The raw juice should be clarified immediately after extrn. and great care should be exercised in keeping the mill and tanks scrupulously clean in order to avoid infection. High acidity of the juice is partially neutralized with Na_2CO_3 and the juice then clarified with S fumes and CaO as usual. The Na_2CO_3 forms salts which are less meclassigenic and troublesome than the Ca salts. The boiling of the juice will depend upon the extent to which the cane was damaged. If the juice takes on a foamy appearance and refuses to boil, it is too badly fermented to be workable at a profit, and steps should be taken to have the cane cut lower thereafter, to prevent a recurrence of the trouble. A considerable quantity of molasses of comparatively high purity is obtained and if it is left standing for a long period in crystallizers or tanks, a fairly large yield of sugar can often be obtained therefrom. The presence of the gum dextran produced by fermentation (but rarely met with in the frozen cane of Louisiana) may cause serious errors in the detn. of the sucrose due to its high positive rotatory power. A method given is to weigh out the normal wt. of the juice for the analysis, clarify with Pb subacetate and make up to a vol. of 100 cc. with 60% EtOH (or greater strength if much gum is present). The soln. is filtered and polarized as usual. The acidity of the juice is detd. with 0.1 N NaOH using phenolphthalein as indicator. The number of cc. of NaOH required to neutralize 10 cc. of the juice is termed the "acidity" of the juice. A. GROSS.

Practical points in drying sugar beets. H. CLAASSEN. *Deut. Zuckerind.* 40, 383(1915); through *Wochschr. Zentralver. Rübensuckerind.* 53, 342.—The stirrers wear faster than when drying pulp, and must be made heavier. Instead of the regular chips, smooth flat slices should be made to prevent excessive loss of juice and burning of the finest material. The furnaces should be allowed much excess air so that the CO_2 in the flue gas is not over 5%; the temp. of the gases leaving the furnace should be not over 800° . They may be cooled to $100\text{--}120^\circ$ before leaving the drier. The dried slices must be cooled to $60\text{--}80^\circ$ and be dried to less than 10% H_2O ; otherwise they pack and heat, and may even completely carbonize. There is a loss of from 1.0 to 1.5° in polarization and 0.3–0.8% in dry substance, the latter perhaps more apparent than real. In normal times it would not pay to dry beets directly, unless toward the end of a campaign when the beets became rotten or frozen and are therefore difficult to work up for sugar. Such beets when dried make satisfactory fodder.

W. L. BADGER.

Determination of the yield in drying sugar beets, and the behavior of marc on drying. A. HERZFELD AND O. SCHREFFELD. *Z. Ver. Zuckerind.* 65, 311–20(1915).—A sample of dried beet flour gave 11.27% marc, from which the marc of the fresh beets was calcd. as 2.96%, a figure much lower than ordinary. If the beets had 4% marc, the marc in the flour should have been 15.2%. Errors in the marc detn. are of 3 kinds: (1) Pectins easily pass into colloidal soln. and run through the filter. (2) It is possible that during the ripening period the pectins become more or less hydrated and consequently lose wt. on drying at high temps. (3) On heating with H_2O parapectic acid is formed, and this is a strong enough acid to invert sucrose and partly or entirely to destroy the invert in the course of such a process as drying beet chips. Marc was detd. in fresh beet pulp in the usual way (drying to const. wt. *in vacuo* at 108°), and also in the same pulp after it had been dried at various temps. Pulp dried in air at 100° gave 20–30% less marc than the same pulp when fresh. This was due to the fact that some marc was rendered sol. by heating and not to thermal decompn. with loss of wt., since samples of pure marc obtained from fresh pulp only began to decompose with loss of wt. when heated 15 hrs. at 160° . Samples of marc obtained in the usual way, when subjected to a repetition of the original detn. lost about 13%. That is, marc is rendered partially sol. by drying in a vacuum at 108° . Marc dried in air at 140° lost 20% when subjected to a redetn. Marc heated *in vacuo* at 108° with an equal wt. of pure dry sugar lost 0.5% on drying and 20% on a redetn.; heated with sugar in air to 120° for 70 hrs. marc showed some decompn. (brown color) and a loss of 10% on a redetn.; while when it was heated to 140° with sugar there was considerable charring and more marc was found on redetn. than had been taken. High temps. evidently cause a reaction between marc and sugar forming easily decompd. substances. It would seem that in view of the sensitiveness of marc to comparatively mild treatment, it would be desirable to have very exact directions laid down for the marc detn.

W. L. BADGER.

Report of progress in sugar beet trials. J. W. INCE. N. Dakota Agr. Expt. Sta. *Bull.* 113, 251–69(1915).—This bull. reports results of analyses and gives information regarding the cultural treatment and climatic conditions under which 106 samples of sugar beets were grown.

R. C. ROARK.

The use of dried beets for sugar extraction. H. CLAASSEN. *Centr. Zuckerind.* 23, 1002(1915); *Wochschr. Zentralver. Rübensuckerind.* 53, 468(1915).—Wiechmann has advocated this, but C. refers to the fact that there is always some loss of sugar on drying and on storing, that much marc previously insol. is readily sol. in H_2O after drying, and that invert is present in the dried material. Assuming the most favorable

conditions for drying, no advantage can be found for this process when costs are considered.

W. L. BADGER.

Innovations in dry liming. H. EBERHARDT. *Deut. Zuckerind.* 40, 10(1915); through *Wochschr. Zentraber. Rübensuckerind.* 53, 69.—The CaO descends slowly in a thin layer down a spiral while the juice is rapidly pumped in the opposite direction. The time of contact is 18 min. Flakes of CaO are carried up by the juice and quickly dissolved; insol. material falls to the bottom and is removed by a screw conveyor. A CaO weigher may be dispensed with, and the outlet valve set to allow the juice to escape with any desired alkalinity.

W. L. BADGER.

Continuous saturation. FR. RASMUS. *Deut. Zuckerind.* 40, 265(1915); through *Wochschr. Zentraber. Rübensuckerind.* 53, 263.—An upright closed cylinder, 2.4 m. diam. by 4 m. high, has inside it another concentric fixed cylinder and hanging between the two a movable cylinder. Juice enters at the top and flows down between the outer and movable cylinders, up between the movable and inner, and out the center. Coils are arranged in the annular spaces to direct the CO₂ against the moving liquid. The movable cylinder rotates and to both it and the fixed cylinders are fastened flat stirring arms. There is no deposit in the app. even if it is stopped. A definite alkalinity can be maintained with great ease, and the utilization of the CO₂ is unusually high.

W. L. BADGER.

The latest prescribed rules for chemical control in the cane sugar factories in Java. H. C. PRINSEN GEERLIGS. *Louisiana Planter* 54, 269-70, 284-5(1915); cf. *C. A.* 9, 2990.—Methods are given for the sampling and analysis of bagasse, raw, mill, residual and clarified juices, filter press mud and sirup.

A. GROSS.

A study in the chemical control of cane sugar factories. IV. NOEL DEER. *Intern. Sugar J.* 17, 460-2(1915); cf. *C. A.* 9, 3374.—A control formula for available sugar is given as $100 s(j - m)/j(s - m)$, where s , j , and m represent the purities of raw sugar, sirup and molasses, resp., and are distinguished by the suffixes a , g , and r , to denote whether reference is made to the absolute, the gravity or the refractive standards. This formula is applicable to detns. of sugar only and can not be used with polarizations. In applying this formula it is essential that all purities and quantities of sugar be referred to sugar % and not to polarization; all purities must be referred to the same standard of reference, when gravity and refractive standards are used all detns. of solids must be made in the appropriate concn.; sugar lost in press-cake and mechanically is regarded as available in the proportion indicated in the formula; no attempt is made to fix arbitrarily a value for the purity of waste molasses. The formula is intended to be used with the purity actually observed in each factory. By "available sugar" is meant that proportion of the sugar originally present in a sirup of purity j , which must be removed at a purity s , to leave a residue of purity m . D. notes as erroneous the impression prevalent in many cane sugar laboratories, that the difference between Brix and total solids and also between polarization and sugar % is not great in juices and raw sugars and that no great error is introduced if the 2 former detns. be used, but that with molasses total solids and sugar % must be used. This reasoning is considered faulty because the seemingly small differences in juices and sugars refer to a very large wt. of material, the apparently large differences in molasses being referred to a much smaller wt. of material, and also because the basis of reference is made in one instance to Brix or grav. solids, and in the other to total solids or abs. solids. Owing to this confusion of ideas, D. has frequently accused many factories of obtaining more sugar than the analyses showed possible.

A. GROSS.

Simple device for sampling juices from the first carbonation. ZSCHEYE. *Deut. Zuckerind.* 39, 1044(1914); 40, 12, 63(1915); through *Wochschr. Zentraber. Rübensuckerind.* 53, 69.—About 1.15-1.20 m. above the juice level in the carbonation tank,

an angle cock and funnel are attached, the funnel about 25 cm. high and 20 cm. in diameter. When the CO_2 is turned on, if the cock is opened, foamy juice blows into the funnel. The funnel is about $\frac{1}{2}$ filled and then at intervals the cock is quickly opened and closed so that the level of juice in the funnel rises a few cm. each time. When the juice no longer rises on opening the cock it has an alkalinity of 0.07-0.08 and the carbonation is finished. If CO_2 is passed longer the juice level in the funnel will fall on opening the cock and the alkalinity will be found below 0.07. During the test any device for beating down foam must be stopped. In Z.'s factory, this test has made it possible to employ any unskilled labor on the carbonation station. *Discussion.* CLAASSEN, BANDO. C. does not believe that a uniform alkalinity can be carried when only the height of the foam is tested. He warns against supplanting control with phenolphthalein by such an empirical method. Z.'s method cannot be used at all with continuous carbonation, which, C. thinks, is to replace carbonation in sep. pans. B., who has used a system similar to Z.'s for some years, said the continual opening of the cock may cause the funnel to run over. So B. substitutes an observation window, 30 X 8 cm., at the foam level. As soon as the alkalinity reaches 0.07 the level of the foam can be plainly seen to fall at once. If satn. takes longer than usual the glass shows the reason at once. If too much CaO has been added, the motion of the foam is unchanged; if the gas line is stopped or the pump slow, the motion of the foam is less violent than usual. The glass must be so mounted as to be easily changed, for it needs cleaning every 2 days.

W. L. BADGER.

Systems for dealing with condensation from heating and evaporating plant. E. W. KERR. *Louisiana Bull.* 149; *Intern. Sugar J.* 17, 474-6(1915); see C. A. 9, 869.

A. GROSS.

Corrosion of iron parts in the return of diffusion waters to the battery. SCHIRMER, EGGELING, ZSCHEYE. *Deut. Zuckerind.* 40, 9(1915); through *Wochschr. Zentralver. Rübensuckerind.* 53, 68.—S. found that most Fe parts subjected to the action of the returned H_2O scarcely lasted one campaign. Neutralizing the H_2O with $\text{Ca}(\text{OH})_2$ caused such difficulties in filtering and boiling that it had to be abandoned. E. found that sand was not responsible for the corrosion, and adopted the following method: mash with fresh water, press with returned water, and lead the waste waters over a cooling surface where CaO is added (enough surface is provided so that no CaO returns to the plant). No Fe parts have corroded through since this was adopted. Z. adds the condensed water to the returned battery water, thus reducing the acidity by the NH_3 . Keeping the returned water as cool as possible helps. Brass or bronze should replace Fe wherever possible.

W. L. BADGER.

Pulp catchers. GEHRKE, ZSCHEYE. *Deut. Zuckerind.* 40, 9(1915); through *Wochschr. Zentralver. Rübensuckerind.* 53, 68(1915).—G. uses the Joerning and Sauter pulp catcher for returning water to the battery. H_2O from the pulp-sump passed a conical pressed brass screen with $\frac{3}{4}$ mm. slots, and then passed to the pulp catcher where daily 130 cwt. of 9% dry substance were recovered. The sieve of the catcher needed frequent renewals, but this was done during Sunday stoppages and the screen cost little. Z. used a 2 mm. screen instead of the $\frac{3}{4}$ mm., and had equally good results in the pulp catchers. In returning diffusion water, the greatest difficulty is caused by the material which passes the pulp catcher. It consists of sand or earth with little org. substance, but there seems to be no way of removing it. Z. finds any type of pulp catcher on the market suitable for the return of waste waters.

W. L. BADGER.

Vacuum apparatus for sugar factories. II. E. W. KERR. *Louisiana Planter* 54, 217-21(1915); cf. C. A. 8, 2502, 2964, 3730; 9, 2721.—Several types of condensers are shown and described. Owing to the low thermal conductivity of H_2O , it is necessary to spray the water into as fine a condition as possible in order that its temp. may be

raised to that of the steam in the shortest possible time. The most satisfactory way is to convert the H_2O into spherical drops though it is not uncommon to break it up into sheets. An objection to the overflowing of H_2O in sheets of varying thickness is that the curtains of H_2O thus formed may result in an appreciable resistance to the flow of vapors from one end of the condenser to another. The author has found a difference of as much as $1\frac{1}{2}$ in. of Hg between the two ends of the condenser. The rate of evapn. and the amt. of vapors given off from vac. pans depends upon several factors such as the quantity of heating surface, whether coil or calandria, the steam pressure, the vac. the cleanness of the heating surface, the product being boiled whether firsts, seconds or thirds and the av. time the heating surface is on. In tests made by the author, an evapn. of 18 lbs. per sq. ft. of heating surface per hr. was obtained. The amt. of vapor a condenser of given dimensions will condense and the vac. it will maintain are functions also of the air pump capacity. If the latter is not sufficient, the vac. will be low no matter how well the condenser itself is designed. The finer the water is sprayed in the condenser, the smaller also the condenser will have to be. A graphical log of a coil vac. pan test shows that the rate of H_2O evapn. is consistent. A. G.

Changes of the starch in potatoes during drying. H. I. WATERMAN. *Chem. Weekblad* 11, 332-7 (1914).—Drying at $40-50^\circ$ causes a greater change of starch into sugar than drying at 60° and higher. The content of H_2O -sol. carbohydrates was detd. after cold water extn. by polarization before and after inversion, followed by a detn. of the reduction power with Fehling soln. When the potatoes were dried at $40-45^\circ$, 14.8% starch and 2.25% sucrose were found; when they were dried at 60° , 18.3% starch and 1% sucrose. The N content was the same in both cases. Reduction and polarization proved that almost all of the sugar consisted of sucrose. Sucrose crystals were obtained from an alc. ext. Potatoes were ground and made into a pulp with iced H_2O . The liquid was filtered and the sugar detd. No glucose nor invert sugar was found; sucrose was 0.4%. The potatoes were then dried at 35° , 45° , 55° and 105° and yielded, resp., 3.3%, 2.1%, 1.6% and 0.4% of sucrose, only very small amts. of other sugars being present. The fact that during the drying at 105° no increase of sugar had taken place is attributed to the suspension of the enzymic action at this temp. J. T. FLOHL.

Starch, and its employment in industry. RUDOLF MATTHIAS. *Grimma. Chem. App.* 2, 223-6, 233-5, 245-7 (1915).—Descriptions, with 13 cuts, of app. for making starch from potatoes and corn and its conversion into sirup, dextrin and glucose. Dimensions of app. for making 11 tons of glucose per 24 hrs., and general directions for operating, are given. J. H. MOORE.

Dextrin; glucose. F. E. RUDMAN. *Brit.*, 16,562, July 9, 1914. Starch, farina, or the like is converted into dextrin, or, by longer treatment into glucose, by first mixing the starch with an acid or the like by delivering the powder in a spray or shower into a container, into which the acid or the like is sprayed, and simultaneously or subsequently heating the mixt.

Evaporating sugar saps. F. HALLSTRÖM and O. F. BRANDT. *Ger.*, 281,720, June 4, 1913. Addition to 265,676 (*C. A.* 8, 1884). An app. is specified for evapg. sugar saps and other liquids which suffer from protracted overheating.

30. RUBBER AND ALLIED SUBSTANCES.

R. T. STOKES.

Permanence of rubber goods in storage. DROSTE. *Pharm. Zig.* 60, 328-30 (1913).—As the result of numerous expts. to det. the durability of rubber products

in storage, the following conclusions were drawn: (1) Higher temps. not exceeding 32° apparently exercise no deleterious influence. (2) Low temps. to -8 to -10° harden the gum but do not necessarily produce permanent injury. (3) So far as external influences are concerned, all samples showed similar behavior, deterioration manifesting itself in the same way and at the same rate. (4) Moisture affects tubing neither favorably or otherwise. In cases where samples had free access to air, especially at elevated temps., a yellowish gray color gradually developed, the material becoming coated with fungi. (5) Tubing deteriorated in direct sunlight even when coated with paraffin and with exclusion of air. In the presence of moisture, the samples became sticky. (6) In diffused sunlight, tubing became fissured and brittle at the end of 2 yrs. and 9.5 mos. (7) Other samples remained unimpaired in the course of 3.5 yrs. exposure to air but with exclusion of light. The expts. show further that rubber products in general are unfavorably influenced in storage; that, while the effects of air alone are very slight, light is harmful under all conditions, especially direct.

W. O. E.

Synthesis of caoutchouc. A. HEINEMANN. Brit., 15,572, June 29, 1914. MeOAc is employed instead of EtOAc in the process described in 18,506, 1912 (C. A. 8, 585).

Vulcanizing caoutchouc. BAYER & Co. Brit., 12,661, May 22, 1914. Natural or artificial caoutchouc or caoutchouc-like substances are vulcanized in the presence of such NH_3 derivs. of a basic reaction, other than those which liberate free NH_3 under the conditions of vulcanization, or such nitrogenous organic bases, other than piperidine or its homologs or derivs. of these bases, as possess a dissociation const. in aq. soln. greater than 10^{-8} . Examples of the bases which may be used are NaNH_2 , benzylamine, naphthylenediamine, quaternary NH_4 bases, the addition product of NH_3 and acetaldehyde, and *p*-phenylenediamine.

Rubber substitute. J. BAUER. Brit., 1,171, Jan. 15, 1914. The substitute is made by mixing comminuted animal tissue, such as sinews, after heating with an astringent soln. such as ZnCl_2 or HCl , with starchy matter, such as powdered tapioca. The dough thus formed, after being dried, is preferably mixed with a small proportion of rubber latex or a soln. of rubber or resin, *e. g.*, 6-12% of rubber dissolved in turpentine. The product is heated until it is tough, and may be applied as a dressing to leather, canvás, or other fibrous base.

Coagulating latex. DUNLOP RUBBER Co. and E. MOSINGER. Brit., 16,096, July 6, 1914. Latex is coagulated by the addition of a soln. of Al, Bi, or Zn chloride or mixts. of these. About 1 g. of 1 or more of these salts is dissolved in 10 cc. of H_2O , and the soln. is stirred into 100 cc. of latex.

Rubber tires. CONTINENTAL-CAOUTCHOUC- UND GUTTA-PERCHA-COMPAGNIE. Ger., 283,937, May 29, 1914. Press for their manuf.

Published by the American Chemical Society, Easton, Pa.

Entered as Second-class Matter at the Post-Office, Easton, Pa.

Communications for the Editor should be addressed to E. J. Crane, Ohio State University, Columbus, Ohio.

The Council have voted that no claims for copies lost in the mails can be allowed, unless such claim is received within "sixty days" of the date of issue, nor if due to failure to give sufficient notice of change of address. Charles L. Parsons, Secretary.

Remittances for annual membership dues or for subscriptions, changes of address, orders for subscriptions or back numbers, claims for missing numbers and all matters connected with the Proceedings should be sent to the Secretary, Charles L. Parsons, Box 505, Washington, D. C.

Secretary's Office: Box 505, Washington, D. C.
Eschenbach Printing Company, Easton, Pa.

The American Chemical Society

The Board of Directors of the American Chemical Society has fixed the following schedule of prices for its publications

Subscription Rates

Journal American Chemical Society	\$ 6.00
Chemical Abstracts	6.00
Jour. Industrial and Engineering Chemistry	6.00
Two Journals to same address	10.20
All three Journals to same address	12.60

Back Numbers and Volumes

	To Members	To Non-members
Single Numbers: J. A. C. S.; J. I. E. Chem. or Chem. Abs. .	0.50	0.60
Proceedings, Vol. 1 (1876); Vol. 2 (1877).....	2.00	2.50
J. Am. Chem. Soc., Vols. 1-16 inclusive, each....	4.00	5.00
J. Am. Chem. Soc., Vols. 17-37 inclusive, each....	5.00	6.00
Chem. Abs., Vol. 1, 2, 3 or 5 complete, each.	10.00	12.00
Chem. Abs., Vol. 4, 6, 7, 8 or 9 complete, each....	5.00	6.00
Index to Vols. 1-20, J. Am. Chem. Soc.....	0.50	0.75
Index to Chem. Abstracts, Vol. 1, 2, 3, 4, 5, 6 or 7.....	1.00	1.00
Jour. Ind. and Eng. Chem., Vols. 1-7.....	5.00	6.00
Foreign Postage, each Journal 75c.; Chemical Abstracts, \$1.00 a year.		

Special Discounts to Newsdealers, Libraries and Institutions of Learning

Complete sets, Vols. 1 to 35, of the Journal; Proceedings, Vols. 1 and 2, and Vols. 1 to 7 of Chemical Abstracts may be had of the Secretary.

The following numbers can be furnished only in complete sets, viz: J. Am. Chem. Soc., 17 (1895), 1 and 8; 18, 5; 19, 1; 20, 3; 22, 3.

Besides the above, the following numbers can be furnished only in complete volumes, viz: J. Am. Chem. Soc., 26, 4; 29 (1907), 4; 30 (1908), 2, 3, 4, 5, 6 and 7; 33, 3, 4 and 9; 34, 9, 10 and 11; Chemical Abstracts, 1 (1907), 3, 12, 13, 14, 15 and 16; 2 (1908), 1 and 2; 5, no numbers except 1, 4 and 6; Jour. Ind. and Eng. Chem., 1, only No. 11; 3, Nos. 3 and 12; 4, Nos. 3, 4, 5, 7 and 10; 5, No. 1.

Advance payment is required and should be made by check or money order only. Stamps not wanted.

The Council has voted that the Secretary shall honor claims for non-receipt of publications only if made within sixty days of their issue. Claimants must also directly state that the publication was not delivered at their recorded address. "Missing from files" is no proof of non-receipt.

The Society will not be responsible for loss due to change of address unless notification is received one week in advance of issue.

Members or subscribers desiring their Journals or Abstracts forwarded from an old address should always notify their Postmaster and leave necessary postage.

The names of members and subscribers, whose Journals or Chemical Abstracts cannot be delivered by the Post Office Department, will be cut off the mailing list at once, and will not be restored until correct addresses have been furnished.

In the absence of other information, the notices of change of address received from the Post Office Department will be considered as correct, and the mailing list changed accordingly.

All communications should be addressed to

CHARLES L. PARSONS, Secretary,

Box 505, Washington, D. C.

PATENTS

Abstracts of patents are included under the appropriate divisions of the journal: those on organic compounds, unless they pertain especially to some other division, are under Pharmaceutical Chemistry. The abstracts of U. S. patents are prepared by Earl T. Ragan, those of Canadian patents by Russell S. Smart, of Fetherstonhaugh & Smart, Ottawa (50 Queen St.), and all others by O. D. Swett. Most German patents are prepared, with permission, from the abstracts in *Chemiker-Zeitung* and Italian patents from those in *Annali di chimica applicata*. All other patents are obtained direct from the specifications.

Copies of any patent may be obtained for: United States, 5 cents, sent to the Patent Office, Washington, D. C.; French, one franc, sent to L'Imprimerie Nationale, 37 rue de Vieille du Temple, Paris; German, one mark, sent to the Patent Office, Berlin; British, eight pence, sent to Patent Office, London (extra postage outside United Kingdom); Austrian, write to the Patent Office, Vienna; Danish, write to the Patent Office, Copenhagen; Norwegian, 1 crown, Patent Office, Christiania; Swedish, 1 crown, Patent Office, Stockholm. Of Canadian patents, manuscript copies only are obtainable. They may be secured from Fetherstonhaugh & Smart, or the Commissioner of Patents direct. Estimates of cost may be obtained in advance.

In ordering a copy of a patent, the number of the patent, name of the patentee, and subject of the invention should be stated.

CHEMICAL ABSTRACTS

Vol. 10.

JANUARY 20, 1916.

No. 2

I. APPARATUS.

L. C. JONES.

An electrically heated pressure apparatus for the investigation of fusion and transition phenomena of salts, salt mixtures, metals and alloys. ERNST JÄNECKE. *Z. physik. Chem.* 90, 257-64(1915); cf. *C. A.* 10, 143.—An electrically heated pressure app. is described, by means of which fusion and transition points may be detd. from the relation between pressure and temp. Four diagrams and photographs of the app. are given in the text. The pressure, up to 20,000 kg. upon the piston, is not the universal pressure, and, therefore, the pressure-temp. points of the condition diagram cannot be detd. directly. As the friction in the pressure app. is often increased to a large extent by the flowing of the compressed substance, the pressure loss of the press is of importance.

H. JERMAIN CREIGHTON.

Simple gas burner for small laboratory furnaces. D. A. RANDALL. Baker Univ., Baldwin City, Kansas. *J. Ind. Eng. Chem.* 7, 873(1915).—The burner is made from standard pipe fittings. A 12 in. length of 2 in. pipe has a cap, drilled with as many $\frac{1}{8}$ in. holes as possible, screwed on one end. On the other end is a $2 \times 2 \times \frac{3}{4}$ in. tee. Low pressure air, $\frac{1}{2}$ in. water, is admitted through the 2 in. opening of the tee. Into the $\frac{3}{4}$ in. side opening is screwed a $\frac{3}{4} \times \frac{1}{4}$ in. reducing bushing which has been tapped out large enough to screw a $\frac{1}{4}$ in. pipe clear through. A $\frac{1}{4}$ in. ell on the end of this pipe faces toward the drilled cap and admits the gas. The burner gives a very steady flame and temp. high enough for assay work.

F. A. HARVEY.

Two burners for the demonstration and study of flame spectra. P. E. BROWNING. Yale Univ. *Am. J. Sci.* 40, 507-8(1915).—A salt-mouth bottle is fitted with a 3-hole stopper. Gas flows in by a glass tube in 1 hole; the second hole is fitted with a glass tube drawn out to a tip, over which a porcelain tube is supported, leaving a space between the stopper and tube for air to enter and mix with the gas as in a Bunsen burner. A thistle tube extends through the third hole with its lower end dipping into a soln. containing the salt whose spectrum is desired and a mineral carbonate. When a little HCl is added through the thistle tube the CO_2 evolved carries with it enough of the soln. to color the flame. The second burner differs from the first only in that the gas evolved is H. The soln. is acidified and a Zn tube fastened to a glass rod extending through the stopper so that the Zn may be raised or lowered. The colored flame obtained from either burner persists as long as gas is evolved.

F. A. HARVEY.

Extraction apparatus. A. A. BESSON. Basel. *Chem. Ztg.* 39, 860(1915).—A small wide-neck flask with a constriction at the base of the neck on which the thimble rests. A modified Storch cooler is in the short neck above the thimble, the app. being small enough to weigh on analytical balances.

J. H. MOORE.

A new apparatus for fat extraction. I. SELECTER. La. Agr. Expt. Sta., Baton Rouge, La. *J. Ind. Eng. Chem.* 7, 871-2(1915).—The app. is made in 3 parts, reservoir below, extn. section in the middle and condensing section above; each is fitted into the next by a ground glass joint. The reservoir is a 75 cc. Erlenmeyer flask. The extn. section is a straight glass tube 5 in. by 1 in. in which the ordinary Schleicher and Schüll⁶

capsule, with weighed sample, is placed. The condensing section consists of an 18×1.5 in. outer glass tube with upper flanged end and a waist, just above the ground glass joint to the extn. section, which supports a Soxhlet extn. tube with syphon outlet. Above the Soxhlet tube and hanging from the upper end of the outer tube by means of a flange is a tube, 12×1 in., with 2-hole stopper and inlet and outlet tube for the cooling water. This tube is drawn out to a point so that the condensed ether or other solvent drips into the Soxhlet tube, which thus fills up and periodically empties through the syphon flooding the sample tube. Results are given showing that the new app. gives greater uniformity than straight extn. or the Soxhlet method. It is also more rapid. The recovery of the solvent is easy and rapid and the cost of the app. small.

F. A. HARVEY.

Portable titrating table. R. E. OZIAS. U. S. Customs Service, N. Y. *J. Ind. Eng. Chem.* 7, 872-3(1915).—Standard soln. bottles of 2500 cc. capacity are let down into a table top and rest on a shelf 5 in. underneath. These bottles are connected with Squibbs automatic burets and a piping system whereby air under pressure from a Good-year air bottle can be used to force the solns. into the burets. A relief valve opened when the buret is full fixes the soln. at the proper level. White tiling is placed under the buret tips.

F. A. HARVEY.

A new test-tube stand. K. HOFMANN. *Z. angew. Chem.* 28, I, 368(1915).—This test-tube stand is intended particularly for use in lectures as the liquids in the tubes may be seen from top to bottom. The bottom of the stand is slightly raised in front, and attached vertically to this bottom is a back containing six half-round grooves in which the test tubes rest. This stand is supplied in porcelain with black, white or black and white backs, the selection of which depends upon the color of liquids to be shown in test tubes.

H. R. GUNDLACH.

A simple apparatus for filtration under diminished pressure. JAMES C. IRVINE. Univ. St. Andrews, Scotland. *Biochem. J.* 9, 321-2(1915).—The app. consists of a cylindrical tube with a delivery stop-cock at the lower end, the upper part being expanded into a bulb. A side-limb carries a three-way stop-cock, and connects with the pump. The filter funnel (or Gooch) is attached to this filter tube. This modification is particularly recommended for the sepn. of small quantities of cryst. matter from sirupy solutions.

B. HOROWITZ.

A sterile siphon tip protector. I. C. HALL. *Science* 42, 700(1915).—A bell-shaped cap is made by cutting the bulb of a 50 cc. pipet in the middle, leaving attached to each bell a tube 5-7 cm. long for union with the siphon tube, and drawing into this tube by means of a rubber tube, another glass tube of such size that when the rubber tube is released its elasticity binds the two together. The covered end of the smaller tube is then adjusted even with that of the bell tube and the rubber tube cut off, or used to connect to the siphon of the bottle. To prevent the lodgment of upwardly floating particles of lint upon the drop of liquid at the point, a test tube about 2.5×15 cm., with lip removed, is fitted by means of thin rubber, either inside or outside the bell. During use the protector may be protected by fastening it to another test tube. In certain cases a few drops of HCHO may be used in the protector.

F. W. S.

The sublimator and its use. F. F. EXNER. *J. Assoc. Official Agr. Chem.* 1, 208-9(1915).—The substance to be sublimed is weighed out into a 10 oz. Erlenmeyer flask, which is supported on a wire gauze, with asbestos, and heated gently with a small Bunsen flame. Condensation takes place on a closely coiled glass tube extending down through a cork into the flask. The lower end of the cork is protected by a layer of tin foil. An expansion tube with a cotton plug in its upper end extends through a 3rd hole in the cork. To use the app. the glass coil is dried and weighed, then put in

place in the flask. A slow current of water is passed through the coil and the caffeine or other substance slowly sublimed. It condenses on the cooled tube. After condensation is complete and the app. cool the tube is removed, a current of alcohol, then ether, then dry air, is passed through and it is dried in a desiccator and weighed. It is also necessary to weigh the expansion tube as there is usually 0.6 to 1.5 mg. in this tube.

F. A. HARVEY.

Electrically operated gas valve. ZENO OSTENBERG. San Francisco. *J. Ind. Eng. Chem.* 7, 872(1915).—O. describes a valve which has been in successful operation for a year and a half.

F. A. HARVEY.

A thermostat for moderate and high temperatures. J. L. HAUGHTON AND D. HANSON. *Engineering* 100, 378(1915); see *C. A.* 9, 3145.

E. H.

The measurement of high temperatures in practice. H. WILDA. *Feuerungstechnik* 3, 233-6, 247-9(1915).—The different types of pyrometers for industrial purposes are considered, methods for their use for special purposes being given together with the measures necessary for accurate results. The types considered are thermoelectric, resistance, optical, calorimetric and melting (Seeger cones, etc.).

H. R. G.

A new direct-reading viscosimeter. R. F. MACMICHAEL. Seattle, Wash. *J. Ind. Eng. Chem.* 7, 961-3(1915).—The fluid to be tested is held in a cup which can be rotated by means of a small d. c. or a. c. motor; the speed control is of the phonograph type. A small elec. heating coil brings the fluid to the desired temp. in place, after which the level is adjusted to a definite mark. A disk is suspended in the fluid by means of a torsion wire. The angle through which the torsion head must be turned to bring the disk back to the zero position when the motor is running is measured. The graduations on the torsion head are such that practical units, abs. units, and sp. viscosity may be obtained at one reading. The calibration can be checked and motor speed adjusted by the use of standard solns. of sugar sirup. The accuracy of the instrument under ordinary working conditions is 0.5% and by extra precautions may be made greater. The time required for a reading is very short. Colloidal solns. such as glues, gums, starch solns., gelatin, also mixts. such as catsup, etc., may be tested successfully.

F. A. HARVEY.

A cylinder friction and lubrication testing apparatus. A. E. FLOWERS. *Proc. Am. Soc. Testing Materials* 15, II, 399-414(1915).—F. describes, with cuts, an app. which is capable of testing cylinder lubricants at various rates of feed under piston-ring pressures from 2 to 9 lbs. per sq. in. and at steam temps. up to 426.6°. The cylinder has an 8-in. bore, the stroke is 8 in., and the app. is run at speeds up to 300 r. p. m. The results of tests are plotted showing the actual readings as taken and the effects of steam pressure, steam temp., and cylinder-wall temp. with and without steam, on the friction coeff. for 2 different lubricants.

F. W. SMITHER.

Bardill sampling machine. J. O. BARDILL. *Eng. Mining J.* 100, 803-4(1915).—This machine was designed for sampling wet and sticky mill concentrates and similar materials. The principal elements are a turret and its wormgear drive, incased in an oil-tight housing. A cutter arm is pivotally mounted on the turret and revolves in unison with it, except through about 40° in each revolution, when it is held stationary by a vertical detent bolt. The relative motion between the turret and the cutter arm effected during this 40° period of inactivity of the cutter arm produces tension in a coil spring, which is exerted between the turret and pivoted cutter arm. A cam underneath the rim of the turret releases the detent bolt at the proper time, causing the cutter to pass rapidly through the stream owing to the spring action independently of the motion of the turret. The action of the cutter arm is extremely rapid, and it is suddenly stopped by its opposite end coming in contact with a rubber

buffer post. This clears the cutter of any material that might adhere. The material is deposited in a receiving box properly placed. The power required is so slight that the turret may be operated through its entire revolution, and against the spring action, by turning the wormshaft by hand. The machine may easily be made into a self-contained, portable affair by mounting a small driving motor on the base plate.

F. W. SMITHER.

Heat losses of various electrically heated laboratory boilers. AD. RITTERS-HAUSSEN. *Elektrotechn. Z.* 36, 300-2 (1915).—An illus. description of several types of boilers, elec. heated. Cooling curves for each type are shown. It was found that the most efficient boiler had its heating unit centrally located near the bottom and completely submerged in the H_2O ; the feed cock is kept open and the outlet cock is closed. By direct calorimetric detn. an efficiency of 94% was obtained with this type (see fig.); a boiler with the unit laterally placed showed 82% efficiency, and one with the unit under the bottom of the boiler 66%. A 200-l. boiler with an efficiency of 94% is cheaper in Germany than a gas-heated boiler when the cost of electricity is 5 pfennig (1.25 c.) or less per kw.-hr.

C. G. FINK.

"Imperial" vacuum pump. ANON. *Power* 42, 711 (1915).—A sectional view of this pump is given. It is designed for condensing and other service where a high degree of vacuum is desired. Corliss-type intake valves are so placed in the cylinder head that the clearance is exceptionally low. The action of the valve is positive and quick, and, being independent of the intake pressures, the pressures within and without the cylinders are as nearly equal as possible. The intake ports are large and direct, which, together with the water-jacketing of the valve, tends to cool the intake gases. Lubrication is by the bath system. A duplex construction is also described.

W. E. RUDER.

Liquid measuring devices. H. WINKELMANN. *Z. angew. Chem.* 28, I, 363-4 (1915).—The device described measures liquids by weight, and is used for the measurement of large quantities. The liquid scale depends on the principle of automatic weighing with the help of two tilting vessels, which can be alternately filled or emptied by means of an automatically working dividing scale. The accuracy attained is $\pm 1.0\%$ but with additional devices an accuracy of $\pm 0.1\%$ may be obtained. The app., with the exception of the knife edges on which the tilting vessels rest, has no parts subject to wear that would influence the accuracy of measurement, which are common to most other liquid measuring devices.

H. R. GUNDLACH.

Drying chambers and ovens of modern construction heated directly with steam or gas. H. WINKELMANN. *Chem. App.* 2, 257-9 (1915).—A general discussion, without cuts, of the principles on which such app. should be constructed. J. H. M.

Apparatus for the determination of phytosterol (WAGNER) 12. An electroplating barrel 4.

Gas-analyzing apparatus. U. S., 1,157,866, Oct. 26. J. W. HAYS and C. W. HAYS. A gas-analyzing app. of the type shown in U. S. pat. 1,153,912 (*C. A.* 9, 2998) is enclosed in a bath of H_2O which is maintained at const. temp. while the app. is in use and thus uniform temp. of the gas is secured during measurement and absorption.

Siphon pump for handling acids or other corrosive liquids. A. FERRARIS. U. S., 1,159,201, Nov. 2. Cf. *C. A.* 9, 2010.

Acetylene generators. R. BERCHEN. U. S., 1,159,159, Nov. 2.

Acetylene generator. J. M. HOOVER. U. S., 1,161,675, Nov. 23.

Acetylene generator. L. WAGSCHAL. U. S., 1,159,814, Nov. 9.

Acetylene generator. A. D. LONG and L. D. HARPER. U. S., 1,159,968, Nov. 9.

Acetylene generator. F. F. NOVAK. U. S., 1,162,708, Nov. 30.

Apparatus for generating and storing acetylene. O. K. STUART. U. S., 1,160,668, Nov. 16.

Oxygen generator. W. F. MUEHL. U. S., 1,160,524, Nov. 16. KClO_3 or a mixt. yielding O on heating is placed in the receptacle 48 and heated by an elec. resistance heater 51 to produce O, especially for immediate use while still warm in removing C from internal combustion engines.

Apparatus for effecting reactions with hydrogen under pressure. M. PIER. U. S., 1,159,865, Nov. 9. To prevent leakage of H, a layer of molten Wood's metal or other readily fusible alloy, D, is maintained between the inner wall B and the outer casing A (which may be of Fe or steel). The inner wall B may be of porcelain or metal. The app. will withstand 150 atms. pressure without leakage.

Apparatus for cooling, drying and electrically ozonizing air. J. STREYNIS. U. S., 1,162,415, Nov. 30.

Apparatus for making carbon-black by sooty gas flames. G. L. CABOT. U. S., 1,162,131, Nov. 30.

Apparatus for purifying used lubricating oils. F. E. CORWIN. U. S., 1,161,197, Nov. 23. The oils are strained and washed and metallic particles are removed magnetically.

Smelting ores or incinerating garbage. W. R. HESLEWOOD. U. S., 1,160,509, Nov. 16. Crude petroleum is used as fuel at the burners 8 and solid fuel also may be used in the furnace. Ore to be smelted or garbage, etc., to be incinerated is supplied from the hoppers 3 and H_2O circulated from the tank 16 through the nozzle 13 maintains a draft from the outlets 10 and pipe 11.

Rotary kilns. E. C. R. MARKS. Brit., 17,145, July 20, 1914. In a rotary kiln for treating ores, cement, etc., of the kind in which the burning and cooling zones are formed in the same rotating tube, means, *e. g.*, Fe ribs or projections, are provided in the cooling zone for facilitating the interchange of heat between the material and the cooling air. The fuel supply tube or nozzle, which extends over a considerable portion of the cooling zone, is formed of thin sheet metal and is supported at one end only.

Electric hygrometer. C. LÜBBEN. Ger., 284,867, Feb. 22, 1914. A member,

the elec. resistance of which is dependent upon the moisture, is brought into contact with the gas under examn. and introduced, as resistance, in an elec. circuit.

Electrically heated cathode for discharge tubes. SIEMENS & HALSKE, AKT.-GHS. Ger., 285,031, June 23, 1914.

Regulator for gas condensers and pumps. GEBR. MEER. Ger., 284,946, Mar. 19, 1912.

Glass atomizer for liquids. K. HENNICKE. Ger., 284,980, Sept. 15, 1914.

Tube stamping machine. MASCHINENFABRIK HOCHDORF, FREY & CIE. Ger., 284,991, May 6, 1913.

Surface condensing plant. F. L. RICHTER. Ger., 284,833, Mar. 19, 1912.

Heated container for molten material to be used in spraying apparatus. METALLATOM, G. M. B. H. Ger., 284,832, Mar. 19, 1914.

Apparatus for dressing fine ore and coal. F. JÜNGST. Ger., 284,536, Aug. 21, 1914. Addition to 283,921 (C. A. 9, 2473).

Crucible furnace. A. ERICHSEN. Ger., 284,914, Jan. 9, 1914.

2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS.

Assistants: E. B. MILLARD and A. B. CARTER.

Graphical representation of the relation between atomic weight and velocity of vibration of elementary atoms at their melting points and the natural system of elements in such graphs. P. P. VON VEIMARN. *J. Russ. Phys. Chem. Soc.* 47, 481-9 (1915).—This is a brief supplement to von V.'s work on contractive and expansive energies (C. A. 9, 2832), and in greater detail will be incorporated into the book he is prepg. on the subject. It is shown that instead of representing the periodic law, as is customary, by a curve on which atomic wts. (A) are plotted against abs. m. p. (T_s), it is better to use as coördinates A and T_s/A or still better A and $\sqrt{T_s/A}$. In the latter case the curve resembles the one given by Biltz (C. A. 5, 3745) but is much simpler and more clearly brings out certain regularities, B. having vitiated the simplicity of the graph by introducing the factor 2.12. All the conclusions drawn by B. follow in a simpler manner from von V.'s graph, and in addition to this the latter shows that the value of $\sqrt{T_s/A}$ (3.73) for H brings this element in near relation to those elements (P, As, Se) which under ordinary conditions appear in both the metallic and metalloid states. In the book will be given several other graphs of the periodic system.

H. M. GORDIN.

Valence and complex compounds. I and II. G. POVARNIN. *J. Russ. Phys. Chem. Soc.* 47, 217-62, 501-28, 989-1036 (1915).—Werner's theory of the constitution of complex compds. is criticized because (1) it necessitates the assumption of 2 kinds of valences, principal and supplemental, with a further differentiation of groups into ionogens and non-ionogens, thus making 3 varieties of affinity bonds; (2) it assumes a difference between atomic and mol. unions; (3) it assumes that while the number of principal valences of an element depends on the position of the latter in the periodic system, the number of its supplemental valences is in no way related with this system; (4) it makes it very difficult in many cases to predict the number of possible isomers, since the coördination number, not being dependent on the periodic system, cannot even approx. be fixed beforehand; (5) the theory explains only the structure of the inner sphere where atoms or groups are linked directly to the central atom, but fails to show how this sphere is united with the outer sphere where union with the central

atom is through the intermediacy of other atoms. To overcome these difficulties P. proposes an hypothesis consisting of the following postulates: (1) The atoms themselves are complex systems of positive and negative affinities in unequal amts., so that an element is positive when the positive charge exceeds the negative, and negative when the reverse is the case. While the value of the excess is not known, we may indicate the greater charge by 2 signs and the lesser by 1. An atom of H, *e. g.*, is represented as H^{++} , while that of Cl as Cl^{--} . (2) The valence of H is n where n is any whole number greater than 1, so that the max. valence of any element is n times the number of the group to which it belongs in the periodic system. Assuming $n = 2$ will suffice for the present. The formula of a mol. of H is therefore $(H^{++} ::::: + + H)$, and that of Cl $(Cl^{--} ::::: - - Cl)$, while that of HCl is supposed to be $(H^{++} ::::: - - Cl)$. As shown by these examples, in a mol. of H or Cl the satn. of opposite affinities takes place between pairs of unequal charges, while in HCl (and similar cases) the opposite charges satg. each other have the same value; in other words, in a mol. of H or Cl both affinity bonds have the same value, each consisting of 2 positive charges linked to 1 negative, but in HCl 1 bond consists of 2 positive charges satd. by 2 negative ones, while in the other bond 1 positive sats. 1 negative bond. Of these 2 bonds in HCl the 1st consisting of 2 pairs of opposite charges may be assumed to be more stable than the other consisting of single opposite charges. Hence when a dissociating agent acts on a mol. of H or Cl the dissociation will in most cases be complete, while the same agent acting on a mol. of HCl will more frequently cause halving of the bonds, removing the less stable bond only, and leaving intact the more stable one, thus giving the group $(H^{++} ::::: - - Cl)$, with liberation of free polar affinities capable of uniting with other atoms, or groups to form complexes. This explains the formation of complexes between mols. (3) The bonds between atoms have the power to oscillate, always tending to form such compds. as are most stable under the given conditions. 4. Cycles of 4 or 6 members are the most stable and have the stereofoms and the coordination numbers assigned to them in W.'s system. P.'s hypothesis has the following advantages: All bonds are of the same type, there being no difference between principal and supplemental valences; the difference between atomic and mol. complexes disappears, all union being atomic; all valences being regulated by position in the periodic system, the prediction of the number of isomers of a compd. is facilitated; the formation of complexes between mols. of different substances is readily explained by halving the number of total valences and by the presence of free polar affinities. This is illustrated by constitutional formulas of such a vast number of compds. as cannot be given in abstr. form. A few examples may suffice: H_2O may have the

following formulas: $H \cdots \cdots O \cdots \cdots H \cdots \cdots$ and $H \cdots \cdots O \cdots \cdots H$.

Of these the 2nd is the active form capable of existing only in union with other

groups, giving compds. like $H \cdots \cdots R \cdots \cdots H$. Similarly NH_3 has the inactive form

$H \cdots \cdots N \cdots \cdots H$ and the active form $H \cdots \cdots N \cdots \cdots H$. The formula of

NH_4Cl is therefore In the same way HNO_3 has the forms

and $\text{O}::\text{N}::\text{O}::\text{H}$. With a central atom M and

either a metalloid R or a metal Q we may have the complexes $\text{M}(\text{H}_2\text{O})_2\text{R}$, $\text{M}(\text{NH}_3)_2\text{R}$ and $\text{M}(\text{NO}_2)_2\text{Q}$ whose structures (omitting to indicate the free polar affinities) respect. are:

For $\text{CoCl}_2 \cdot \text{H}_2\text{O}$ the following formulas are possible: $\text{Cl} \cdots \text{Co} \cdots \text{Cl} \cdots \text{H}$ and and

$\text{H}::\text{Cl}::\text{Co} \cdots \text{O} \cdots \text{H}$. Of these the 1st is to be preferred as

better accounting for the easy removal of H_2O (by drying), since in this formula the H and the OH are nearer to each other. With P.'s free polar valences it is not necessary to assume that in Gombert's triphenylmethyl the central C is trivalent. For the other complexes and for the various speculations of P. the original must be consulted.

H. M. GORDIN.

Leakage of gases through quartz tubes (and Jena glass tubes). E. C. MAYER. *Phys. Rev.* 6, 283-91(1915).—No indications of leakage through Jena glass were obtained for temps. up to 800° , above which the glass became too soft for measurements. At the higher temps. it was not feasible to use pressures differing much from that of the atm., on account of softening. No leakage was found for quartz with H or O at atm. pressure and room temp. A quartz tube of the transparent variety was pervious to H at temps. from 330 to 710° and pressures from 740 to 780 mm. Hg. For N and O no leakage could be detected for pressures less than one atm. N did not seem to escape until a temp. of about 430° was obtained. At const. temp. the results for all gases showed considerable increase in leakage with increasing pressures. Under approx. equal conditions H leaks most rapidly and N least rapidly. It may be assumed that if quartz contains occluded gas, this gas is in equil. and forms a constituent part of the quartz itself. The occluded gas does not affect the diffusion process in any other manner.

E. B. MILLARD.

Transference number of the iron ion in ferrous chloride solution. A. STEPNICZKA-MARINKOVIC. *Monatsh.* 36, 831-43(1915).—The app. employed was that of Hopfgartner (*Z. physik. Chem.* 25, 119(1898); *Z. Elektrochem.* 4, 445) except that in place of the anode flask a 60 cc. U-tube was used with the Cd anode in the shorter arm. (The app. is not further described in this paper.—ABSTR.) HCl was used at various small concns. to prevent hydrolysis and delay oxidation. No attempt seems to have

been made to keep the temp. const. during the series; the individual expts. are at 14.0 to 22.5°. Total chloride was detd. by titration with AgNO_3 in the presence of NH_4SCN , Fe by standard I and $\text{Na}_2\text{S}_2\text{O}_8$, acid by difference. Values of the transference number of HCl were taken from Landolt-Börnstein's tables to correct for the transport of Cl ions from HCl, and the transference number of the Fe calcd. by difference. The anode portion only was analyzed, and only a single sample of the "middle portion" was analyzed, so that the possibility of mixing has not been considered. A large % change in concn. was produced, in some cases as great as 50%. It was found that the loss in wt. of the Cd anode did not agree with that calcd. from a Ag coulometer in series with the app., but since the difference was not greater than 3.6% in any case, a correction was applied for this, and the Ag coulometer was dispensed with. Twelve expts. were carried out at approx. N , 12 more at 0.5 N , and 12 at 0.172 N . The values for the cation transference number at these concns. were 0.300 ± 0.003 , 0.326 ± 0.005 , and 0.375 ± 0.006 , resp. Extrapolation to zero concn. gave 0.414 as the transference number, and from this the mobility of the Fe^{++} ion was calcd. as 46. From a calcn. after Riesenfeld and Reingold (*Z. physik. Chem.* 66, 672) the hydration of the Cl ion was 21 mols. of H_2O and that of the Fe ion 60 mols. H_2O . E. B. MILLARD.

Transference number of iron ion in ferric chloride solution. K. HOPFGARTNER. *Monatsh.* 36, 751-69(1915); cf preceding abstr.—The app. and method were essentially the same as above. HCl was again used to prevent hydrolysis, total Cl detd. by the Volhard method, Fe by titration with standard I, and acid by difference. In all, 60 expts. were made with concns. of Fe from 0.14 to 1.6 N , with the HCl between 0.06 and 0.19 N . From 30 expts. at 0.14 N the mean value for the transference number of the cation was 0.384 ± 0.003 , with the individual values between 0.414 and 0.358. The acid concn. was without influence on these values. At approx. 0.44 N the mean value for the cation was 0.359 ± 0.003 , and at the higher concns. 0.292 ± 0.004 . Extrapolation to zero concn. gave 0.396, corresponding to a mobility at 18° of 43 for Fe^{+++} . This points to the fact that the mobility of a highly charged cation is no greater than that of an "isomeric" ion with a smaller charge. This does not agree with Bredig (*Z. physik. Chem.* 13, 237(1894)) who gives $\text{Fe}(\text{CN})_6''' = 89.6$ and $\text{Fe}(\text{CN})_6'' = 90.3$. An increase in mobility with increasing charge is possibly prevented by an increase in hydration which more than compensates the increased charge. An equiv. of Cl ion at 0.137 N carries 6 mols. of H_2O and an equiv. of ferric ion 21 mols. No explanation of the smaller hydration of this ion than of ferrous ion was found, though possibly the presence of HCl may have influenced the hydration. E. B. M.

Anent a certain hypothesis on the condition of salts in solution. A. N. SAKHANOV. *J. Russ. Phys. Chem. Soc.* 47, 434-9(1915).—A criticism of Bogorodskii's theory of soln. (*C. A.* 9, 2178). The theory fails satisfactorily to explain those facts for the explanation of which the ionic hypothesis has been devised. According to B. a salt $\text{MR}(\text{M} = \text{metal}, \text{R} = \text{acid radical})$ is hydrolyzed by H_2O to mols. of $\text{M}(\text{OH})_n(\text{H}_2\text{O})_x$ and $\text{RH}_n(\text{H}_2\text{O})_y$, giving 2 mols. in soln. for 1 of solute taken, thus accounting for the factor i in vant Hoff's equation, but since salts of strong acids and strong bases are less hydrolyzed than those of weak acids and weak bases, the value of i (lowering of f , p , osmotic pressure, etc.) ought to be less for the former than for the latter, which is contrary to experience. For acids and bases B. assumes a depolymerization of $(\text{H}_2\text{O})_n$, but gives no reason why salts do no such thing. B. is taken to task for relying on the data of 2 authors which are admittedly in discord with those of other most reliable investigators. As to the concordance of the values of i as calcd. from thermochem. data with those calcd. upon the basis of B.'s theory, B. failed to give the concns. of his soln., so that his values are purely accidental. For certain salts such concordance does not exist at all. H. M. GORDIN.

Some electrochemical properties of solutions. A. BOGORODSKII. *J. Russ. Phys. Chem. Soc.* 47, 379-93(1915).—B. reiterates his claim that his theory of soln. (*C. A.* 9, 2178) as adequately explains the various phenomena accompanying soln. as the ionic hypothesis, and draws into the discussion the phenomena treated in the article referred to, those given in the preceding abstr., the heat of neutralization, diffusion, the origin of e. m. f. and the action of neutral salts in soln. on metals. H. M. G.

Depression of the freezing point. V. A. VIL'DE AND A. YA. BOGORODSKII. *J. Russ. Phys. Chem. Soc.* 47, 373-9(1915).—The abnormal depression of the f. p. of electrolytes in dil. soln., indicating the presence of almost double the number of mols. of solute taken, is usually explained by assuming a dissociation of the solute into ions. Citing from literature the numerous objections to the ionic hypothesis, V. and B. reject it, and offer the following explanation of the phenomenon: Liquid H_2O has the

formula H_2O-CH_2 , in which O is tetravalent. In connection with Thomsen and Gantsch's view of the existence in the soln. of HCl in H_2O of an hydronium group H_3O ($H_2O + HCl = H_3OCl$), it is assumed that when an acid HR or a base MOH is dissolved in H_2O the reactions are, resp.: $(H_2O)_2 + HR = H_2O.R + H_3O.OH$; $(H_2O)_2 + MOH = H_2MO.OH + H_3O.OH$, giving 2 mols. for each mol. of acid or base taken. Similarly the soln. of a salt in H_2O is: $(H_2O)_2 + MR = H_2O.R + H_2MO.OH$. In concd. soln. the 2 mols. resulting from 1 of salt retain their opposite chem. natures, forming 1 undissociated mol., either $H_2MO.O(R)(H).OH$, or $(H_2MO)(RH_2O)OH$, while in dil. soln. or at an elevated temp. the 2 mols. are free. This explains why hydrates like $MR.2H_2O$ or $MR.H_2O$ sometimes sep. out when the soln. of MR in H_2O is warmed. The production of $H_3O.OH$ by warming $(H_2O)_2$ also accounts for the greater elec. cond. of hot than cold H_2O , while the complete dissociation of $(H_2O)_2$ into simple H_2O mols. at a still higher temp. accounts for the absence of cond. in steam. Further corroboration was found in detns. of the lowering of the f. p. of anhydrous AcOH by dissolving in it CuO. The results showed that the depression was 1.37 times greater than corresponds to 1 mol. of CuO, so that we must assume that the hydrate $(AcO)_2Cu$ formed in the reaction gives off some of its H_2O to the acid, producing from 100 mols. of hydrate 37 mols. of anhydrous salt, 37 mols. of hydronium acetate and 6 mols. of undissociated hydrate. H. M. GORDIN.

True specific volume and the number of molecules in homologous series of organic compounds. W. HERZ. *Z. Elektrochem.* 21, 457-8(1915); cf. *C. A.* 9, 3000.—Assuming that the mols. are spherical, the vol. actually occupied by them may be expressed as a function of the dielectric const. of the liquid by means of the equation $\mu = (D - 1)(D + 2)$, where μ is the vol. On dividing μ by the d., the true sp. vol. is obtained. This has been calcd. from existing data for a number of series of compds. In each homologous series the dielectric const., as well as the μ and sp. vol. values, decrease as the series is ascended. In the light of the rule expressing the power of a liquid to act as a dissociating solvent, this means that the solvent power decreases also as the series is ascended. The rule fails completely for the hydrocarbons, since their dielectric consts. are practically the same, and of small magnitude. A mean value of the mol. radius was calcd. as 10^{-8} cm., and from it values of the number of mols. in a were calcd. for each series. The numbers decreased as the series was ascended, that at least the principle of the calcn. was correct. Avogadro's N was found to be 60×10^{21} . E. B. MILLARD.

Lecture experiment to demonstrate a case of decrease of reaction velocity with increase of temperature. ANTON SKRABAL. *Z. Elektrochem.* 21, 461-3(1915).—"reaction" is the resultant of the 3_2 reactions taking place when HIO_3 and H_2SO_4

mixed: (I) $\text{IO}_3' + 3\text{SO}_3'' = \text{I}' + 3\text{SO}_4''$, (II) $\text{IO}_3' + 5\text{I}' + 6\text{H}^+ = 3\text{I}_2 + 3\text{H}_2\text{O}$, (III) $\text{I}_2 + \text{SO}_3'' + \text{H}_2\text{O} = 2\text{I}' + \text{SO}_4'' + 2\text{H}^+$. If the reaction is carried out with NaHSO_3 and HIO_3 , it has a normal temp. coeff., which may be shown by immersing 2 sep. portions of the mixt. in baths of different temps. If an excess of Na_2SO_4 is added, the mixt. in the cooler bath flashes blue in the presence of starch several min. before that in the warmer bath. For 12 and 30° the difference was quite marked. The final condition of equil. is not noticeably dependent on the temp. E. B. M.

New form of dilution law for electrolytes. G. v. GEORGIEVICS. *Monatsh.* 36, 771-94(1915); *Z. physik. Chem.* 90, 340-58(1915).—An equation similar to $C_i^n/C_s = K$ has been used in most discussions of the "diln. law." In this paper values of n have been calcd. for numerous acids and salts, and it was found that most mineral acids at equal concns. had similar values. Increase in n values was perhaps due to the adsorption of H_2O by the undissociated mols., or the formation of a H_2O film over the ions. There was a parallelism between the values of n and the viscosity of the solns., and hence the values are detd. by the affinity between the acid and H_2O (cf. C. A. 9, 2171, 2340). No such similarity between affinity for H_2O and n was found for salts, where the values were somewhat more uniform. In the absence of influences which render the equation invalid, the diln. law is $C_i/C_s = K$, but some of these influences (such as hydration, affinity of the electrolyte mols. for H_2O , etc.) may cause the n values to be as great as 7.8 in place of unity. E. B. MILLARD.

Interpretation of the labile portion of the theoretical isotherm. G. BAKKER. *Z. physik. Chem.* 90, 359-80(1915).—A mathematical paper. H. J. C.

Determination of the fusion points of calcium sulfate dihydrate, barium chloride dihydrate, sodium carbonate monohydrate, sodium tetraborate pentahydrate, copper sulfate hydrates and carnallite by means of the electrically heated pressure apparatus. ERNST JÄNECKE. *Z. physik. Chem.* 90, 265-79(1915); cf. C. A. 10, 132.—The m. ps. of the above mentioned hydrates have been detd. by means of the electrically heated pressure app. The m. p. of gypsum and of carnallite agrees with previous detns. Detns. have been made for the first time of incongruous m. ps. of $\text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{O}$, $\text{Na}_2\text{B}_4\text{O}_7 \cdot 5\text{H}_2\text{O}$, $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ and $\text{CuSO}_4 \cdot 3\text{H}_2\text{O}$. From the data obtained, the existence of an incongruous m. p. of $\text{CuSO}_4 \cdot \text{H}_2\text{O}$ and the formation of an unknown hydrate with less H_2O ($\text{CuSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$) are probable. H. JERMAIN CREIGHTON.

The transition points of silver nitrate, ammonium nitrate and potassium nitrate. ERNST JÄNECKE. *Z. physik. Chem.* 90, 280-95(1915); cf. preceding abstr.—The known transitions of AgNO_3 , NH_4NO_3 and KNO_3 have been confirmed by means of an electrically heated pressure app., and a new modification for KNO_3 has been found. The transitions are only partially manifested by an uneven change in the pressure. In many cases the change was found gradual over a temp. interval, and the pressure curve before and after rectilinear. In such cases the intersection of the rectilinear portions corresponds to the transition point. H. JERMAIN CREIGHTON.

The transition phenomena of isomorphous mixtures of potassium chloride-sodium chloride and silver chloride-sodium chloride and their complete condition diagram. ERNST JÄNECKE. *Z. physik. Chem.* 90, 296-312(1915); cf. preceding abstr.—New transition points have been detd. in the isomorphous system KCl-NaCl , by means of the electrically heated pressure app., and the app. has also been used to det. the unknown transition curve for AgCl-NaCl mixts. H. JERMAIN CREIGHTON.

The transitions of the metals tin, zinc, bismuth, cadmium, copper, silver, lead and antimony, determined by means of the new electrically heated pressure apparatus. ERNST JÄNECKE. *Z. physik. Chem.* 90, 313-39(1915); cf. preceding abstr.—The values found for the transitions of Sn, Zn, Bi, Cd, Cu, Pb and Sb by Cohen and his

co-workers have been confirmed. A new transition of Ag has been found, and it has been shown that this is in good agreement with previous expts. It is pointed out that the explanation of the transition interval is found in Smits' new theory of allotropy. It is shown that it is these transition intervals that have hitherto prevented the recognition of these transitions by means of heating and cooling curves.

H. JERMAIN CREIGHTON.

Thermal analysis of binary mixtures. E. BAUD. *Bull. soc. chim.* 17, 329-45 (1915); cf. *C. A.* 7, 1316; 8, 605.—Heats of mixing have been detd. for 33 mixts. of 14 org. compds. of widely differing types at several concns., and a set of substances has been found for which the heat of mixing may be expressed by the equation $dQ = K \cdot x(1 - x)$, where x is the mol. fraction of one of the constituents and K is a const. for each pair of substances. Mixts. of cyclo- C_6H_{12} with C_6H_6 , C_2H_5Br , $CHCl_3$, $n-C_6H_{14}$, and $HOAc$, and of C_6H_6 with C_2H_5Br , obeyed this rule but most of the other substances did not. In most of these latter cases dQ had a max. value at $x = 0.5$, or in an equimolar mixt. Only those substances which follow this modified law of Biron were considered as physical mixts., the others were influenced either by chem. reactions, depolymerization or association. In the ideal cases it is possible to predict roughly the soly. of the solid form of one of the components in the liquid of the other from their phys. properties. The exptl. method was not described. E. B. M.

Negative-hydroxide sols. H. FREUNDLICH AND W. LEONHARDT. *Koll. Chem. Beihefte* 7, 172-211 (1915).—Colloidal solns. of $MoO(OH)_3$ ($MoO_3 \cdot H_2O$ in original but correction in *Kolloid-Z.* 17, 112 (1915) gives $MoO(OH)_3$) and of V_2O_5 were investigated. The sol of $MoO(OH)_3$ was prepared according to Pechard (*J. B.* 1894, 1222) by reducing $KMoO_4$ with HI and pptg. with NH_4OH . The sol showed distinct colloidal properties. It did not dialyze through parchment, was coagulated with electrolytes and the wandering of the particles toward the anode showed a decided negative charge of the particles. Expts. on the coagulation of the colloid showed that a total pptn. by means of addition of electrolytes was not possible. The sol remained yellow, due most probably to the existence in the original sol of larger and smaller particles which coagulated with more or less ease. Instead of detg. the amt. of electrolyte necessary to cause total coagulation of the colloid, the amt. of electrolyte which will just produce a cloudiness in the sol in a given time ("Trübungswerte") was detd. The results obtained were as expected from negative colloids (predominating influence of the cation). The "Trübungswerte" diminishes with increasing valences. Of cations with the same valences only those with valences of 2 and 3 gave the same value for the "Trübungswerte." The monovalent cations decreased in value 100-fold in the order from Li to Cs . Organic cations and the heavy metal cations react more strongly than their valences call for. The ease with which the coagulates, produced by the addition of different electrolytes, can be reconverted to the colloid form is in proportion to the coagulability of the electrolyte. Coagulates formed by monovalent cations are easy to peptize while those of the higher valent cations are more difficult to reconvert to colloidal form. The lower the temp. the easier the reversibility. The colloidal soln. of V_2O_5 was prepared according to the method of A. Ditte (*Compt. rend.* 101, 699 (1885)) by moderately heating NH_4VO_3 in a Pt crucible, and also according to the method of W. Biltz (*Ber.* 37, 1098 (1904)) by pptg. the V_2O_5 from NH_4VO_3 with HCl . The colloid V_2O_5 is negative. The surface tension of the colloidal soln. is about the same as that of H_2O . In reflected light the sol appears to contain small, shiny crystals and it shows strong rotation of polarized light. This is because the colloid particles are elliptical instead of round. Crystals could not be carried out because not all of the V_2O_5 was coagulated. Part of the V_2O_5 was not in colloidal form. For this reason the values were detd. as in the $MoO(OH)_3$.

expts. and similar results obtained. Expts. to reconvert the coagulates to colloidal form gave results similar to those in the case of $\text{MoO}(\text{OH})_3$. The coagulation of the negative V_2O_5 sol by the positive $\text{Fe}(\text{OH})_3$ and $\text{Al}(\text{OH})_3$ sols and *vice versa* was studied. There is no sharp point of relative concns. where coagulation takes place. A smaller amt. of V_2O_5 sol is necessary to coagulate the $\text{Fe}(\text{OH})_3$ or $\text{Al}(\text{OH})_3$ than was found using As_2S_3 and Sb_2S_3 sols. Evidently there is a relatively greater charge of electricity in the V_2O_5 sol than in the As_2S_3 or Sb_2S_3 sols.

W. F. ZIMMERLI.

Studies on the molecular statics of emulsions and their connection with the Brownian movement. M. v. SMOLUCHOWSKI. *Sitzb. Akad. Wiss. Wien, Abt. IIa* 123, 2381-405(1914).—Mathematical. Formulas are deduced which represent quant. the variation with time in the number of particles of an emulsion in a given volume, their agreement with Svedberg's observations being satisfactory. The phenomena are analogous to the Brownian movement and these formulas may be used for the indirect detn. of the Brownian mobility.

G. L. WENDT.

An absolute determination of capillarity constants with the Jäger apparatus. E. MARTIN. Univ. Vienna. *Sitzb. Akad. Wiss. Wien, Abt. IIa* 123, 2491-507(1914).—To eliminate the untrustworthy constant β in Jäger's formula, M. derives the following formula for the capillarity constant: $\alpha = aa_1gs/2(a - a_1)[H + 2(a - a_1)/3]$, in which α and a_1 are the radii of the capillaries, H the vertical distance between their tips, s the sp. gr. of the liquid, and g the gravitation const. This formula gives the following values for α : ether 18.36, EtOH 22.18, $\text{C}_6\text{H}_5\text{CH}_3$ 29.82, C_6H_6 29.23, H_2O 72.80, 18.34% NaCl soln. 78.71, 15.22% NaCl soln. 77.81, CS_2 33.87, CHCl_3 29.21. Small variations from the vertical position have no effect, but the plane of the orifice should always be normal to the axis of the capillary.

G. L. WENDT.

Heat and the occupation of space. G. A. HAGEMANN. *Z. Elektrochem.* 21, 493-5(1915).—The mol. vol. of Ca is 25 cc. ($d. = 1.6$), that of H_2 is 22480 cc., and the mol. vol. of the resulting CaH_2 ($d. = 1.7$) is 24.78 cc. The 22.5 l. of H has completely disappeared, it has lost its space-filling energy without being at abs. zero, or the H atom has become so small that it can find place for itself within the Ca atom. Brönsted has calcd. (on grounds to be published later) that the heat of formation of CaH_2 is a multiple of 11400 cal., and measured the heat as 45100. There is also thought to exist a compd. CaH with a heat of formation of 2×11400 cal., or half of that for CaH_2 . The total "volume energy" of H_2 is accordingly 45600 cal., and $E_H = 22800$ cal. The quantity of heat 11400 cal. appears to have special significance, for when 2 vols. of H_2 and 1 vol. of O_2 combine to form H_2O vapor the heat is 57000 cal., or 5×11400 . If this quantity of H_2O vapor is cooled to 4° another 11400 cal. of heat is given out, total 68400 cal. H. attempts to answer the question, "where does this heat come from?" and claims that it cannot come equally from the O and H , since they have different latent heats of evapn. Since at 100° the H_2O vapor occupies the same vol. as the H_2 from which it was formed, it may be assumed that all of the heat came from the O , and that its vol. has become so small that it can find space within the vol. of the 2 H atoms. It is impossible to say whether this is the total energy of the O , but the mol. vol. of O gas is 14 and that of liquid O is also 14. (No units are given, but presumably liters in the first case and cc. in the second.—ABSTR.) The O in H_2O_2 was also calcd. to be in the form of ozone, from the contraction in vol. during its formation from H and O .

Period of induction and passivity of zinc. M. TZENTNERSHVER AND YUL. DRUKHER. *J. Russ. Phys. Chem. Soc.* 47, 439-69(1915); see *C. A.* 9, 3160. H. M. G.

Metastability of sodium. ERNEST COHEN AND G. DE BRUYEN. *Chem. Weekblad* 12, 92(1915).—In *C. A.* 9, 987 the temps. should read in both cases 0° to 90° instead of 70° to 80° .

E. H.

Electrostatic measurement of electrode potentials. A. W. EWELL. *Phys. Rev.* 6, 271-82(1915).—The electrolyte was contained in a glass or quartz flask of 50 to 150 cc. capacity, covered outside (except the neck) with a metallic film of Ag or Al which could be connected to the earth, to an electrometer, or to a source of known potential. If the electrode was initially at zero potential, it would acquire a potential equal to its natural abs. potential with reference to the particular electrode when that electrode was earthed and introduced into the electrolyte. A charge of somewhat different potential would be induced upon the metallic film upon the outside of the flask, and the deflection of the electrometer would be proportional to this potential, and thus the potential of the electrolyte could be obtained from a calibration of the electrometer. Losses of charge due to poor insulation rarely exceeded 2% per min. Volta effects were believed to have been eliminated, as well as static charges on the electrolyte. After standing some hrs. it was assumed that the electrolyte had the same potential as the surrounding wire cage. The potential of Zn in N $ZnSO_4$ was -1.05 ± 0.02 v.; for Zn in 0.5 N H_2SO_4 , -1.04 v.; Ag in N $AgNO_3$ was $+0.49 \pm 0.03$ v.; Cu in N $CuSO_4$, -0.02 v., and Cu in 0.5 N H_2SO_4 , -0.05 v. The results indicate that the potential of a metal in a homogeneous soln. of one of its salts at N concn. is about 0.5 v. more negative than the value deduced from the electrocapillary method and usually found in tables. Increasing the concn. of the salt soln. contained in a glass vessel appears to lower the potential of an electrode of the metal of the salt. E. B. MILLARD.

Products of addition and photochemistry of hydrated chromic chloride. V. V. KURNIOV. *J. Russ. Phys. Chem. Soc.* 47, 469-81(1915).—Under the influence of light

the green hydrate of $CrCl_3$ gradually changes to the violet:
$$\left[\begin{array}{c} Cl_2 \\ Cr \\ (H_2O)_4 \end{array} \right] Cl + 2H_2O = \left[Cr(H_2O)_6 \right] Cl_3$$
 (cf. Werner and Gubser, *Ber.* 34, 1579). The change was followed

spectrometrically and by detns. of the changes in elec. cond., both showing gradually increasing ionization. This is in accord with K.'s views on chem. compds. in general and mol. complexes in particular as outlined by him in former publications (*C. A.* 6, 1409) and in his book "Theory of Ammoniates," Ekaterinoslav, 1905. H. M. G.

Polychromatism of silver. R. E. LIESEGANG. *Z. wiss. Phot.* 14, 343-6(1915).—Similar to the behavior of $AgCl$ -gelatin mixts. on treatment with developers, $AgNO_3$ -gelatin hydroquinone mixts. on solidifying give a sequence of colors passing from yellow to blue. The rapidity of this change is increased by increased $AgNO_3$ concn. and temp. and decreased by additional gelatin. The age of the hydroquinone soln. has considerable influence. The color changes are ascribed to the increase in the size of the Ag molecular complexes. This property of Ag is applied in the R. y Cajal method of impregnating brain sections with silver by alternate immersions in $AgNO_3$ and hydroquinone solns. E. C. MCKELVY.

Measurements of the wave lengths on the international system in the arc spectra of the elements in the red and infra-red. L. JOAZE M. EDER. *Sitzb. Akad. Wiss. Wien, Abt. IIa* 123, 2289-311(1914).—Tables are given enumerating the lines between λ 8560 and λ 6341 for the elements: Li, Na, K, Cs, Rb, Ca, Sr, Ba, Zr, La and Ce.

G. L. WENDT.

Single-line spectra of the elements. J. C. MCLENNAN. *Engineering* 100, 344-5(1915).—Non-luminous vapors of Hg give a strong, symmetrically spaced band at 1849.6Å., a diffuse complex band at 2338Å. (consisting of a band extending from 2313 to 2320, one at 2326 and a wider one between 2330 and 2338Å.) and an asymmetrical band at 2536.72. Expts. confirmed the work of Wood and Guthrie as to the existence of a

strong asymmetrically spaced band at 2288 and a narrow, sharply defined one at 3260.17Å. Non-luminous Zn vapor gave a strong symmetrically spaced band at 2139.3, and a very narrow, sharp one at 3075.99Å. Spectra consisting of a single line can be obtained with Hg, Cd, Zn and Mg vapors if these were bombarded with electrons having kinetic energies acquired in potential falls of between 5 and 10 v. The wave lengths of these single lines were Hg 2526.72, Mg 2852, Zn 3076, Cd 3260. If the vapors of these metals were bombarded with electrons having slightly greater kinetic energies, the many-lined spectra were emitted. These points are further discussed in *C. A.* 9, 3155. E. B. MILLARD.

The magnetic rotation of the plane of polarization in titanium tetrachloride. L. H. SIERTSEMA. *Verslag Akad. Wetenschappen* 23, 1259-64(1915).—In the abstract of this paper in *C. A.* 9, 3165 the formula "CCl₄" at the beginning should read "TiCl₄." E. J. C.

Magnetochemistry of inner-complex compounds. J. LIFSCHITZ AND E. ROSENBOHM. *Z. Elektrochem.* 21, 499-501(1915).—A new, independent, and generally applicable method of demonstrating inner complexes is the detn. of magnetic susceptibility. The following values of $\chi \times 10^{-8}$ were detd. to within 1% by the Curie method: Cu(OAc)₂·2NH₃ + 7.00, Cu(CH₃NH₂CO₂)₂ + 6.39, Cu(CH₃CHNH₂CO₂)₂ about +4.00, CuCl₂·2C₆H₅N + 4.80, CuCl₂·2 (antipyrine) + 2.76, Cu(CH₃OH.CO₂)₂·H₂O + 7.08. The inner-complex Cu salts give either much higher or much lower values than the normal salts. Surprising differences are obtained with conjugated alkali and alk. earth salts, especially chromoisomeric compds. Pascal (*C. A.* 6, 2599, 2710) found differences between the magnetic susceptibilities of the red and colorless Ag salts of tribromophenol. Changes in the sign of the susceptibility are found in isomers with different distributions of the secondary valences, as in the salts of diphenylthioviolic acid, but the differences are very small when the chromoisomeric compds. have similar inner structures. The greatest differences are not due to a change from oximinoketone back to nitrosoenol, but to the different satns. of the secondary valences. E. B. MILLARD.

Conversion tables for Saybolt universal, Engler and Redwood viscosimeters. C. W. WADNER. *Proc. Am. Soc. Testing Materials* 15, 284-94(1915).—Report of an extended investigation to det. the necessary factors, which are given. E. W. B.

3. RADIOACTIVITY.

WILLIAM H. ROSS.

Radioactivity of underground waters in Providence and vicinity. P. B. PERKINS. Brown Univ. *Science* 42, 806-8(1915).—Measurements of the radioactivity of the waters from 13 springs and wells in Providence and vicinity gave values which, when expressed in equiv. amts. of Ra, varied from 0.03 to 57.93 $\times 10^{-10}$ g. of Ra per l.

W. H. ROSS.

Practical methods for the determination of radium. II. The emanation method. S. C. LIND. Bur. Mines. *J. Ind. Eng. Chem.* 7, 1024-9(1915); cf. *C. A.* 9, 1714.—Methods are given for the chem. treatment and other manipulations involved in preparing Em for electroscopic measurements. A soln. containing an excess of Ba in a rather high concn. of HNO₃ is recommended as the best medium for storing Ra in soln. without danger of loss through pptn. Ra solns. for use in analysis and which are low in Ba and HNO₃ should therefore have these reagents added before allowing to stand to collect Em. In cases where no Ba but an excess of a Ba precipitant, as sulfate, is present, it is suggested to add a suitable vol. of the Ra sample to a soln. containing

Ba in excess; the ppt. is filtered off, and the filtrate acidified with HNO_3 , boiled and sealed; the ppt. of BaSO_4 is fused with $\text{Na}_2\text{CO}_3\text{-K}_2\text{CO}_3$ mixture, sealed in a glass tube for a known time, and the accumulated Em then drawn into the electroscope by suction before and after treatment of the fusion with HNO_3 heated to boiling. For convenience the filtrate may be sealed at the same time as the fused ppt. in order that both lots of Em may be introduced into the same electroscope. Instead of boiling the fused mass in acid as in the analysis of Ra-bearing BaSO_4 , or other insoluble material, fusion may be employed both before and after the collection of the Em if preferred.

W. H. ROSS.

The ionization tracks of alpha rays in hydrogen. J. C. McLENNAN AND H. V. MERCER. Univ. Toronto. *Phil. Mag.* 30, 676-83 (1915).—Photographs made by the method of C. T. R. Wilson (*C. A.* 7, 932, 1661, 2157) are reproduced showing the paths of α -rays from Po in H. The paths are similar to those in air, and show the same sharp deflections due to individual at. encounters, but there is no evidence of the path of the ionized H nucleus which is supposedly given a high velocity by the impact (cf. Marsden, *C. A.* 8, 2307). The ionization clouds may be obtained equally as well by the condensation of alc. vapor as of water vapor.

G. L. WENDT.

The velocities of the alpha particles from thorium active deposit. A. B. WOOD. Univ. Liverpool. *Phil. Mag.* 30, 702-10 (1915).—The magnetic deflection of the α -particles from the active deposit of Th indicates a ratio between the velocities of those from Th C_1 (range = 4.8 cm.) and those from Th C_2 (range = 8.6 cm.) of 0.832. On Geiger's relation ($v^3 = kR$) this value should be 0.826 if the accepted range is correct; W. proposes that the true range for Th C_1 is 4.95 cm. A comparative deflection of the α -particles from Ra C shows their velocity on the same scale to be 0.932, which agrees with Geiger's relation. Using Rutherford's value for this last velocity, 1.922×10^9 cm./sec. (*C. A.* 9, 21), the velocity for the rays from Th C_1 is 1.714×10^9 , and from Th C_2 , 2.060×10^9 cm./sec. The photographs indicate that Th C_2 gives about twice as many α -particles as does Th C_1 . There is no evidence for a difference in mass of the 2 sets of particles.

G. L. WENDT.

Ionic mobilities in hydrogen. A. M. TYNDALL. Univ. Bristol. *Phil. Mag.* 30, 743-4 (1915).—A discussion of the work of Haines (*C. A.* 10, 13) which confirmed and amplified some measurements previously published by Chattock and the author (*Phil. Mag.* 19, 453 (1910)).

G. L. WENDT.

Galvanic cells with lead isotopes. G. v. HEVESY AND F. PANETH. Radium Inst., Vienna. *Monatsh.* 36, 795-803 (1915); cf. *C. A.* 9, 175.—If in an exactly compensated cell, $\text{HgCl} \mid \text{Pb}(\text{NO}_3)_2 \mid \text{PbO}_2$, the $\text{Pb}(\text{NO}_3)_2$ soln. is replaced by a similar soln. of $(\text{Ra G})(\text{NO}_3)_2$, prepared from Hönigschmid's pure Ra G from Morogoro (*C. A.* 9, 3026), there is no change in the compensation greater than 10 microv. The e. m. f. of the cell, $\text{PbO}_2 \mid \text{Pb}(\text{NO}_3)_2 \mid (\text{Ra G})(\text{NO}_3)_2 \mid (\text{Ra G})\text{O}_2$, is less than 10 microv. The diffusion potential between $(\text{Ra G})(\text{NO}_3)_2$ and $\text{Pb}(\text{NO}_3)_2$ is probably less than 1 microv. Ra G and Pb are therefore electrochemically replaceable.

G. L. W.

Atmospheric electricity. LII. Measurements of the mobilities and coefficients of recombination of ions in the open atmosphere. K. W. F. KOHLRAUSCH. Univ. Vienna. *Sitzb. kais. Akad. Wiss., Wien, Abt. IIa* 123, 2321-48 (1914).—Using a tubular ionization chamber with a Wulff electrometer and a sensitive anemometer, K. found by the stream method that the mobility and the coeff. of recombination of ions in the open atm. are const. within 15%, are independent of meteorological conditions and are always proportional to each other. The mean values found for the mobility and the coeff. of recombination of the ions are, resp., 1.05 cm./sec. per v./cm., and 1.69×10^{-1} . The number of ions is greater in cloudy weather and with rising air currents but de-

creases with a rise of relative humidity. Mean values at Seeham in Salzburg are 664 for positive ions, and 648 for negative ions. Both a high wind and a heavy rain increase the number of negative ions faster than the positive, and the mobility of the former is lessened so that the air takes up a negative charge. G. L. WENDT.

Copper and tungsten X-ray target. W. D. COOLIDGE. U. S., 1,162,341, Nov. 30. The target is formed of a body portion of Cu with a facing of wrought W autogenically joined with the Cu. Cf. C. A. 9, 3027.

The electrochemical industry in Russia. ANON. *Chem. Trade J.* 57, 366(1915).—Russia has exported large quantities of Mn ore to Germany and imported Al, Al products and ferro-alloys from there. The industry may be developed in Russia by making use of the natural water power and the extensive lignite and peat deposits. W. H. BOYNTON.

Review of the English electrical industry. C. P. SPARKS. *Electrician* 76, 282-5 (1915).—Includes chapters on insulating compds., incandescent lamps, elec. instruments, etc. C. G. F.

Steel making in electric furnace. J. H. GRAY. *Iron Age* 96, 1238-9(1915).—A general discussion of the properties of elec. furnace steel. There are 40 elec. furnaces in America, 27 of the Heroult type. The av. size is greater than that of the European furnaces. W. H. BOYNTON.

Electric steel furnace of new design. R. S. WILE. *Iron Age* 96, 866-8(1915).—The Wile furnace is designed for 3-phase systems because most of the supply systems are 3-phase. Two electrodes enter at the top and one at the bottom. This gives better circulation than the 3-top electrode type of furnace and also facilitates the melting of the cold charge. The bottom electrode is graphite covered with a conducting mixt. of magnesite and tar. The furnace is operated with few abnormal variations of load and can be easily regulated by hand. This furnace is in successful operation in melting Sn from Bolivian concentrates, Ni-Fe alloys and Co for stellite. A typical run shows

the total time of melting and refining cold scrap to be $4\frac{1}{4}$ hrs., with a consumption of 868 kw.-hrs. per ton and an electrode consumption of \$0.50 per ton. The product was a 0.12% C steel. Drawings and photographs are given. W. E. RUDER.

Electric steel direct from titaniferous iron ores. ANON. *Iron Age* 96, 1416 (1915).—An account of the steel produced direct from Fe ore in an elec. smelter at Belleville, Ont., Can. A preheater, consisting of 2 wrought Fe pipes within to allow the charge to slide easily down the heated portion, utilizes the heat from the waste gases of the smelter. The furnace is charged from the upper floor into the preheater, the charge being Fe ore, limestone and charcoal, crushed to pass a 1-in. mesh. It operates on a 2-phase current, the transformers being connected by what is known as the Scot connection. The ore treated is practically free from S and P and contains 7.5 Ti, 0.11 V, 0.34 Ni with some Cr and Mn and 50% Fe. It is claimed that by this process W, Cr and other alloys for high speed tool steel can be made directly in 1 operation by the mixing of the crude ores. The capacity of the furnace is 1 ton; a 3-ton unit for making tool steel and steel castings is contemplated. I. C. MATTHEWS.

Electric steel in Germany. ANON. *Elec. Rev. West. Elec.* 67, 982(1915).—The total production of elec. steel in Germany in 1914 was 90,000 tons, only 5,800 tons less than the total output of crucible steel. Twenty elec. steel plants were in operation, 10 having Siemens-Halske furnaces, 7 Heroult furnaces, 2 Nathusius furnaces, and 1 a Keller furnace. Of these 20 installations, 8 are producing high-grade elec. steel to supplant crucible steel, and the remaining 12 use the elec. furnace to melt ferro-Mn. Four of these 12 are of the induction type, 3 are Heroult, 2 are Keller furnaces, while one each of the Rombach, Girod and Nathusius types are employed. C. G. F.

Germany's electric steel output much increased. ANON. *Iron Age* 96, 1447 (1915).—Production statistics with special reference to the effect of the war.

I. C. MATTHEWS.

Electrical applications of aluminium. J. W. RICHARDS. *J. Elec. Power Gas* 35, 288(1915).—On a practical basis Al may replace Cu conductors by increasing the diam. $\frac{1}{4}$. The Al conductor will have 48% of the wt. of the Cu it replaces. This increased diam. is objectionable in windings where space is important. It is also harder to make good contact with Al than with Cu, especially in chem. plants and so it must be more frequently cleaned. For equal conducting power an Al cable is 0.8 as strong as Cu. This is more than offset, however, by the fact that Al is only half the wt. of Cu. The increase in span can therefore be increased 50% with the same dead wt. on the supports and the same factor of safety. The saving in supports, insulators and erection cost is in general far more important than the cost of the cable itself. Near the coast both Al and Cu should be insulated to prevent corrosion. W. E. RUDER.

Commercial nitrogen fixation; a polemical note. S. PEACOCK. *Chem. Eng.* 22, 147-8(1915); cf. *C. A.* 9, 1431.—No N-fixation process yet proposed can compete with coke by-product NH_3 . A combination process which will fix N and accomplish one or more additional useful purposes is needed. The end-product must be constant in compn., sol. in H_2O , not deliquescent, and yield products not readily assuming undesirable forms. The factory cost must be less than 5 cents per lb. of combined N figured as NH_3 .

W. H. BOYNTON.

The electrolysis of nitric, sulfuric and orthophosphoric acids, using a gold anode F. H. JEFFERY. Cambridge, England. *Trans. Faraday Soc.* (advance copy) 9 pp. (1915).—Using an electrolyte made by dilg. each 100 cc. HNO_3 (d. 1.42) with 100 cc. H_2O , and a Pt cathode, Au was dissolved from the anode, forming a green compd. which was reduced to metallic Au by the H_2 dissolved in the Pt cathode. In all the other expts. the cathode was inclosed in a porous cup. The anolyte (550 cc.) was

mechanically stirred. Acids of various concn. and various currents and c. ds. were used. The anolyte and catholyte were the same. No Au was deposited on the cathode, but Au penetrated part way through the porous cup, causing a purple color. The Au went into soln. as complex anions. Small lemon-yellow crystals were recovered, and proved to be auri-nitric acid, $\text{HAu}(\text{NO}_3)_4 \cdot 3\text{H}_2\text{O}$. 0.0104 gram-atoms of Au dissolved per faraday, when the current was 1 amp. and the anode area 2×4.61 sq. cm., but when the current was 0.5 amp., then 0.0113 g.-atoms dissolved. Using an electrolyte made by dilg. each 100 cc. HNO_3 (d. 1.42) with 200 cc. H_2O , a current of 1 amp. and an anode area of 2×7.10 sq. cm., 0.0118 g.-atoms Au went into combination per faraday. A red-brown powder sepd.; it was a mixt. of hydrated Au_2O_3 and Au_2O . Next, still more dil. HNO_3 was used with a current of 1 amp. and anode area of 2×9.80 sq. cm.; Au going into combination was 0.0114 g.-atoms per faraday. The same brown powder sepd. With acid corresponding to 1 cc. HNO_3 to 10 cc. or more of H_2O , hydrated Au_2O_3 was formed, but no aurous compd. With dil. acids, the catholyte was reduced to NH_4NO_3 , which diffused to the anode, and there produced an explosive compd. Two concns. of H_2SO_4 were used, one of equal vols. of concd. acid and H_2O , and the other of 1 vol. acid to 7 vol. of H_2O . The anolyte turned green and Au went into soln. as complex anions. The more concd. anolyte contained fine yellow Au powder. There was no Au deposit on the cathode, but a brown deposit composed of hydrated Au_2O_3 and Au_2O formed at the anode. Using a 15% soln. of H_3PO_4 , a current of 1 amp. and an anode area of 2×6.84 sq. cm., it was found that no Au was deposited on the cathode, the anolyte remained colorless and the same brown deposit formed on the anode.

SHERMAN EASTMAN.

Nickel plating. F. C. MATHERS, E. H. STUART AND E. G. STURDEVAND. *Trans. Am. Electrochem. Soc.* (advance copy) (1915).—The following bath gave best deposits: $\text{Ni}(\text{NH}_4)_2(\text{SO}_4)_6$ 4%, NiSO_4 14%, H_3BO_3 1–3%, MgCl_2 2% and $(\text{NH}_4)_2\text{C}_2\text{H}_3\text{O}_7$ 0.2–0.3%. At a c. d. of 1.6 amp. per sq. dm., this bath plates a thickness of 0.0025 cm. (0.001 in.) in $1\frac{1}{4}$ hour. The addition of H_3BO_3 increases the current that can be used without blackening or burning the deposit. The $(\text{NH}_4)_2\text{C}_2\text{H}_3\text{O}_7$ keeps the soln. clear and free from sludge (Fe_2O_3 and sulfates from anodes), making possible the use of a more shallow tank and less soln. The expts. were carried out in 350 cc. beaker using about 300 cc. for the plating bath. Two anodes (92% Ni + 6% Fe) or Ni strip (98%) were used. It is best to use the purest Ni for anodes (electrolytic Ni) to avoid impurities coming into the bath which give discolored deposits. The anodes were suspended by Pb strips and placed in cloth bags. The distance between anodes was 4.5 cm.; from cathode to each anode was 2.25 cm. The cathodes were of sheet Cu. Electrolysis was at room temp. The addition of MgCl_2 or NiCl_2 makes the anode corrosion approx. theoretical.

The economy and efficiency of copper cyanide. C. H. PROCTER. *Foundry* 43, 199 (1915); see *C. A.* 9, 1151.

H. W. GILBERT.

Making the silver solutions. O. A. HILLMAN. *Metal Ind.* 13, 416–7 (1915).— $\text{KAg}(\text{CN})_2$ soln. contains 6 oz. KCN and 3 oz. Ag per gal., and is prepd. by using a warm strong soln. of KCN and a sheet Fe coil or brass cathode within a porous cup. The soln. is afterwards dild. to the proper strength. The cathode surface is equal to that of the anode. Anode hooks and cathode connections are large enough to carry the full amp. capacity of the dynamo to prevent overheating and undue resistance. The metal content is detd. by evapn. of 1 qt. to dryness, mixing the residue with an equal quantity of NH_4Cl and melting in a crucible. The Ag button should weigh 15 dwt. CS_2 dissolved in NaOH and KCN, NH_4HS , BaS or Sb_2S_3 prevents occlusion of H at the cathode and gives a hard and bright deposit. Peeling and spotting out are traced to improper cleaning or a poor "strike."

W. H. BOYNTON.

New form of electroplating barrel. ANON. *Iron Age* 96, 979(1915).—The equipment consists of a barrel suspended on top of a tank and a machine in which the nails, screws, rivets, or other material are washed, drained and dried. The barrel consists of a black rubber-like substance which has the tensile strength of metal and is non-absorbing. It has no moving parts immersed. The work is removed, when the plating is completed, by shifting the belt to a loose pulley. It is automatically emptied into the washing machine. The barrel is fed and the starting lever moved, which automatically closes the door. While the second batch is plated, the first is washed and dried. The washing and drying app. consist of 3 drums for washing, draining and drying, resp. The drying drum has a separate inner half perforated cylinder. The material mixes with sawdust and is carried to the second portion where the sawdust is sifted into the outer shell. One man can operate 3 or 4 barrels. W. H. B.

Supports for storage-battery cells. ANON. *Elec. World* 66, 1316(1915).—To the bottom of each cell case, along the longer sides, are attached 6-in. wood strips which transfer the wt. of the cell to the supports. The latter consist of conical shaped porcelain bases with glass caps containing oil rings. Between the bases and caps and between caps and cell cases crossed strips of Pb are placed, thus distributing the pressure uniformly over the surface of the glass and the porcelain. With 123-plate cells rated at 9150 amp. on the 1 hr. discharge rate 6 insulating supports are used. A cut is shown. I. C. MATTHEWS.

An arrangement to throw a battery out of circuit when charging current is interrupted. B. CAPRARO. *Elec. World* 66, 1317-8(1915).—An automatic device for throwing in the battery in the charging circuit when the generator starts and out again when it is shut down. The outfit operates with a current of from 2 to 14 amps. A diagram of wiring connections is shown. I. C. MATTHEWS.

Nickel-iron-alkaline cells for high-discharge-rate and submarine service. ANON. *Elec. World* 66, 1103-4(1915).—The compn. of the electrodes and the chem. reactions during battery charge and discharge are the same as in the case of the Ni-Fe alk. cells used on land. The batteries differ only in details of construction. The principle of the battery is the oxidation and reduction of metals in an electrolyte (KOH) which does not dissolve and will not combine with either the metals or their oxides. The following electrochem. action takes place in the cell. In first charge: $\text{Fe}_2\text{O}_3 + 6\text{K} + 3\text{H}_2\text{O} = 2\text{Fe} + 6\text{KOH}$ (negative); $3\text{Ni}(\text{OH})_2 + 6(\text{OH}) = 3\text{NiO}_2 + 6\text{H}_2\text{O}$ (positive). In discharge: $3\text{Fe} + 8(\text{OH}) = \text{Fe}_3\text{O}_4 + 4\text{H}_2\text{O}$ (negative); $6\text{NiO}_2 + 8\text{K} + 4\text{H}_2\text{O} = 2\text{Ni}_2\text{O}_4 + 8\text{KOH}$ (positive). In recharging: $\text{Fe}_3\text{O}_4 + 8\text{K} + 4\text{H}_2\text{O} = 3\text{Fe} + 8\text{KOH}$ (negative); $2\text{Ni}_2\text{O}_4 + 8(\text{OH}) = 6\text{NiO}_2 + 4\text{H}_2\text{O}$ (positive). The positive element consists of alternate layers of $\text{Ni}(\text{OH})_2$ and Ni flake inclosed in $\frac{3}{16}$ in. perforated steel tubes 4.5 in. long. Twenty of these clamped in a frame form a positive subgrid. The negative element is Fe_3O_4 mixed with a little Hg packed in flat, perforated, rectangular pockets $2\frac{3}{16} \times 1.2 \times \frac{1}{16}$ in. The negative subgrids contain 16 pockets. The main grids are made up of steel frames to which are welded the subgrids, the standard grids being 3 subgrids wide and 5 to 6 high. Each pair of subgrids (positive and negative) is rated at 15.6 watt hr. when discharged at 4.44 amp. to 1 v. The cells are compact, rugged and light in wt. and plates cannot be injured or short-circuited by jolts, vibrations or rolling and pitching on ships on which they may be installed. Cl cannot be generated within the cell even if immersed in sea water. Gas explosions cannot be communicated from the inside of the cell or *vice versa*. The same amp.-hr. rating is developed regardless of the rate at which the battery is discharged. Standing idle in charged, semi-charged or discharged condition will not injure the plates. Z. SMILOVICI.

Battery zincs: some causes of defective service. R. JOB AND F. F. WHITE. *Proc.*

Am. Soc. Testing Materials 15, II, 112-8(1915).—Serviceability depends upon the phys. condition of the Zn. Volatilization of Hg is minimized by avoiding overheating, and by keeping the molds cold. After the addition of Hg, the bath should be carefully stirred to avoid segregation. Results of tests are given. W. H. BOYNTON.

The electrolytic coating of mirrors. J. J. DECLÈRE, A. L. E. GRÉSY AND G. PASCALIS. *Electrician* 76, 19(1915); cf. *C. A.* 9, 398.—The fine Ag film of a mirror is protected by a lacquer or coating of Cu to prevent injury. The difficulties of making adequate contact with the very thin (0.0005 mm.) film of Ag are avoided by a new method in which the flat mirror is placed in a large flat plating bath upon a set of wood cleats. Contact with the surface of the Ag is made by a number of contact combs made up of a large number of brass teeth tipped with Sn to prevent scratching. These are insulated from the bath except at the extreme points and are of adjustable length. The position of the combs is changed every 10 min. Current at about 5 v. and a density of 30 amps. per sq. m. is supplied. The whole operation takes about 20 min. The electrolyte, an ammoniacal soln. of Cu, is kept circulating through a filter by a turbine pump. This prevents the settling of impurities upon the Ag surface. The washing is done in the same vat after the plating soln. is drained off.

W. E. RUDER.

Aluminium electrolytic lighting arrester for continuous currents. C. C. GARRARD. *Electrician* 76, 11-3(1915); cf. *C. A.* 9, 3033.—Mascicke condensers, the Giles valve and other lightning arresters are described. The best form for continuous current is the Al electrolytic cell. Diagrams of connections and of the internal construction of these are given, together with the methods and connections for earthing.

W. E. RUDER.

Behavior of half watt lamp on filling with nitrogen, to which small quantities of methane and carbon monoxide have been added. L. HAMBURGER. *Chem. Weekblad* 12, 62-73(1915).—H. investigated the effect of CO and CH₄ (which often occur in N gas) upon W filaments of N-filled lamps. It was found that when CH₄ was present, the largest amount of W carbide was formed in the cooler parts of the W wire (i. e., near the supports). The combination of W and C causes an increase in the resistance of the wire, renders it brittle and lowers its m. p. Small quantities of CH₄ (as low as 0.14%) were very injurious; a quantity of 0.09% of CH₄, however, did not produce any bad effects. The decompn. of CH₄ into C and H gives rise to another reaction: $(CN)_2 \rightleftharpoons 2C + N_2$. This reaction takes place to a certain extent at temps. as high as 3000°. It was furthermore found that HCN is formed by the presence of H, resulting from the decompn. of CH₄. CO, when present in an amt. higher than 2%, renders the W wire brittle; small amts. of CO showed little effect.

J. T. FLOHIL.

The A. E. G. nitra lamp. K. MGY. *Elektrotechn. Z.* 36, 376-7(1915), illus.—M. describes the elec. and photometric characteristics of the improved gas-filled W lamps.

Million-volt transformer demonstrated at the Panama-Pacific Exposition. NEILL WILLSON. *Elec. Rev. West. Elec.* 67, 945(1915).—This is a 1000-kw., 60-cycle transformer. The million-v. winding is made up of 190 5000-v. coils equally spaced and wound with flat Al (0.008 in. 0.1 amp.) conductor insulated by 3 layers of paper.

W. E. RUDER.

Electric strength of insulating materials under mechanical pressure. F. KOCK. *Electrician* 76, 6-8(1915); see *C. A.* 9, 1277.

C. G. F.

Primary electric battery. G. A. LUTZ. U. S., 1,161,322, Nov. 23. Structural features.

Galvanic battery. M. L. KAPLAN. U. S., 1,160,999, Nov. 16. Dense MnO_2 is deposited on particles of graphite by applying Mn nitrate soln., drying and heating to 170° and after removal of H_2O -sol. materials from the coated particles they are pressed into shape to form depolarizers for cells of the Leclanché type.

Electric dry battery. C. F. BURGESS. U. S., 1,162,449, Nov. 30. A depolarizing mixt. is used which is formed of graphite, at least a large % of which is finer than 200-mesh, mixed with MnO_2 , NH_4Cl , ZnCl_2 and H_2O .

Dry battery. I. KORETZKY. U. S., 1,160,907, Nov. 16. The depolarizing mass of the battery is formed of "recovered manganese" (the Mn ppt. produced as a by-product in making chloride of lime), mixed with C, moistened with NH_4Cl or ZnCl_2 , NH_4Cl and H_2SO_4 soln.

Secondary electric battery. J. O. LUTHY. U. S., 1,161,398, Nov. 23. An electrolyte containing 1% of AgCl dissolved in H_2O 60-70, Na silicate 4 and H_2SO_4 25-35% is used, mixed with PbO , PbO_2 and pumice used on Pb grids. The AgCl gives longer life and more uniform action to the battery.

Storage-battery cell structure. P. BROWN. U. S., 1,160,491, Nov. 16.

Storage-battery grid. W. S. HUTCHINSON. U. S., 1,159,035, Nov. 2. Structural features.

Apparatus for circulating the electrolyte in a series of storage battery cells. W. L. BLISS. U. S., 1,160,133, Nov. 16.

Storage-battery electrodes. E. HANDLER. U. S., 1,158,491, Nov. 2. Structural features.

Storage-battery electrodes. H. S. HAWKINS, A. M. GREEN and I. W. GIBBINS. U. S., 1,159,021, Nov. 2. The electrodes are formed of alternating superposed disks of volcanic scoria or other porous material and Pb oxide, centrally perforated and mounted on a supporting rod.

Electrolysis of alkali metal or alkaline earth metal chlorides. A. CLEMM. U. S., 1,160,847, Nov. 16. A diaphragm is used between the anode and cathode compartments, formed of a body portion, *b*, of BaSO_4 or other pulverulent material capable of resisting the action of the cell liquors, supported on the cathode side by asbestos fabric, *a*, or other material resistant to alkalis and on the anode side by plates, *c*, formed of material resistant to Cl and HCl, *e. g.*, glass, ebonite or stoneware.

Electrolytic production of sodium alloys. E. A. ASHCROFT. U. S., 1,161,585, Nov. 23. Alloys of Na with heavier metals such as Pb are produced by electrolysis of molten NaOH, using a cathode of the molten heavy metal at a temp. of about 400° while using a high c. d. at the anode and maintaining the electrolyte and cathode in motion during electrolysis.

Electrolytic apparatus for producing alkali metal amides, etc. E. A. ASHCROFT. U. S., 1,159,154, Nov. 2.

Electrolytic detinning. H. GOLDSCHMIDT. U. S., 1,160,400-1, Nov. 16. Several batches of tin scrap are placed in a series of metal receptacles in an alk. soln., *e. g.*, NaOH and Na stannate, and an elec. current of high amperage is passed in parallel through each batch of scrap and the receptacles and alk. bath. The electrolyte is heated to $70-80^\circ$ and circulated.

Incandescent tungsten lamp. F. SKAUPY. U. S., 1,160,661, Nov. 16. A small amt. of charcoal (or other porous material) containing Cl or other halogen is placed in the lamp bulb and the volatilization of the halogen compd. during the operation of the lamp serves to prevent blackening of the bulb by W. The amt. of the compd. used is so small that a good vacuum is maintained in the lamp.

Tungsten filament incandescent lamps. F. SKAUPY. U. S., 1,159,111, Nov. 2. A small amt. of TiCl_3 or other Ti-halogen compd. is placed in the lamp. In operation it does not materially lessen the vacuum and restricts the obscuration of the light caused by deposition of W on the glass bulb. $3\text{KCl} \cdot \text{TiCl}_3$, PtCl_4 , $3\text{KF} \cdot \text{HF} \cdot \text{PbF}_4$ and $3\text{KF} \cdot \text{PbF}_4$ act similarly.

Arc-lamp electrodes. G. M. LITTLE. U. S., 1,159,511, Nov. 9. The electrodes are formed of TiO_2 35, WO_3 5, Fe_2O_3 60, Cr_2O_3 4.5, H_3BO_3 6 and NaF 1 part. A temporary binder such as starch, glucose, oil or glycerol may be used if the mixt. is shaped by forcing through dies. Cf. C. A. 9, 2488.

Arc lamp electrode. E. J. WATZL. U. S., 1,161,173, Nov. 23. Fused oxides of Ti, W and Ce, La, Yb, or other rare earth metals, combined chemically in mol. proportions by heating to 2500° , are used with about 6 times their wt. of the usual body material, to form luminous arcs of high c. p. and intense whiteness.

Arc lamp electrodes. C. FIELD. U. S., 1,158,997, Nov. 2. Double fluorides of K or Na and Ce or Zr are added to electrodes formed of a usual good conducting mixt. to increase the temp. of the arc and give greater candle power.

Electric resistance furnace. A. DOW. U. S., 1,161,634, Nov. 23. The furnace has a granular C resistor.

Electric resistance furnace for heating crucibles, etc. P. A. BOZCK. U. S., 1,158,971-2, Nov. 2.

Electric furnaces for melting metals, etc. J. M. LOHR and H. W. GILBERT. U. S., 1,162,178-9, Nov. 30. (These pats. are "dedicated to the public," rendering them open to use by anyone in the U. S. without payment of royalty.)

Electric furnace for the manufacture of aluminium nitride. G. COUTAGNE. U. S., 1,158,899, Nov. 2. See Brit., 12,057 (C. A. 9, 2841).

Smelting zinc ores and other materials in an electric furnace. E. S. BERGLUND. U. S., 1,160,244, Nov. 16. After permitting the operation of smelting to proceed with an ordinary charge for some time, a mixed charge containing more readily fusible slag-forming constituents (*e. g.*, fluorspar) in addition to the usual constituents of the charge is added before tapping off the material to render the slag more fluid.

Reducing iron or other metals from ores. J. W. BECKMAN. U. S., 1,160,822, Nov. 16. The ore, *e. g.*, Fe_2O_3 , is heated to about 2000° or higher in an elec. furnace to liquefy it and a reducing gas obtained from cracking petroleum oil is forced through the highly heated material together with sufficient air to maintain the reaction temp. of the mixt.

Acetic acid. C. HANSEN and A. WEINDEL. U. S., 1,159,376, Nov. 9. C_2H_2 is oxidized on a Pt anode in an electrolyte of 30% H_2SO_4 containing about 1-2% of a Hg salt. The temp. of the electrolyte is maintained at $30-40^\circ$ and the electrolyzing cell has a porous clay diaphragm and a cathode of Pb or Cu (also immersed in 30% H_2SO_4). Cf. C. A. 9, 1095.

Protectors against electric currents of high potential. C. F. FRANK. U. S., 1,159,205, Nov. 2. A packing of 40-80 mesh carborundum granules is used between the electrodes, which serves to give equal static and dynamic breakdown voltage.

Electrolytic clarification of beer and other liquids. J. E. BLOOM. U. S., 1,162,213, Nov. 30. A large variety of liquids is listed which may be purified, clarified and prepared for storage without pptn. or formation of turbidity by passing over finely divided corundum or crushed quartz while warm and simultaneously subjecting them to the action of an a. c. The liquids which may be thus treated include beer, malt exts., brandy, whiskey, vinegar, milk, mineral water, coffee exts., pharmaceutical exts., colloidal solns. of dyes, turpentine oil, chemically hydrogenated oils, honey and molasses.

Electrolytic treatment of grape juice and wines. J. E. BLOOM. U. S., 1,162,212, Nov. 30. Grape juice or wine is passed rapidly through a mass of warm adsorption material such as corundum, crushed garnet or quartz, while acted on by an elec. a. c. to free it from suspended colloids and yield a product which will not become turbid or form a ppt. when stored and which is substantially free from deleterious micro-organisms.

Electrolytic apparatus. SCHOTT & GEN. Ger., 283,136, Nov. 11, 1913. The app. has a liquid anode and the cathode and anode are in direct contact through the solvent.

Ultraviolet rays. J. VON KOWALSKI. Ger., 284,091, Apr. 16, 1913. Ni, W, or their alloys with each other or with other metals, especially the rare earths, are employed as electrodes, and the metal vapor appearing in the arc gives rise to the ultraviolet rays. Cf. C. A. 9, 2741.

Arc for the production of ultraviolet rays. J. VON KOWALSKI. Ger., 284,979, Feb. 17, 1914. Addition to 284,091 (*supra*). One of the electrodes consists of a material (metal or alloy) unlike that of the other, so that the N oxides forming on one electrode are neutralized.

Electrodeposition of metals. T. R. HARRIS. Brit., 17,133, July 20, 1914. A printing roller, hydraulic ram, or like body is rotated at a peripheral speed of 200 ft. per min. in a plating vat. A current d. of 250 amp. per sq. ft. is employed. Parallel with the roller on both sides are the limbs of 1 or more U-shaped tubes, each having a row of slots or closely arranged perforations, or a continuous slot, through which electrolyte is squirted on to the roller by means of a pump. Flexible connections may be provided to allow of adjustment of the tubes. Perforations in the tubes on opposite sides of the roller are staggered.

Preparing surfaces for plating. L. HELLER. Brit., 16,690, July 13, 1914. Glass, porcelain, earthenware, terra-cotta, etc., are painted with a mixt. of about 5 parts of linseed oil, 5 of oil of turpentine, 250 of burnt bone-black, 180 of resin, and 420 of pure washed graphite. These ingredients may be mixed in a color mill. The painted objects may be baked at 80°, cooled, and polished by a rapidly rotating fiber brush, and are then plated, as with Cu or Ni.

Electrolysis. BADISCHE. Brit., 17,763, July 27, 1914. In obtaining alkali metals from molten alkali hydroxides, evolution of H at the cathode is prevented by supplying fresh anhydrous alkali in place of that which has taken up H₂O at the anode. The alkali removed may be dehydrated and re-used.

Obtaining alkalies and chlorine. SIEMENS & HALSKE AKT.-GES. Brit., 17,089, July 18, 1914. The rate of flow of a soln. of an alkali metal halide downward through an horizontal diaphragm is regulated by maintaining the Cl in the anode compartment above the diaphragm at a reduced pressure, so that the hydrostatic pressure on the diaphragm is partly counteracted. A suction pump with an adjustable regulator is provided for this purpose.

Selenium cells. N. S. YAPOLSKY. Brit., 17,131, July 20, 1914. A Se cell is

made by immersing a mold, comprizing bridges, with linear teeth, into liquid or plastic Se under diminished pressure, and cooling the Se under increased pressure, after which the base of the mold uniting the bridges is removed either mechanically or chem.

Vacuum tubes. A. LEDERER. Brit., 17,036, July 17, 1914. A lamp for low elec. pressures contains a gas or mixt. of gases, such as Ne, He, A or Kr, and a small quantity of 1 or more alkali metals, not forming the electrodes, which may be of Al, Mg, or W. The alkali metal or an alloy may be placed in a small pocket communicating with the lamp, and heated to cause it to deposit within the lamp, preferably near the electrodes only, the pocket being then sealed off. The alkali metal or alloy may alternately be in liquid or gaseous form within the lamp; a mere trace is usually sufficient.

Separating suspended bodies from fluids. E. MÖLLER. Brit., 17,175, July 20, 1914. The elec. separation of suspended bodies from insulating fluids, especially air or other gases, is effected by charging the ionizing electrodes with electricity of that sign which allows of the use of a higher potential difference before disruptive or luminous discharges take place, so that a more intense charging of the suspended bodies may be effected. In the case of air, the ionizing electrodes are charged with negative electricity.

Double diaphragm for continuous electrolysis of a flowing electrolyte. BAYER & Co. Ger., 284,937, July 24, 1913. The diaphragms are so constructed that the slime particles pass through small openings, while the products of one electrode chamber are not allowed to diffuse over into the other chamber.

5. PHOTOGRAPHY.

LOUIS DERR.

Contributions of the chemist to the photographic industry. FRANCIS C. FRARY. *J. Ind. Eng. Chem.* 7, 938-9(1915).—A part of the symposium at the Seattle meeting of the Am. Chem. Soc. E. H.

Color-sensitive plates for spectrum photography in the infra-red, red, yellow and green. J. M. EDER. *Phot. Korr.* 52, 271-7(1915).—Transmission curves and photographs of the solar spectrum are given for plates sensitized with dicyanin, dicyanin A, pinachrome blue and pinachrome violet, pinacyanol, pinacyanol blue, pinachrome, orthochrome and pinaverdol. For infra-red, dicyanin and dicyanin A are best. From infra-red to beyond yellow, pinachrome blue is recommended, NH_4OH increasing the sensitiveness. For yellow and green in addition to blue and violet, pinaverdol is best. With these dyes the entire visible spectrum may be photographed without difficulty. The plates used were bathed 4 min. in a bath of 200 cc. water, 100 cc. alc., 6 cc. 1:1000 alc. soln. of the dye, then quickly dried in total darkness. L. DERR.

Reduction of sensitiveness by amidol. H. LÜPPO-CRAMER. *Phot. Korr.* 62, 76-81(1915).—Plates bathed in 0.02% acid amidol, washed, dried, exposed, and developed by NH_3 vapors, show a greatly reduced sensitiveness as compared with the untreated plates. This is considered proof that as a result of halogen absorption the pulverization of AgBr by light is much hindered. Photomicrographs show the grain of the original plates to be much larger than that of the treated plates. "Grainless" emulsions of the Lippmann type show an interesting diminution of deposit on the slightly illuminated portions of the plate and an increase of deposit on the more strongly illuminated areas. L. DERR.

Removal of photographic developing and fixing agents from films and prints. C. A. BRAUTLECHT. *J. Ind. Eng. Chem.* 7, 899(1915).—To avoid waste of time and

water, it is recommended that plates, films and prints, when removed from the fixing bath, be put into running water and transferred every 2-3 min. to clean trays of running water. After removal of the prints, the last wash water is tested in a white tray by adding a few drops of 5% AgNO_3 . Any visible yellowish brown coloration shows insufficient washing. L. DERR.

Solarization of silver chloride. H. LÜPPO-CRAMER. *Phot. Kor.* 62, 281-2 (1915).—Evidence of the fact has hitherto been conflicting. The author has, however, been able to prepare an emulsion which shows it well; the emulsion, however, is not suitable for practical uses, as the image is thin and veiled. L. DERR.

Photomechanical printing surfaces. E. ROSENBERG. *Brit.*, 26,140, Nov. 14, 1913. The sensitive colloid layer which is to form the printing surface is supported on a rigid absorbent mass such as a fire-clay plate. After exposure and development, the plate is immersed in a bath of glycerol and H_2O . The absorbent support serves as a moisture container and maintains the colloid layer in a suitably moist condition. The printing ink used contains a colloid tanning agent, such as alum or HgCl_2 . A screen image and the pictorial image may be produced upon the colloid layer as follows: The picture pellicle of the negative is stripped from its support, reversed, and transferred to the front side of a gelatin film, on the back of which a screen has been printed. This film is copied as a negative on the colloid layer.

Color photography. F. E. IVES. U. S., 1,160,288, Nov. 16. A multi-colored print is prepd., from a set of color-selection negatives, on gelatin-coated paper by color impressions from gelatin reliefs made from the different color-selection negatives.

Photographic or cinematographic film. L. GAUMONT. U. S., 1,159,924, Nov. 9. The film is formed mainly of viscose with a very thin coating of sensitized collodion. The thinness of the coating permits developing, washing and fixing to be carried on so rapidly that the viscose is not materially affected by the H_2O in the solns.

Photographic or moving picture films. W. A. BEATTY. U. S., 1,158,963, Nov. 2. Films formed of a mixt. of cellulose acetate and a condensation product of acetone and PhOH are coated with a condensation product of acetone and PhOH with CH_2O applied in alc. soln., to protect the film from sparks, etc.

Cinematograph picture films. J. E. THORNTON. *Brit.*, 16,899, July 16, 1914. Cinematograph picture films are made by the dichromated colloid process in monochrome or colors as follows: From an ordinary positive film having continuous tones, a printing film with broken tones is obtained by reproduction through a half-tone screen. From this screen printing film, a print is made on to a C or other dichromated colloid film. The film is printed right through to the base and developed from the front. To obtain color films, sep. screen printing films representing component colors may be made from sep. color negatives or from an autochrome or other screen negative, and the positive film is resensitized and printed successively from these printing films. In producing the screen printing film, the position of the screen may be altered for successive exposures, so that the dots of successive pictures may come in a different place on the screen, thereby avoiding any grainy appearance.

Color filters. H. HARTRIDGE. *Brit.*, 17,789, July 27, 1914. A safe-light for photographic purposes which has the characteristic visual properties of white light. A filter is used which transmits 2 or more spectral areas, each of which is photographically safe, while combined they give visually white light. A superposed combination of gelatin filters colored with malachite green and picric acid is one example of a filter

transmitting portions of the spectrum corresponding substantially to λ_{730} — λ_{685} in the red, and λ_{540} — λ_{515} in the green. Other examples are given, and in all cases it is necessary that light of substantially shorter wave length than λ_{580} shall be transmitted. In a modified form, two or more independent sources of colored light are used, and in a further modification, a filter with colored strips or a mosaic of color areas. For color-sensitive or panchromatic plates, additional absorption filters must be used to cut out injurious rays, unless the developer is dyed or the color sensitiveness of the plate is destroyed before developing.

6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

Occurrences in the reactions of gases with silver and lead. W. STAHL. *Chem. Ztg.* 39, 885-6(1915).—A brief summary of observed facts in regard to the behavior of solid and molten Ag and Pb in the presence of O, H, N, SO₂, CO₂, CO and hydrocarbons, and also of Ag with A and He. A short bibliography is given.

J. H. MOORE.

The supposed tin-sulfur compound, Sn₂S. F. FICHTER. *Basel. Chem. Ztg.* 39, 833(1915).—F. considers the substance described by G. Epprecht (*C. A.* 9, 2357) to be a mixt. of SnS and metallic Sn.

J. H. MOORE.

7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

Report on testing chemical reagents. J. B. RATHER (Referee). *J. Assoc. Official Agr. Chem.* 1, 317-29(1915).—The purity and strength of crude NaOH, molybdic acid, com. citric acid, and ethyl ether have been studied in regard to their suitability for the detn. of N, phosphoric acid, insol. phosphoric acid, and ether ext., resp. (I). Four methods were used for the detn. of carbonate in crude NaOH. (1) Krauch-Merck, (2) Sutton, (3) Sutton, by pptn. as BaCl₂ and (4) the following modification by the referee: Dissolve 2 g. crude NaOH in H₂O and titrate with approx. 2 N HCl and phenolph. until the color fades. To another 2 g. portion add 0.5 cc. less of the 2 N acid, and titrate with 0.2 N acid until the color fades; read the buret, add 2 or 3 drops Me orange, and titrate until the color changes. The number of cc. 0.2 N acid required to change the Me orange $\times 1.06$ gives the % Na₂CO₃. All samples tested but 1 contained more than 90% NaOH. Methods (1) and (2) give discordant results both from duplicate detns. and by the 2 methods. Further study of method (4) and of the amt. of Na₂CO₃ which causes frothing in the N detns. is desirable before a limit is set. (II) Conditions affecting the detn. of N in NaOH. (A) Effect of the amt. of NaOH on the apparent N. Two methods were used: (1) Put 100 g. NaOH into a Kjeldahl flask with a little granulated Zn and distil into a receiver containing 5 cc. 0.2 N HCl. Titrate the excess acid with 0.1 N NH₄OH and cochineal. (2) Same as 1) except that 40 g. NaOH are used. Method (1) gives too high results as some of the NaOH is carried over mechanically. (B) Effect of the addition of H₂SO₄ on the apparent N. H₂SO₄ had no effect on the results when 40 g. NaOH were used and its use is therefore unnecessary. (C) Effect of redistn. of distillate on the apparent N. Differences in results were small and within the limits of error, but this point should be studied further. (III) Molybdic acid. (A) Methods for detn.: (1) Krauch-Merck, (2) referee's modification of (1). Dissolve 0.5 g. molybdic acid (H₂MoO₄)? in 50 cc. H₂O and 1 cc. NH₄OH, heat gently, filter if necessary, acidulate with 5 cc. HOAc, dil.

with 200 cc. H_2O , heat to boiling and add a filtered soln. of 1.5 g. lead acetate in 20 cc. H_2O . Boil several min., stirring constantly, allow to settle a minute or 2 and decant through a Gooch crucible. Wash by decantation 10 times, using 50 cc. boiling H_2O each time, allowing about a min. to settle. Transfer the ppt. to the gooch, ignite, cool and weigh the ignited ppt. as $PbMoO_4$. The factor 78.494 gives % MoO_3 . (3) Reference. A volumetric method was tried but not found suitable. Method (2) is much to be preferred over method (1), as it is much quicker (2 hrs. against 2 days). It is to be noted that "molybdic acid" in the official method probably means H_2MoO_4 (85%), but that nearly half of the coöperators seem to be using MoO_3 . (B) Phosphoric acid in molybdic acid. Total phosphoric acid, phosphoric acid in the official soln. and sulfates were detd. In only 2 cases was even a slight amt. of phosphoric acid found; hence it appears that errors from this source are insignificant. No sulfates were found, but the effect of the sulfates should be studied further. (IV) Citric acid. The samples of citric acid were tested for ash, for oxalic, tartaric, and sulfuric acids, and for sugars. It appears that the purity of the samples of citric acid is quite sufficient for fertilizer control work. The subject should be studied further. (V) Ethyl ether. Four samples were examd. for matter non-volatile at 100° . Evap. 100 cc. in a tared Pt dish to dryness over a steam bath. Dry at 100° to constant wt. The amt. of non-volatile matter may introduce errors as high as 1.5%. The method used, together with the question of the presence of alc. and H_2O and other possible impurities, should be studied further.

F. A. HARVEY.

The effect of ammonium chloride upon ferric and aluminium hydroxides during ignition. H. W. DAUDT. *J. Ind. Eng. Chem.* 7, 847(1915).—When $Fe(OH)_3$ and $Al(OH)_3$ are ignited in the presence of small amts. of NH_4Cl no loss occurs as a result of the formation and volatilization of the metallic chlorides. The washing of $Fe(OH)_3$ with a 1% soln. of NH_4Cl before ignition does not cause any loss, but when the soln. contains as high as 5% NH_4Cl a small loss occurs. The use of a 10% soln. causes a decided loss. $Al(OH)_3$ can be washed with a 5% soln. without loss of Al. D. describes in detail the manipulation, by means of which a rapid filtration and washing of $Al(OH)_3$ was obtained.

H. W. D.

The electrolytic assay of lead. E. A. LEWIS. *Metal Ind.* 13, 463(1915).—*Cartridge metal and rolled brasses:* Dissolve 5 g. in 40 cc. HNO_3 (1:1), boil off nitrous fumes, dil. to 150 cc. with warm H_2O , electrolyze with a current of 3 amp. for 25 mins., using a rotating electrode, wash off cover, and continue for 5 mins. more. Wash and dry anode as usual; if Pb is low 10 mins. drying at 200° suffices, and the factor is 0.866; with over 20% Pb the factor is 0.865. With brasses low in Pb, the soln. for electrolysis must not be above 40° ; with cartridge metals containing 0.03%, or less of Pb, dissolve 10 g. in 80 cc. HNO_3 (1:1), dil. to 200 cc. and electrolyze. *Gun metals:* Treat 5 g. with 30 cc. concd. HNO_3 and 15 cc. H_2O , digest as above, dil. with hot H_2O , let settle, filter off Sn ppt., and electrolyze as above. The Sn does not carry down Pb to any serious extent, but contains Sb, P, As, Fe and a little Cu. It is unnecessary to evap. the soln. to pastiness or dryness before filtering. *White metals:* When low in Sn, follow method for gun metal; with solders and rich Sn alloys filter off the Sn ppt. from the HNO_3 treatment and digest with $(NH_4)_2S$ soln.; filter off any PbS , digest the ppt. with 15 cc. concd. HNO_3 to form $PbSO_4$, add hot H_2O , boil, cool, det. the small amt. of Pb by electrolysis, and add to the Pb obtained on electrolyzing the first filtrate. *Spelter:* Treat 5 or 10 g., according to the Pb content, with 40 or 80 cc. HNO_3 (1:1), adding the acid cautiously, 1 or 2 cc. at a time; expel nitrous fumes, dil. to 150 or 200 cc., filter off Sn if present, and electrolyze; with very high grade spelter, the temp. must not exceed 40° . For more accurate work, treat 20 g. with a mixt. of 40 cc. concd. H_2SO_4 and 200 cc. H_2O , keeping the soln. cool during the process, until the bulk of the Zn is

dissolved, filter off the Pb and dissolve it in 15 cc. HNO_3 , dil. to 150 cc., filter off Sn, if present, add 5 cc. HNO_3 , and electrolyze. *Ores and residues:* Grind to pass through a 60-mesh sieve, sepg. fires and metallics in the case of residue. Digest 1 g. of a sulfide ore or a sulfate residue with 30 cc. concd. HNO_3 , until all the sulfide is converted into sulfate, boil off the nitrous fumes, add about 100 cc. of hot H_2O and heat until the PbSO_4 dissolves; then electrolyze with 3 amp. for 30 mins., without filtering off any residue. If very little residue is present, the anode can be weighed after drying at 200° in the usual way; with much residue, dissolve the deposit on the anode in HNO_3 (1:3), adding a little oxalic acid; dil., filter if necessary, add 10 cc. HNO_3 , dil. to 150 cc., electrolyze again, and weigh the PbO_2 . F. W. SMITHER.

Analysis of turbadium bronze. H. WILLIAMS. *Chem. News* 112, 175-6(1915).—Turbadium bronze contains approx. Cu 48, Zn 46.45, Sn 0.5, Pb 0.1, Fe 1.0, Al 0.2, Mn 1.75, and Ni 2.0%; it has a tensile strength of 35-42 tons per sq. in., and an elongation (on 2-in. test piece) of 14-20%. It is used for making solid propeller castings, not being appreciably corroded by sea-water. *Tin:* Heat 1 g. of the drillings with 20 cc. of HNO_3 (d. 1.2), evap. to about 10 cc., add 50 cc. of H_2O , let insol. matter settle, filter, wash with 5% HNO_3 , ignite in a porcelain crucible, cool, and weigh SnO_2 . *Copper:* Electrolyze filtrate and washings (not over 100 cc.) from the SnO_2 with a current of N. D.₁₀₀ = 1 amp. and 2.5 v., using Pt gauze electrodes with a rotating anode; wash, dry, and weigh as usual. *Lead:* Dissolve PbO_2 deposited on anode in a mixt. of 5 cc. concd. HNO_3 , 10 cc. H_2O , and 4 drops of alc., remove, and wash anode, add 3 cc. concd. H_2SO_4 , evap. to fumes, cool, add 30 cc. of H_2O , filter on a gooch, wash with 2% H_2SO_4 , remove filtrate, then wash with alc., dry, and weigh as PbSO_4 . *Iron and aluminium:* Evap. the soln. and washings from the Cu and Pb detns. to about 30 cc., add 5 g. of NH_4Cl , ppt. the hydroxides of Al, Fe, and Mn by the addition of 30 cc. of satd. Br water and 30 cc. concd. NH_4OH ; boil, let settle, filter, and wash. Dissolve ppt. (using beaker in which pptn. was made) in hot dil. HCl and H_2SO_4 , boil to expel SO_3 and oxidize Fe^{2+} with a few drops of HNO_3 ; sep. the Mn from the Al and Fe by the basic acetate process, ignite, and weigh the ppt. of $\text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$; dissolve in 20 cc. concd. HCl, reduce with SnCl_2 , add HgCl_2 , and titrate with $\text{K}_2\text{Cr}_2\text{O}_7$ for Fe, obtaining Al by difference. *Manganese:* Treat separately the filtrates from the PbSO_4 and the basic acetate pptn. with Br water and NH_4OH , collect the ppts. on the same filter, wash with hot H_2O , ignite, and weigh as Mn_2O_4 . *Zinc:* Evap. the filtrate and washings from the first pptn. of Al, Fe, and Mn to about 150 cc., add AcOH till neutral to litmus paper, and then 1 cc. excess; add 4 g. of $(\text{NH}_4)_2\text{HPO}_4$ in usual manner, filter, redissolve the NH_4ZnPO_4 in dil. HCl and reppt., using 2 g. of precipitant, let settle, filter on gooch, wash with hot H_2O , ignite, and weigh as $\text{Zn}_2\text{P}_2\text{O}_7$. *Nickel:* Render the combined filtrates and washings from the Zn ppt. slightly alk. with NH_4OH , heat to 70° , and det. the Ni by the dimethylglyoxime method. The alloy usually contains 0.1% of impurities (Bi 0.03, As 0.05, O as $\text{Cu}_2\text{O} + \text{CuO}$ 0.02%), and the percentage of Zn may be obtained with sufficient accuracy by subtracting the sum of the other constituents from 99.9% (detg. the Ni in the presence of the Zn). W. gives notes on the various operations. F. W. SMITHER.

The determination of methyl alcohol by Rinck. G. FENDLER. *Z. Nahr.-Genussm.* 30, 228-30 (1915).—A criticism of Rinck's method (*C. A.* 9, 123). Rinck's method will give tests for MeOH in alc. which is free from MeOH.

HELEN N. ELLIOTT.

Modification of the Mohler reaction of benzoic acid (GROSSFELD) 12. Determination of phytosterol (WAGNER) 12.

8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY.

The solubility of calcite in water in contact with the atmosphere and its variation with temperature. R. C. WELLS. *J. Wash. Acad.* 5, 617-22(1915).—W. performed expts. designed especially to show the effect of temp. on the solubility of calcite. The method of working consisted in agitating the solns. under investigation by a current of outdoor air for long intervals. The Jena flasks employed were kept in a thermostat while air was being passed and for the expts. at 1° C. they were continuously immersed in a mixt. of ice and water in a refrigerator. The air used for stirring was filtered through cotton and washed with water. The Joplin calcite used had the following compn.: SiO_2 0.09, MnO 0.05, FeO 0.19, CaO 55.8, MgO none, CO_2 (diff.) 43.87%. The Ca content of the solns. was calcd. from the result of titrating about 50 cc. with 0.02 *N* NaHSO_4 , using methyl orange as indicator. Tables are given and a curve shown of the results obtained. The geochemical conclusion to be drawn from the results is that in solns. freely exposed to the atm., solid CaCO_3 is considerably more sol. at low temps. than at higher temps. Two applications of these data to results in nature are mentioned. The Mississippi River flows in a direction of rizing temp., and results of analysis show the dependence of the solubility of CaCO_3 on its temp. Another application may be found in the formation of marble from coral. J. H. BOWER.

Chemical composition of bornite. EDGAR T. WHERRY. U. S. Nat. Museum. *Science* 42, 570-1(1915).—Attention is called to certain points which it is thought were not sufficiently emphasized in the paper on this subject by Rogers (*C. A.* 9, 2858), and it is suggested "that the variability in the compn. of bornite (normally Cu_5FeS_4) is due to the presence of submicroscopic inclusions of one or more of the minerals often occurring as visible inclusions in it, namely, chalcocite, chalcopyrite and pyrite." L. W. RIGGS.

Notes on allophanite, fuchsite, and triphylite. EDGAR T. WHERRY. *Proc. U. S. Nat. Museum* 49, 463-7(1915).—It is recommended that the various colloidal hydrous Al silicates be all grouped into 3 species, the one with the ratio $\text{Al}_2\text{O}_3 : \text{SiO}_2$ from 1:1.5 to 1:0.25, being named allophanite. Stremme (*Doelter's Handb. Min. Chem.* 2, Pt. 2, 36(1914)) has shown that the evidence indicates such noncryst. clay minerals to be adsorption compds. of colloidal Al_2O_3 and SiO_2 with variable amts. of H_2O . A new occurrence of this mineral has been found near Salt Lake City, showing H 3, sp. gr. 1.88-1.90; isotropic (amorphous, colloidal) in large part, also showing confusedly anisotropic (metacoloidal) patches. The n varies with the H_2O content, from 1.465 with about 45% to 1.595 in the dehydrated material, being the average of the n s of the constituents in each case; this confirms Stremme's conclusion or at least indicates that no complete chem. combination is represented. Analysis of microscopically homogeneous, amorphous, material gave Al_2O_3 33.78, Fe_2O_3 1.08, SiO_2 21.70, CaO 2.04, MgO 0.45, H_2O below 100° 4.86, H_2O above 100° 35.82, sum 99.73. The name fuchsite is used to refer to the isomorphous series of which $\text{H}_2\text{K}(\text{AlSiO}_4)_2$ and $\text{H}_2\text{K}(\text{CrSiO}_4)_2$ are the end members, the first being usually present in excess over the second. Occurrences are reported from West Bradford, Chester Co. Pa., and the marble quarries of Colo., which contain 3.0 and 6.08% Cr_2O_3 , respectively. A new occurrence of triphylite has been discovered near Grafton, N. H. Analysis by J. E. Whitfield gave FeO 27.66, MnO 16.63, MgO 2.30, Li_2O 8.40, Na_2O 0.35, K_2O 0.00, P_2O_5 43.85, SiO_2 0.27, H_2O 0.41, sum 100.02. Sp. gr. 3.531; α 1.690, β 1.690, γ 1.695. This is close to the compns. of material from the old Grafton locality and from Norwich, Conn. In accordance with W.'s plans for simplifying mineralogical nomenclature this mineral is described as a triphylite containing 60% lithio-ferro-triphylite, 37%

lithio-mangano-triphyllite, and small amts. of several other members of the series.

L. W. RIGGS.

Lode deposits of the Allegheny district, California. H. G. FERGUSON. U. S. Geol. Survey, *Bull.* 580-I, 153-82(1915).—In the southwestern part of Sierra Co., Cal., Au is found in quartz veins associated with arsenopyrite. The milky whiteness of the quartz is due to reflection from the surfaces of innumerable cavities not greater than 0.01 mm. in diameter and usually much less. Some of these cavities contain liquid as well as gas. From the position of certain fragments of arsenopyrite, F. concludes that the quartz was formed after the arsenopyrite. After a period of crushing, Au and PbS were deposited. The Au is chiefly found near the arsenopyrite. The formation of the ore shoots therefore depended on at least two sets of conditions: (1) the formation of coarsely cryst. arsenopyrite, and (2) the accession of solns. bearing Au. (1) seems to have occurred where lenticular swellings in the original vein gave max. opportunity for circulation of the silica-bearing soln., from which the arsenopyrite must have crystd.

R. C. WELLS.

The disseminated copper ores of Bingham Canyon, Utah. J. J. BRESON. *Bull. Am. Inst. Mining Eng.* 1915, 2191-236.—The first part of this paper (to be read in February, 1916) deals with the country rock, its pegmatitic, pneumatolytic, and hydrothermal alterations; also the effect of magnetite on the deposition of the primary chalcopyrite and pyrite. The second part of the paper includes a detailed account of the processes of secondary enrichment which have been effective in producing the disseminated ores. Numerous plates are shown. The conclusions as to the formation of the important sulfides in the disseminated ores are as follows: Pyrite, chalcopyrite, and probably a minor amount of bornite are the primary Cu minerals. The primary sulfides do not occur in these ores as magmatic sulfides, but owe their present distribution to the magnetite, which was magmatic. Covellite is the most abundant secondary Cu mineral forming by a replacement of chalcopyrite in slightly acid to neutral solns. Chalcocite is the most important secondary Cu mineral formed under slightly acid to alk. conditions. Secondary chalcopyrite may be an intermediate mineral between pyrite and chalcocite; and bornite may be formed as an intermediate product between chalcopyrite and chalcocite. Secondary chalcopyrite and bornite may also be formed by the replacement of the Cu in chalcocite or covellite by the Fe of the FeSO_4 . The concn. of the FeSO_4 in the secondary solns. is probably an important factor in secondary enrichment.

J. H. BOWER.

Iron ore on Calambayanga Island, Mambulao, Carmarines. W. E. PRATT. *Philippine J. Sci.* 10A, 323-31(1915).—The ore body is irregular in shape. It consists of magnetite and hematite and carries fresh quartz and pyrite. The main portion is almost pure massive or granular hematite, soft and very porous. Av. ore carries 60% Fe and is free from objectionable impurities, being below the Bessemer P limit. The amt. of ore is undetermined, but it appears to exist in commercial quantities.

H. C. BERMAN.

Iron ore in Surigao Province. W. E. PRATT AND V. E. LEDNICKY. *Philippine J. Sci.* 10A, 335-46(1915).—The ore body is ferruginous clay and is composed of a series of hydrous Fe oxides related to limonite. The color at the surface is red-brown, beneath the ground yellowish brown. The ore is 20 m. thick and is soft and spongy or mealy. Analysis shows about 52.5% Fe in dried ore. Estimate is 275,000,000 metric tons good ore and 222,000,000 metric tons poor ore (in regard to the accessibility and nature of deposit). The ore is free from S and P, and gives promise of future importance.

H. C. BERMAN.

Recent alunite developments near Marysvale and Beaver, Utah. G. F. LOUGHLIN. U. S. Geol. Survey, *Bull.* 620-K, 237-70(1915).— K_2SO_4 is now being manufactured

from alunite. The deposits of alunite thus far found are veins cutting porphyry. In some places bands of quartz alternate with bands of alunite. Three varieties of alunite have been noted: coarsely crystalline, which is practically pure; fine-grained, which may be mixed with SiO_2 or kaolin and resembles kaolin; and laminated, the structure being due to shearing. L. describes various prospects and gives hints as to possible by-products in the utilization of alunite.

R. C. WELLS.

The phosphate deposits of Florida. G. C. MATSON. U. S. Geol. Survey, *Bull.* 604, 100 pp. (1915).—The geology of the deposits, analyses of the several kinds of phosphate, and discussions of their mode of origin are given.

R. C. WELLS.

A new phosphatic ore. B. DE ROLLIERE. *Chem. Trade J.* 57, 365 (1915).—R. claims the discovery in France of a considerable deposit of a new variety of ore extremely rich in P, the composition of which is given as: H_3PO_4 50.1, CaO 0.005, SiO_2 4.25, KOH none, Na_2CO_3 0.005, Fe none, free Al_2O_3 8.30, combined Al_2O_3 22.80, Mn none, F 4.15, combined H_2O 5.60, loss 4.79%.

J. H. BOWER.

Persistence of Philippine coal beds. W. E. PRATT. *Philippine J. Sci.* 10A, 289-99 (1915).—The beds are not of superior quality, black lignites and sub-bituminous coals predominating. These are subject to spontaneous combustion. The obstacle to successful exploitation is the discontinuity of the beds owing to faulting.

H. C. BERMAN.

Geologic reconnaissance of Mountain Province, Luzon, P. I. W. D. SMITH. *Philippine J. Sci.* 10A, 177-207 (1915).—A trip through northern Luzon is described. The geology and mineral deposits of the district are discussed, coal, clay, S, building stone, Au and Fe being found. Water power is available.

H. C. BERMAN.

Geologic reconnaissance in Caramoan Peninsula, Carmarines Province. W. E. PRATT. *Philippine J. Sci.* 10A, 303-19 (1915).—Small unimportant deposits of Au, Cu, Hg, coal, and clay were found.

H. C. BERMAN.

Petrographic analysis of the Bridger, Washakie, and other Eocene formations of the Rocky Mountains. ALBERT JOHANSEN. U. S. Geol. Survey. *Bull. Am. Mus. Nat. Hist.* 33, 209-22 (1914).—Many of the sediments were found to be composed of fragments of volcanic rocks, in part deposited directly as tuffs, and in part reworked by water. The general type seems to be that of dacite, or even quartz diorite, although the quartz may not have come from the same source as the feldspars and volcanic glass. Certain geologic correlations are made possible by such petrographic studies of the beds.

Petroleum and residual bitumens in Leyte, P. I. (PRATT) 22. Petroleum in Cebu, P. I. (PRATT) 22. Evaporation of potash brines (HICKS) 18.

9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

The production of iron and steel in Canada during 1914. JOHN McLEISH. Canada Dept. of Mines, Mines Branch, *Bull.* 349, 35 pp. (1915).

E. J. C.

Casting from blast furnace. J. E. JOHNSON, JR. *Iron Age* 96, 1054 (1915).—An outline of J.'s method based on the action of O. "The process may be practiced by various means and mechanisms, desirably by using an ordinary type of plant and blowing Fe taken directly from a blast furnace in a Bessemer converter at a low temp., so that the Si is nearly all burned out before any of the C burns, and stopping the blow when the C flame appears. This impregnates the bath with O and by mixing other

Fe direct from the furnace with the white Fe so produced, Si is restored without removing all the O," i. e., the Fe is converted from white back to gray. The process is briefly discussed. Cf. C. A. 8, 897. .

F. W. SMITHER.

Atomizing fuel oil. R. A. BULL. *Iron Age* 96, 1049-50(1915).—B. reports the results of an investigation, by the Committee on Steel Foundry Standards of the American Foundrymen's Association, into the relative advantages and disadvantages of atomizing fuel oil with steam and with air in basic open-hearth steel furnaces to determine which of the 2 agents is preferable from every standpoint, including cost, time, quality of product, etc., both in basic and in acid practice. It is concluded that there would be a considerable advantage in employing superheated steam as an atomizing agent in basic open-hearth practice, with no loss in the quality of the product.

F. W. SMITHER.

The prevention of hydrolysis in cyanide solutions. H. M. LESLIE. *J. Chem. Met. Soc. S. Africa* 16, 36-49(1915).—An exptl. study reported in detail. It is shown that: (1) Simple cyanide solns. decompose by the hydrolysis of the soln.; (2) the percentage loss by this reaction is greater in a given time, the weaker the soln.; (3) increased temp. accelerates this decompn.; (4) the alkali formed as a product of the hydrolytic action has little or no protective action on the remaining cyanide, so that hydrolysis goes on until all the cyanide is destroyed; (5) the protection afforded by the addition of an excess of caustic alkali is by no means complete and is only of a very temporary nature. Expts. with open (present method) and "closed" systems are described at some length, showing conclusively the enormous saving which can be effected by the introduction of the closed system for the treatment of ores by cyanide.

F. W. SMITHER.

Precipitation with zinc-thread. J. A. CARPENTER. *Mining Sci. Press* 3, 888-91 (1915).—C. gives data on pptn. with Zn-thread at a Tonopah mill showing that this method, although second in efficiency to the use of Zn dust, gives excellent results when operated under favorable conditions. The results show that the high cyanide and alkali strength of the pregnant soln. is responsible for the high Zn consumption in Ag cyanide plants. A greater vol. of Zn-box capacity for a given tonnage of soln. does not increase Zn consumption, but rather tends to decrease it by allowing ample space for the care of the short Zn. Working with a mill-soln. of 3 lbs. KCN and 0.7 lb. protective NaOH, the av. consumption of Zn in lbs. per oz. of refined bullion extd. for 6 months was 0.0453 lb., or 0.66 oz. troy.

F. W. SMITHER.

Zinc in the cyanide mill. A. DORFMANN. *Eng. Mining J.* 100, 680(1915).—Owing to the high price of Zn, due to the European war, and to the fact that a great deal more Zn is used than is theoretically required for pptn. of Au and Ag contained in soln., D. carried out a series of expts., at the McIntyre-Porcupine Mill in the Porcupine Au district of Ontario, in an effort to reduce the Zn consumption. The results are given in tables under the captions: Exptl. data on Zn in cyanide solns., analysis of solns. used in expts., consumption of Zn in various depts. While the work does not point toward a remedy for the difficulties encountered, it does show what is actually taking place in the mill.

F. W. SMITHER.

Cyanide consumption on the Witwatersrand. H. A. WHITE. *J. Chem. Met. Soc. S. Africa* 16, 24-36(1915).—Based on the amt. of cyanide purchased and the total tons of ore milled, and assuming no great increase in the stocks on hand, the av. consumption of cyanide in 1914 was 0.40 lb. per ton of ore treated, while Zn figured at 0.32 lb. The present paper gives in much detail the results of an exptl. study to ascertain exactly where all this goes (5,000 tons NaCN) and what are the possibilities of effecting any significant saving.

F. W. SMITHER.

Notes on the treatment of antimonial gold ores from the Murchison range. H. R. ADAM. *J. Chem. Met. Soc. S. Africa* 15, 322-7(1915).—The "reef," located in N. E. Transvaal, has been traced for over 40 miles. Satisfactory methods of treatment of the ore have not been found. The ores are classed as: (1) Partly oxidized (Sb over 2%); (2) partly oxidized (Sb under 2%); (3) sulfides (Sb over 2%); (4) sulfides (Sb under 2%). *Class 1.* Cyaniding extracts but 50% of the Au, with high cyanide consumption, a difficulty increased by use of CaO or alkali. Careful roasting, followed by cyanide, was good in lab. tests, but failed in practice. The ore can be worked for Sb. *Class 2.* Plate amalgamation, followed by concn. and cyaniding, gave an extn. of 70 to 80% Au. Pan amalgamation gives too much slime. *Class 3.* In general, the higher the Sb, the lower the Au. Various methods have been proposed. Mixing with charcoal, and roasting at below 400° to volatilize Sb₂O₃, worked fairly well in removing much Sb, but the residues were incompletely extd. by KCN. Strong HCl will dissolve the Sb₂S₃, which is precipitable on diln. Mixing with MgCl₂ and treating with superheated steam promised well, but the material frits too soon for good removal of Sb. The usual concn. method is unsatisfactory, because crushing stibnite gives too much slime. A detailed account is given of expts. on concn. by acid flotation. Much Sb goes into the froth; Au values go into the settled portion. *Class 4.* By concg., then grinding and cyaniding, extn. of 80% of the Au may be attained. F. J. Pooler suggested for Class 3 mixing with NaCl and driving off SbCl₃ by volatilization. H. Meyer mentioned the ore of the Cam and Motor mine in Rhodesia which is an arsenical pyrite contg. some Sb. Treatment is crushing in ball mills, roasting (mechanically), fine grinding with KCN and vacuum filtration; 75% extn. was attained (lab. expts. showed 85%). E. WALLER.

Zinc oxide from lead blast furnace slag. H. B. PULSIFER. *Met. Chem. Eng.* 13, 783-5(1915).—Zn is being recovered from a 150,000 ton Pb-refinery slag-dump in South Chicago by means of a remodeled Pb blast furnace, 46 X 156 in. at the tuyères, having a capacity of 65 tons daily. The slag carrying 12% Zn, charged with additional lime and coke, yields besides 7% Zn as fume, a ton of Ag-bearing Pb and speiss per day. The furnace is run with hot top on 12-oz. blast. The plant yields a considerable profit in spite of the low efficiencies of Zn recovery and fuel consumption.

H. L. OLIN.

Smelting at Panulcillo, Chile. ANON. *Eng. Mining J.* 100, 787-9(1915).—An account of the smelting operations of the Central Chili Copper Co. at Panulcillo in the province of Coquimbo. Besides the ore (sulfide) of its Panulcillo mine, the company smelts custom ores (carbonates and oxides), for which a bedding system is provided. About 7000 tons of ore are smelted per month with an av. slag analysis of SiO₂ 40.9, Fe 15.6, CaO 12.3, Al₂O₃ 22.8, MgO 1.1, Cu 0.43%. German coke was previously used; at present English coke is used. F. W. SMITHER.

Monometer tinning furnace. ANON. *Electrician* 76 (suppl.) 56-8(1915).—An account of a new process recently introduced by the Monometer Mfg. Co. (Ltd.), Birmingham, Eng. The special features comprize a complete enclosure of the melting pots, means for preventing oxidation of the molten metal, a self-acting heat controller for holding the metal at the correct fluidity, heating by low-pressure gas with intense heat and without fans, blowers, or compressors, special guiding, devices for threading the wire onto the rollers and for elimination of fumes. This process is cheaper and more efficient than other methods in use, and an enormous saving in residue is effected. Diagrams of the furnace are given. I. C. MATTHEWS.

Analysis of Turbadium bronze (WILLIAMS) 7. Electrical applications of aluminium (RICHARDS) 4.

Flotation apparatus for sulfide ores. L. G. ROWAND. U. S., 1,159,713, Nov. 9.

Apparatus for leaching ores. P. A. ROBBINS. U. S., 1,160,200, Nov. 16.

Apparatus for amalgamating ores. V. I. ZACHERT and P. A. BRANGIER. U. S., 1,160,485, Nov. 16.

Smelting ores. J. H. KLEPINGER, M. W. KREJCÍ and C. R. KUZELL. U. S., 1,160,621. Nov. 16. Oxides of Zn, Cu, Pb, or other oxide ore, flux and fuel are introduced into a reduction chamber while finely divided (in the form of a spray or dust) and the fuel ignited so that each particle of ore is entirely surrounded by reducing gas; the fused particles which settle are led to a settling chamber while kept under agitation and the metal and slag are allowed to separate.

Furnace for desulfurizing or calcining ore, etc. F. MEYER. U. S., 1,162,634, Nov. 30.

Furnaces for roasting ores. U. WEDGE. U. S., 1,162,532-3-4, Nov. 30.

Furnace for roasting ores. U. WEDGE. U. S., 1,159,141, Nov. 2.

Cyanide extraction of ores. H. M. LESLIE. U. S., 1,158,513-4, Nov. 2. The pat. relates to the method of handling the soln. and circulating it in a closed system.

Apparatus for agitating ore pulp with cyanide solutions. H. R. CONKLIN. U. S., 1,160,848, Nov. 16.

Precipitating metals from cyanide solutions. H. R. CONKLIN. U. S., 1,160,849-50, Nov. 16. A solid pptg. material, such as Zn or Al balls 29, is introduced into the upper end of the pipe 1 and passes through it to the lower turn of the worm pipe 7 and by slow rotation of the latter is carried to the upper end of the pipe 7 and discharged onto the rib 9 in the chamber 8 and finally is fed back into the pipe 1 by the short spiral pipe 10. Soln. to be pptd. is supplied continuously through the pipe N and passes through the conduits 26, 28, 8, 7 and 25 into the tank T. The balls are gradually dissolved and their residual particles are carried with the soln.

Sulfatizing of organic compounds or ores of copper and other metals. H. B. HOVLAND and G. B. FRANKFORTER. U. S., 1,159,032, Nov. 2. Ores are sulfatized by treatment with O and SO₂ under pressure while subjected to the action of an elec. arc. Org. compds., e. g., alc., may also be sulfatized with O and SO₂ under pressure. The elec. arc hastens the process by generation of N oxides.

Sulfatizing ores. H. B. HOVLAND and G. B. FRANKFORTER. U. S., 1,159,033, Nov. 2. The ore in the form of a pulp is treated with O and SO₂ under pressure at ordinary atm. temp. The reaction may be hastened by subjecting the materials to the action of N oxides (produced by action of an elec. arc) or by NaCl.

Obtaining copper or other metals from ores. H. B. HOVLAND. U. S., 1,159,942, Nov. 9. Ores of Cu or other oxidized ores are treated with H₂SO₄ to dissolve the metal and the soln. obtained is treated with CaS and Fe₂(SO₄)₃ to ppt. the metal as sulfide.

Extracting copper from ores and gangs. E. ERDOS. U. S., 1,162,044, Nov. 30. The disintegrated roasted material is treated with a soln. of Al₂(SO₄)₃ which is regenerated by the addition of H₂SO₄ after the formation of basic Cu and Al salts. On concg. the soln. CuSO₄·5H₂O crystallizes and CuSO₄·Al₂(SO₄)₃·14H₂O is held in soln.

Obtaining iron, gold, silver and other metals from ores and smelter residues. A. ESTELLE. U. S., 1,162,150, Nov. 30. The material is leached with HCl, Fe is deposited electrolytically from the ferrous soln. thus formed, using insol. anodes, and the insol. sulfides of other metals remaining in the leaching app. are treated with solvents or otherwise recovered. The H_2S from the leaching is washed with ferric soln. from the electrolysis and the acid soln. formed after sepn. from S is used in the leaching.

Removing cadmium from zinc ore. G. RIGG. U. S., 1,161,885, Nov. 30. Roasted or naturally oxidized Zn ore is heated to $700-850^\circ$ and treated with a reducing gas flame in which the reducing gas is largely in excess, additional air being admitted intermittently only as necessary to maintain the temp. until the Cd is driven off from the ore.

Removing cadmium from zinc ore. G. RIGG. U. S., 1,161,886, Nov. 30. A layer of Zn ore containing Cd, either roasted or naturally oxidized, is covered with a layer of fuel which is ignited and air is passed downward through the fuel and ore in an amt. regulated so as to maintain the temp. above the point of volatilization of Cd but below the volatilization temp. of Zn at the zone of exit of the gases from the charge.

Detinning tin-scrap. H. FOERSTERLING and H. PHILIPP. U. S., 1,160,590, Nov. 16. The Sn on the scrap is alloyed with Na by treatment with molten Na in a countercurrent process until an alloy containing about 50% of Sn is obtained.

Producing aluminium from its silicates. G. MËLLEN. U. S., 1,160,431, Nov. 16. Clay is fused with Na_2SO_4 and H_2SO_4 , the product lixiviated and filtered and NaF soln. added to the filtrate of Na_2SO_4 and $Al_2(SO_4)_3$ soln. The Na_2SO_4 remaining in the soln. is filtered off and crystd. for further use in the process and the AlF_3 pptd. is fused with NaCl and the fused mixt. is electrolyzed to obtain metallic Al. The exhausted electrolyte is reused to form fresh AlF_3 .

Alloy for casting or stamping. C. R. DENTON. U. S., 1,162,226, Nov. 30. The alloy is formed of Cu 86, Ni 15, V 1, spelter 12, Sn 7 and Al 1 part. It is resistant to sea water and to most acids.

Alloy for magnet cores, etc. R. H. PATCH. U. S., 1,162,186, Nov. 30. Fe 60-70% (preferably 65%), Co 30-40% (preferably 34.5%) and Mn 0.2-2% (preferably 0.25%) are used. The alloy has a very great magnetic permeability.

An alloy for bullets. F. C. FRARY and S. N. TEMPLE. U. S., 1,158,671, Nov. 2. Pb is combined with about 2% of Ca and a small amt. of Cu as a hardening agent. The Ca serves to harden the alloy more than an equal amt. of Sb and gives a tougher and less brittle metal.

Alloy for bullets. F. C. FRARY and S. N. TEMPLE. U. S., 1,158,672, Nov. 2. Pb is combined with about 2% of a mixt. of Ca and Ba or Sr and Mg or other mixts. of alk. earth metals and with a small amt. of Cu as an additional hardening agent.

Alloy for cast bullets, type, etc. F. C. FRARY and S. N. TEMPLE. U. S., 1,158,673, Nov. 2. Pb is combined with 2-2.8% of Sr and 0.2-0.8% Cu.

Alloy for cast bullets, type, etc. F. C. FRARY and S. N. TEMPLE. U. S., 1,158,674, Nov. 2. Pb is combined with 3-6% of Ba and 0-0.25% Cu. The Cu, if used, reduces the hardness slightly but gives a finer texture to the alloy.

Alloy for cast bullets, etc. F. C. FRARY and S. N. TEMPLE. U. S., 1,158,675, Nov. 2. Pb is alloyed with Mg 0.5% and Cu 0.25-0.5%.

Uniting copper and tungsten. W. D. COOLIDGE. U. S., 1,162,339, Nov. 30. After being degasified the Cu is cast while molten and heated just sufficiently to make it flow readily against wrought W to which it is to be united, *in vacuo*.

Uniting copper with tungsten. W. D. COOLIDGE. U. S., 1,162,340, Nov. 30. W and Cu are heated together *in vacuo* to a temp. of about 1400° and the Cu is allowed to solidify in contact with the W *in vacuo*.

Solder for aluminium. J. CAYOCCA. U. S., 1,161,612, Nov. 23. Sn, Pb and Al, in the proportions of 64:16:5, resp., are used in making the solder.

Composition for cleaning metals to be soldered. V. LOGRASSO. U. S., 1,160,731, Nov. 16. ZnCl_2 4 oz., borax and H_3BO_3 1 teaspoonful each are dissolved in H_2O 1 gal.

Melting aluminium and its alloys. G. MELLEN. U. S., 1,160,430, Nov. 16. Al or its alloys are melted in a chamber from which the air has been first partially exhausted and the residual O then removed by displacement with a gas chemically inert to the Al.

Forming a protective coating on iron or steel. J. H. MADDY and B. H. SCHUBERT. U. S., 1,161,944, Nov. 30. Powdered Pb, Zn, Sn, Sb or alloy of low m. p., is mixed with HgCl_2 and sufficient liquid ZnCl_2 soln. to make a readily flowing mixt. which is then applied to the articles to be coated and heated on them to fuse the metal in the coating mixt.

Galvanizing iron or steel pipes. U. S. ARMSTRONG. U. S., 1,159,820, Nov. 9. After pickling the pipe in an acid bath, its inner surface is coated with varnish, Japan or similar partially combustible material which is resistant to water and acids, the pipe is again subjected to an acid cleaning bath and then is passed through a bath of molten coating metal to coat its outer surface and partly consume the coating on its inner surface.

Coating iron and steel sheets with lead or lead alloys. R. HAZELTINE. U. S., 1,161,475, Nov. 23. The sheets are passed through the molten coating metal and then through an overlying layer of palm oil. Within the latter are placed brass, bronze or Ni rolls which remove the surplus coating metal from the sheets.

Gold- and platinum-coated tungsten dental pins, etc. W. D. COOLIDGE. U. S., 1,162,342, Nov. 30. An alloy of Au and Pt is used to form a firmly adherent coating on ductile W (or Mo).

Concentrating ores. MINERALS SEPARATION, LTD. Brit., 17,327, July 21, 1914. In a froth-flotation process for concg. ores containing colloidal gang slimes, there is added at some stage of the process a small quantity of an electrolyte which either has a low dissociation const., such as a weak organic acid, or is a salt of such an acid, e. g., argol. The treatment may be combined with any of the known flotation processes. Cf. C. A. 9, 52.

Metallurgical furnace. NEW METALS-PROCESS CO. Brit., 17,322, July 21, 1914. A furnace for the reduction of metals, as Fe, Cu, Zn, or Pb from ores, comprises a relatively low reducing chamber, having an aperture at its lower end for the discharge of unconsumed fuel, metal, etc., in a solid state, to which fuel and ores are fed from a preheater heated by the combustion with air of gases withdrawn from the reducing chamber.

Metallurgical furnace. NEW METALS-PROCESS CO. Brit., 17,323, July 21, 1914. A furnace for the reduction of metal from ores, such as oxides or carbonates, includes a preheater, preferably in the form of an inclined rotary drum, which slowly feeds ore with excess of fuel to a comparatively low wide reducing chamber having a top opening for high bituminous fuel, and tuyères arranged to deliver air at a relatively short distance from the outlet to the preheater.

Metallurgical furnace. NEW METALS-PROCESS CO. Brit., 17,324, July 21, 1914. A furnace for the reduction of metal from ores, such as ferro-Mn, and other metals, and alloys such as ferro-Mn,

the ore, together with a large excess of coke or other solid fuel, passes through an inclined rotary preheating cylinder to a reducing chamber of the kind described in 17,323 (cf. preceding pat.). The air supply through the tuyères is controlled so as to produce a temp. of about 3500° F. in the reaction zone when reducing Fe ores, and the reduced metal in globular form, together with the unburnt C, sinks into a cooling chamber. The tuyère which is directed vertically downwards passes through an elbow connecting the pre-heater and reducer, and is cooled by H₂O circulation. The product is discharged into pits by a reciprocating plate having apertures. Bituminous fuel is charged into the furnace through an inlet. The reaction gases escape to a chimney through the pre-heating chamber, and any combustible components are consumed by air supplied through a tuyère. The unburnt C is sepd. from the metal and again used in the furnace. The upper part of the reducer is domed and provided with poke-holes. In the case of a complex ore, metals such as Cu and Pb may be extd. separately; otherwise, an alloy is produced.

Extracting metals. NEW METALS-PROCESS CO. Brit., 17,325, July 21, 1914. In distg. metals from the ores, a charge containing lump fuel in great excess is subjected to the action of a downdraught, without the formation of a slag, and the unconsumed solid fuel is sepd. from the gang, and any non-volatile metal, and used again.

Steel. A. HETHEY. Brit., 17,285, July 21, 1914. In dephosphorizing steel in a basic open-hearth or elec. furnace, Mn is added to the bath prior to addition of ore, and also from time to time during the process, for the purpose of preventing the soln. of oxide in the metal. The product may be carbonized by adding coke or coal after the removal of the slag, or molten Fe may be poured through the slag; ferro-silicon containing over 25% of Si may be added in the ladle. After dephosphorization, the slag may be solidified by the addition of lime or dolomite to prevent oxidation, and to allow the temp. to be raised before pouring.

Chromium-nickel steels. COMPAGNIE DES FORGES ET ACIERIES DE LA MARINE ET D'HOMECOURT. Brit., 16,687, July 13, 1914. Ti is added to the Cr-Ni steels described in 25,742, 1907 (C. A. 3, 775), just before pouring, in order to refine the metal and to bring the critical points closer together. It is added in the form of a 20-25% alloy, and in the proportion of 0.15-0.3%.

Copper alloy. C. R. DENTON. Brit., 17,157, July 20, 1914. A Cu alloy contains also Ni, V, Zn, Sn, and Al. The Ni and V are melted with the Cu, and fluxes are stirred into the mass. Zn is then added, and the temp. raised to 2000° F., whereupon the Sn and Al are added in succession.

Priming for bronze coatings on iron or sheet metal. A. KRUTZ. Ger., 285,060 Apr. 18, 1914. The article is provided first with a coating of minium, then with a layer consisting of 0.25 kg. gilder's size dissolved in 1 liter H₂O, 25 g. dextrin flour boiled with 55 g. H₂O, 2.55 g. K₂CrO₄ dissolved in 255 g. H₂O. These materials are mixed and stirred with the admixt. of china clay, whereupon the surfaces are polished coated with the size, bronzed and polished.

Zinc furnace receivers. METALLWERKE UNTERWESER AKT.-GES. Ger., 284,597 Oct. 11, 1913. The receiver is shaped up from a cylindrical tube.

Reducing and purifying zinciferous flue dust. TROLLHÄTTANS ELEKTROTHERMISKA AKTIEBOLAG. Ger., 284,866, May 10, 1914. The gases from elec. Zn furnace are conducted over a reducing layer of coal. The speed of the flowing gases is reduced by a suitable relative adjustment of the sizes of the coal compartment and the gas canals, so that entrained dust can deposit on the coal.

Transportation and working of flue dust. H. GLITZ. Ger., 284,850, June 10, 1913.

Pulverizing refuse slag. VESUVIO, ART.-GES. FÜR DEN BAU VON MÜLLVERBRENNUNGSANLAGEN. Ger., 284,336, Jan. 5, 1913.

Mold for cast iron and steel. F. SCHRUFF. Ger., 283,342, Dec. 30, 1913. Addition to 250,914.

Welding copper. C. CANZLER and R. SAMERSREUTER. Ger., 284,840, Oct. 1, 1912. Cu wire containing P, to which Ag is added, is used.

10. ORGANIC CHEMISTRY.

CHAS. A. ROUILLER.

Synthesis of α -tetronic acid. LEONORE KLETZ AND ARTHUR LAPWORTH. Manchester. *J. Chem. Soc.* 107, 1254-65(1915).— $\text{CH}_2\text{BrCH}_2\text{CHAcCO}_2\text{Et}$, prepd. by Freer and Perkins' method (*Ibid* 51, 838(1887)) in cold H_2SO_4 , when gradually treated with an equimol. amt. of $\text{O}_2\text{S(OH)ONO}$, the mixt. poured on ice and extd. with CHCl_3 , yielded an oil (A) from which *ethyl syn-oximino- γ -bromobutyrate*, $\text{CH}_2\text{BrCH}_2\text{C}(\text{NOH})\text{CO}_2\text{Et}$, needles from light petroleum, m. 49-50°, was isolated. When 25% aq. KOH was gradually added to (A) until the temp. remained const., the soln. acidified with HCl and extd. with a large vol. of AcOEt , the filtered exts. united and neutralized with 20% KOH (phenolph. indicator), the aq. soln. acidified and extd. with AcOEt or AcEt , and the exts. dried and evapd., *syn- α -oximinobutyrolactone* (B), $\text{CH}_2\text{CH}_2\text{O.CO.C}(\text{NOH})$, flat prisms from Et_2O or light petroleum, m. 107° (decompn.),

was obtained. (B) is acid to litmus, forms sol. Cu, Fe'', Hg', Ca, Ba, Sr, Na and K salts, but forms an insol. ppt. with $(\text{AcO})_2\text{Pb}$. (B) was not readily hydrolyzed and none of the available methods for the elimination of the NOH group led to the formation of compds. having well defined ketonic properties. 20 g. of crude $\text{BrCH}_2\text{CH}_2\text{CH}(\text{CO}_2\text{H})_2$, prepared by Carpenter and Perkins' method (cf. *Ibid* 75, 924(1899)), in 17 cc. H_2O , when treated with 6.5 g. of NaNO_2 in satd. aq. soln., gave an 80% yield of *anti- α -oximinobutyrolactone* (C), needles from AcOEt , m. 192° (decompn.), which, unlike (B), reduces Fehling soln. in the cold. When carefully heated with Br, (C) in H_2O or $\text{C}_6\text{H}_5\text{N}$ formed a *bromonitroso compound*, $\text{CH}_2\text{CH}_2\text{O.CO.CBrNO}$, brilliant blue

liquid which readily loses Br on treatment with org. solvents or hot H_2O . On reduction with Sn and ice-cold HCl, (C) formed $\text{CH}_2\text{CH}_2\text{O.CO.CHNH}_2$, m. 194°, identified

by conversion into the Bz deriv., m. 141°, and the free NH_2 acid, m. 185-6° (cf. Fischer,

Ber. 40, 110(1907)). *α -Telronic acid* (D), $\text{OC.O.CH}_2\text{CH}(\text{COH})$ or $\text{OC.O.CH}_2\text{CH}_2\text{CO}$ [possibly identical with Böttinger's " *α -ketobutyrolactone*," *Ann.* 260, 345(1890)], was best prepd. by the following method: 15 g. of Na_2SO_3 were gradually added to 5 g. (C) suspended in warm H_2O , the soln. heated on the H_2O bath, acidified with HCl and evapd. under diminished pressure. The viscous residue after repeated extn. with AcOEt , evapn. of the ext. *in vacuo*, and extn. of the residue with Et_2O , yielded a mixt. containing a small amt. of (D) which was sepd. by means of repeated crystn. from Et_2O . (D), needles or prisms from AcOEt , m. 111° (gradual decompn.); *phenylhydrazine* (E), yellow needles, m. 223-4°. When condensed with HONH_2HCl , (D) is converted into (C). (D) in H_2O is acid to litmus, reduces AgNO_3 in the cold, and gives a deep reddish violet color with FeCl_3 , thus differing from most α -ketonic acids and substituted α -ketolactones. (E) was much more readily obtained by the interaction of C, and PhNHNH_2 in AcOH , or from $\text{BrCH}_2\text{CH}_2\text{CH}(\text{CO}_2\text{Na})_2$ and PhN:NCl . (D) was also obtained, in very poor yield, by the action of hot mineral acids on (C), by the

interaction of $O_3S(OH)ONO$ and (C) in HCO_2H , or by the action of $FeSO_4$ and HCl on (C). The action of HNO_3 on various monoalkylmalonic acids was also investigated. The interaction of $PhCH_2CH(CO_2H)_2$ and $NaNO_2$ gave rise to $PhCH_2C(:NOH)CO_2Na$ (yielding the free acid, m. 155° ; cf. Erlenmeyer, ref. not given) or $PhCH_2CN$ (obtained from the above Na salt by the loss of $NaHCO_3$). When ethyl-, methyl- or allylmalonic acid was treated with HNO_3 under similar conditions, the reaction proceeded imperfectly, yielding large amts. of the unchanged acid together with nitriles formed by the withdrawal of $NaHCO_3$ from the expected oximino acids. The above method of prep. oximino acids is therefore not generally applicable.

LOUIS E. WISE.

Non-aromatic diazonium salts. IV. Thiazole-2-diazonium salts. GILBERT T. MORGAN AND GENEVIEVE V. MORROW. Roy. Coll. Sci., Ireland, Dublin. *J. Chem. Soc.* 107, 1291-6(1915).—M. and M. have detd. the best conditions for the diazotization of 2-aminothiazole (A) prepd. by Traumann's method (cf. *Ann.* 249, 35(1888)). (A) was very readily diazotized in 20% H_2SO_4 by means of N aq. $NaNO_2$ and the diazo compd. isolated as the *chloroaurate* (B), $[S.CH:CHN:C.N_2]AuCl_4$, yellow crystals, m.

122° (decompn.), stable at ordinary temp. and hydrolyzed by H_2O . An attempted diazotization of (A) in cold dil. HCl led to the formation of brown amorphous products [thiazolediazohydroxide(?); cf. Nef, *Ann.* 265, 110(1891)]. Diazotization of (A) in $HClO_4$ by means of $EtNO_2$ proceeded smoothly but formed an extremely explosive diazonium perchlorate. In HNO_3 the diazotization of (A) proved unsatisfactory, owing to the insolubility of the nitrate of (A). Solns. of thiazolediazonium salts when added to β -naphthol in $EtOH$ formed *thiasoleazo- β -naphthol*(?), brownish red plates from C_6H_6 , which partly dissolved in aq. $NaOH$, leaving a Cu-red flaky residue, m. 105° . The $NaOH$ soln. upon acidification yielded a pale red substance, m. 126° . Both of these fractions gave an intense purple color with H_2SO_4 . *Thiasoleazo- β -naphthylamine*, amorphous bluish red compd., m. $135-40^\circ$, gives an orange color with concd. H_2SO_4 and a magenta color on diln. CH_3Ac , reacting with thiodiazonium nitrate in the presence of $(NH_4)_2CO_3$ formed *thiasole-2-azoacetylaceton*, $S.CH:CH.N:CN:NCAc$:

CMeOH.

LOUIS E. WISE.

Action of alkalis on dextrose and levulose. CHARLES W. R. POWELL. Univ. Sidney. *J. Chem. Soc.* 107, 1335-46(1915).—A study of the combination between the sugars and alkalis in aq. solns., and the velocity of the ensuing decompn. The formation of a compd. in a soln. containing dextrose (or levulose) and $NaOH$ (or KOH) was detected by the following method: changes in conductivity produced by gradually increasing the concn. of the sugar in the alk. soln. were carefully noted. As the relative amt. of sugar was increased, the conductivity fell until a point was reached where the decrease suddenly became less marked. This change occurred when the soln. contained equimol. amts. of the sugar and $NaOH$ (or KOH). Dextrose and levulose therefore unite with $NaOH$ or KOH to form compds. containing the substances in equimol. proportions. These compds. are largely hydrolyzed by H_2O , the degree of hydrolysis being of the same order of magnitude in the case of dextrose and levulose. The velocity of decompn. of the 2 sugars by alkalis was detd. by noting the gradual vol. changes in delicate dilatometers. The velocity consts. for the reaction between the sugars and $NaOH$ were calcd. from the equation: $k = 2.3 / t \cdot \log[a/(a-x)]$, where a is the initial concn. of sugar and x is the amt. decompd. in the time t (dilatometer scale readings being taken at the beginning and at the end of the reaction). The results have been tabulated. The reaction under the influence of alkalis were shown to be due to the rapid conversion of the sugar under the influence of alkalis at a slower rate.

to form the salts of various acids. The velocity coeff. for the decompn. of dextrose depends very little on the concn. of free dextrose, but largely on the concn. of HO ion, to which, however, it is not exactly proportional. Excess of alkali acting upon dextrose or levulose at 50° causes the decompn. of about 50% of the sugar.

LOUIS E. WISE.

Formation of heterocyclic compounds from cyanoacetamide and hydroxymethylene ketones. I. HEMENDRA K. SEN-GUPTA. Royal Coll. Sci., London. *J. Chem. Soc.* 1915, 1347-67 (1915).—The paper deals mainly with the condensation of hydroxymethylene cycloketones with $\text{NCCH}_2\text{CONH}_2$ (A), which led to the formation of quinoline derivs. (A) in H_2O when treated with an equimol. amt. of freshly prepd. $\text{CH}_2\text{CH}_2\text{CH}_2\text{CO.C}(\text{:CHOH}).\text{CH}_2$ (B), in the presence of a small amt. of

piperidine or Et_3NH , sufficient alc. added to effect soln. and the mixt. allowed to stand overnight, yielded 2 products: 3-cyano-9-hydroxyoctahydro-2-quinolone (C),

$\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{C}(\text{OH}).\text{C}:\text{CH}.\text{CH}(\text{CN}).\text{CO}.\text{NH}$, does not m. 290°; and 3-cyano-octahydro-2-quinolone (D), $\text{CH}_2(\text{CH}_2)_3\text{C}:\text{N}.\text{CO}$, prisms, m. 249°, sepd. by repeated

crystn. from AcOH. (C) was also prepd. in purer form, though in very poor yield, by treating (B) with $\text{NCCH}_2\text{CO}_2\text{Et}$ in the presence of NH_3 in abs. alc., or from the amide of (B) and $\text{NCCH}_2\text{CO}_2\text{Et}$ in alc. in the presence of Et_3NH or piperidine. (C) when heated in glacial AcOH at 200-10° for several hrs. was converted into (D). The 9-methyl ether of (C), long needles, m. 247°, hydrolyzed by H_2SO_4 to an acid m. 200-2°. (D) was also formed by condensing the acetate of (B) with (A) in the presence of EtONa . Hot 80% H_2SO_4 hydrolyzes both (C) and (D), giving rise to hexahydro-2-quinoline-3-carboxylic acid (E), needles from AcOH, m. 266-7° (decompn.). When heated with fuming HCl at 120-30°, (C) and (D) yield (E). If the hydrolysis is carried out at 150-60°, CO_2 is evolved in either case and hexahydro-2-quinolone,

$\text{CH}:\text{C}(\text{CH}_2)_4\text{C}:\text{N}.\text{CO}.\text{CH}_2$ (F), m. 202-4°, is obtained. (F) was also formed by

heating (E). When treated with PCl_5 , (F) yields 2-chlorotetrahydroquinoline, oil, and when heated at low red heat with Zn dust in a current of H, (F) gives rise to quinoline, identified by means of its picrate and methiodide. The condensation of 3-methylhydroxymethylenecyclohexanone (G) and (A) gave rise to 3-cyano-9-hydroxy-7-methyloctahydro-2-quinolone, m. 272° (decompn.), and 3-cyano-7-methylhexahydro-2-quinolone, m. 255-6°, the latter being formed from the former by heating at 200-10° in a sealed tube. Both compds. on hydrolysis give rise to 7-methylhexahydro-2-quinolone-3-carboxylic acid (H), needles, m. 259° with the evolution of CO_2 and formation of 7-methylhexahydro-2-quinolone, needles, m. 192-3°. The condensation of $\text{NCCH}_2\text{CO}_2\text{Et}$ with (G) gave rise to ethyl α -cyano- β -[2-keto-4-methylcyclohexylidene]propionate, $\text{CH}_2\text{CHMe}.\text{CH}_2\text{CO.C}[\text{:CHCH}(\text{CN})\text{CO}_2\text{Et}].\text{CH}_2$, m. 184-5° (accidentally sepd. in

the pure state in an attempt to form the semicarbazone), exceedingly difficult to purify, giving a red coloration with FeCl_3 , and hydrolyzed to (H) when heated with H_2SO_4 or with alc. KOH. Its hydraside m. 263-5°. 4-Methylhydroxymethylenecyclohexanone, m. 108-9°, when acted upon by (A) formed 3-cyano-6-methylhexahydro-2-quinolone, m. 229°. The corresponding 3-cyano-9-hydroxy-6-methyloctahydroquinolone, does not m. 290°, was formed by heating (A) with (G) in abs. alc. NH_3 as the condensing agent. Both quinolones on hydrolysis give rise to hexahydro-2-quinolone-3-carboxylic acid, m. 284° with evolution of CO_2 . The condensation of 6-methylhexahydro-2-quinolone, m. 205-6°.

The condensation of 2-methylhydroxymethylenecyclohexanone and (A) gave rise to 3-cyano-8-methylhexahydro-2-quinolone, prisms, m. 242°, yielding on hydrolysis the corresponding acid, m. 260-1° with elimination of CO₂ and the formation of 8-methylhexahydro-2-quinolone, m. 142°. Hydroxymethylenementhone, when condensed with (A), formed 3-cyano-5-methyl-8-isopropylhexahydro-2-quinolone,

$\text{CH}:\text{C}(\text{CHMe}.\text{CH}_2.\text{CH}_2.\text{CH}(\text{CHMe}_2).\text{C}:\text{N}.\text{CO}.\text{CHCN})$, thin prisms, m. 227-8° (de-

compn.), yielding the corresponding acid, soft plates, m. 182-4°, on hydrolysis. (A) and EtCOCMe:CHOH formed 3-cyano-5-methyl-6-ethyl-2,3-dihydro-2-pyridone, N:CEt.CMe:CH.CH(CN).CO, m. 230-1°, yielding the corresponding acid, m. 287-8°,

which evolves CO₂ and forms the corresponding hydroxypyridine derivative, prisms, m. 110°, resolidifying, and rem. 138-9° (m. 141° after dehydration). The condensation of NCCH₂CO₂Et and EtOCH:CACCO₂Et in the presence of NH₃ led to 6-hydroxy- α -picoline, m. 212-3° (obtained by a similar reaction by Errera, Ber. 33, 2969(1900)). Condensation between ethoxymethyleneacetylacetone and (A) could not be effected in the presence of piperidine or Et₃NH, hence the Na salt of (A) was used in the reaction, and the resulting product pptd. by adding HCl to the reaction mixt. This compound, C₁₂H₁₄O₂N₂, m. 229-30°, formed a methyl ether, plates, m. 170°; an ethyl ether, fine needles, m. 110°; and a corresponding acid, C₁₂H₁₄O₂N, m. 242-3°. Condensation of the Na salt of (A) and dibenzylidenecyclohexanone formed a compound, C₂₂H₂₂O₂N₂, prisms, m. 262-3° (decompn.), insol. in acids and alkalies and giving no color with FeCl₃, which when hydrolyzed with HCl formed a compound, C₂₂H₂₂ON, needles, m. 248-9°, insol. in aq. acids or alkalies, giving a deep color with FeCl₃. This type of condensation with benzylidene ketone derivs. is apparently general. PhCH:CHAc and (A) reacting normally gave rise to a compound, C₁₃H₁₄O₂N₂, m. 257-8°, excepting when the reaction was carried out in alc. in the presence of Et₃NH. Under these conditions was formed a compound, C₁₃H₁₄O₂N₂, needles, m. 276° (decompn.), yielding a methyl ether, needles, m. 146°. The disappearance of the 2 H atoms in the formation of this product has not been satisfactorily accounted for. The condensation of (A) and acetylcyclohexanone was readily effected in the presence of Et₃NH, the resulting compound, C₁₁H₁₂ON₂, needles, m. 290°, yielding on hydrolysis at 150-60° with HCl a derivative, C₁₀H₁₂ON, m. 235°. The structure of these compds. has not been definitely determined.

LOUIS E. WISE.

Complex metallic amines. I. *cis*-Sulfonyldiacetatodiethylenediaminecobaltic salts. THOMAS S. PRICE AND SIDNEY A. BRAZIER. Municipal Tech. School, Birmingham. J. Chem. Soc. 107, 1367-76(1915); cf. C. A. 9, 566.—The interaction of carbonatodiethylenediaminocobaltic bromide (A), Ag₂O and S(CH₂CO₂H)₂ lead to the formation, not of the expected hydrogen thiodiacetate, but of the double salt of cobalt thiodiacetate and ethylenediamine thiodiacetate, S(CH₂CO₂)₂Co.S(CH₂CO₂H)₂C₂H₄(NH₂)₂.2H₂O, which could be directly prepd. from CoCO₃, C₂H₄(NH₂)₂, and S(CH₂CO₂H)₂, and which, when treated with AgNO₃, gave a quant. yield of S(CH₂CO₂Ag)₂. The following *cis*-sulfonyldiacetatodiethylenediaminecobaltic salts are described (R = [SO₂(CH₂CO₂)₂-Co.en₂]): bromide (B), RBr.2H₂O, dull rose-red microscopic plates, from (A) and SO₂-(CH₂CO₂H)₂; RCO₂CH₂SO₂CH₂CO₂H, previously described; iodide, RI, rose-red microcrystals, from (B) and KI; chloride, RCl.H₂O, rose-red platelets, from (B) and freshly prepared AgCl, undergoing decompn. when heated for 3 hrs. at 115°; nitrate, RNO₂.2H₂O, clusters of pale red microprisms, from (B) and AgNO₃; thiocyanate, RSCN, brick-red microcrystals, from (B) and KSCN; dithionate, R₂S₂O₆, from (B) and Na₂S₂O₆, small rose-red leaflets; chloroplatinate, R₂PtCl₆, pale brown microcrystals; chloroaurate, RAuCl₄.H₂O, burnt sienna microcrystals, after air drying. Oxalatodiethylenediamine-

cobaltic bromide was prepd. by a method similar to that used in the prepn. of (B). The properties of the salt corresponded with those described by Werner and Vilmos (*Z. anorg. Chem.* 21, 153(1899)).

LOUIS E. WISE.

New halogen derivative of camphor. I. α' -Chlorocamphor. Isomerism, static and dynamic. THOMAS M. LOWRY AND VICTOR STEELE. Guy's Hosp., London. *J. Chem. Soc.* 107, 1382-96(1915); cf. *C. A.* 9, 2893.—A more detailed description of the synthesis and properties of α' -chlorocamphor (A). A kg. of α -chlorocamphor (B) in 1 l. of boiling 96% alc. (freshly distd. after boiling with KOH) was treated with 75 cc. of 0.1 N NaOEt, the boiling continued for 0.5 min. and the soln. acidified with aq. HCl, and rapidly cooled in ice H_2O . The less sol. residual (B) sepd. after the mixt. was cooled to -18° ; the mother liquor after evapg. nearly to dryness, yielded (A), which after recrystn. to const. $[\alpha]_{441}$ finally yielded a product m. 117° free from (B). The $[\alpha]_{25}^\circ$ in 95% alc., 5 g. per 100 cc., were as follows (wave lengths of the sources of monochromatic light being given in parentheses): (6708) 23° ; (5893) 35° ; (5780) 38° ; (5461) 47° ; (4358) 129° . The $[\alpha]$ previously reported were of a sample of (A) which had been crystd. only to const. m. p. L. and S. have since shown that as much as 10% of (B) may contaminate (A) without altering its m. p. A satd. alc. soln. of (A) when treated with a drop of EtONa in alc. undergoes rapid isomeric change, evolving heat and yielding (B). Mutarotation in alk. soln. of (A) was similar to that observed by Kipping in the case of (B), each substance being converted by alkalis into the same mixt. of isomerides in equil. (A) when brominated gives rise to the same isomorphous mixt., m. $55-8^\circ$, as that formed by (B) on bromination. Judging from the $[\alpha]_D^{21}$ in $CHCl_3$, 52.2-52.6°, both components of this mixt., which consists of α -chloro- α' -bromo- and α' -chloro- α -bromocamphor, are formed in equal amts., a fact which serves as a confirmation of Lapworth's theory according to which the replacement of H by halogen in keto compds. is preceded by the addition of the halogen to an enolic isomer of the ketone (cf. *Ibid* 85, 30(1904). Nitration of (A) yielded only α' -chloro- α -nitrocamphor, m. 132° . A study of the relationship between (A) and (B), which is in many ways analogous to that existing between the ketonic and the enolic components of acetoacetic ester, has led L. and S. to urge that the words "tautomeric" and "desmotropic" be used in the sense of the original definitions, *tautomerism* covering such cases as the 1,2- and 1,6-dibromobenzenes, *desmotropy* referring to all cases in which there is a rearrangement of the bonds consequent upon the displacement of a mobile H atom, and *dynamic isomerism* including all cases in which isomerism passes from a static to a dynamic condition.

LOUIS E. WISE.

Metallic derivatives and constitution of guanidine. HANS KRALL. M. A. O. Coll., Aligarh, India and Trinity Coll., Dublin. *J. Chem. Soc.* 107, 1396-1405(1915).—Of the 3 possible tautomeric forms of guanidine, the one usually written, $HN:C(NH_2)_2$, has not been established. HNO_2 , even when an excess of the strong acid is present, liberates N corresponding to only 1 NH_2 group, and reacts very slowly. The dihydrochloride of guanidine could not be prepd. The other possible tautomeric forms, $H_2NC:N.NH_2$ (A) and $HN:C.NH.NH_2$ (B), corresponding to the constitutions sug-

gested for carbamide by E. A. Werner (*Ibid* 103, 1013(1913)) are probably present in guanidine solns. in the form of an equil. mixt. The constitutions (A) and (B) are in strict accordance with the relation of guanidine to cyanamide, and serve to explain its hydrolysis and the formation of its metallic and Me derivs., as well as its behavior when forming salts. The hydrochloride yielded no trace of NH_3 when solid residue (from the alc. soln.) evolved NH_3 , soln. was treated with 1 equiv. of EtOK and

distd. At no point in the distn. was the brisk evolution of NH_3 noted, gradual decompn. taking place with the formation of K cyanamide. When the expt. was repeated with 2 equivs. of EtOK , only traces of NH_3 were liberated below 160° . Hydrolysis of guanidine with H_2O led to the formation of NH_3 , CO_2 , and small amts. of melamine. No urea was formed. The interaction of concd. solns. of guanidine and Ag nitrates led to the formation of the *double salt*, $\text{CH}_5\text{N}_3\cdot\text{HNO}_3\cdot 2\text{AgNO}_3$, needles. When the above in H_2O was rendered alk. a flocculent ppt. formed, which varied in color from white through yellow to grey, depending on the proportions used. A *monosilver derivative*, $\text{HN}:\text{C.NAg.NH}_2$ (C), colorless granules, not exploding when struck, but decomposing

with a mild explosion when strongly heated, was formed by treating a soln. of guanidine nitrate with 5 equivs. of NaOH and 1 equiv. of AgNO_3 . When 2 equivs. of AgNO_3 were added to guanidine solns. containing an excess of alkali, a very explosive black *disilver derivative*, $\text{Ag}_2\text{N}:\text{C.NAg.NH}_2$, was formed. When an excess of alkali is avoided,

guanidine solns. and AgNO_3 yield a yellow substance (D), identical with a compd. prepd. by Thiele (*Ann.* 302, 334) and believed by him to be $\text{CH}_5\text{N}_3\text{Ag}_2\cdot\text{H}_2\text{O}$. (D) does not contain H_2O , is stable, and is apparently an equimol. mixt. of (C) and a non-explosive *disilver derivative*, $\text{Ag}_2\text{N}:\text{C}:\text{N.NH}_2$ (derived from (A)). This hypothesis is

in harmony with Schenck's observations (*C. A.* 4, 1475) that (D) yields a mixt. of the mono- and dimethylguanidines on alkylation. When treated with HCl , (D) forms guanidine hydrochloride and AgCl . Dil. aq. solns. of guanidine and Cu salts, when treated with alkali formed a green *monocopper derivative*, $\text{Cu}:\text{N}:\text{C}:\text{N.NH}_2$.

A blue *copper salt*, $\text{C}_2\text{H}_5\text{N}_3\text{ClCu}(\text{?})$, was formed when 20 g. of guanidine hydrochloride in 50 cc. H_2O were treated with 25 g. KOH in 50 cc. H_2O and 13 g. CuCl_2 in 100 cc. H_2O added. This compd., when hydrolyzed, yielded $\text{Cu}(\text{OH})_2$, guanidine, and guanidine hydrochloride.

LOUIS E. WISE.

Phenylsuccinic acid series. II. Some derivatives of the optically active diphenylsuccinic acids. HENRY WREN AND CHARLES J. STILL. Belfast. *J. Chem. Soc.* 107, 1449-59(1915); cf. *C. A.* 9, 2223.—Pure *d*-diphenylsuccinic acid (A) yields a *barium salt*, well defined prisms containing 5 mols. of H_2O , 4 of which are lost at $100-5^\circ$, the 5th being expelled at $200-1^\circ$. The anhydrous salt dissolves in 330 parts H_2O at 7° . (A) and the *l*-isomer (B) react with MeOH and H_2SO_4 , yielding, resp., the *d*-ester, platelets m. $165-6^\circ$, $[\alpha]_D^{18.3}$ (acetone) 341.9° , $[\alpha]_D^{15.8}$ (CHCl_3) $376-8^\circ$, and the *l*-ester, platelets, m. $165-6^\circ$, $[\alpha]_D^{15.8}$ (acetone), -342.1° , $[\alpha]_D^{14.2}$ (AcOEt) -365.3° , $[\alpha]_D^{16.3}$ (CCl_4) -431.8° . *Methyl dl*-diphenylsuccinate, rhombic platelets, m. $173.5-4.0^\circ$; *methyl meso*-diphenylsuccinate, fine needles, m. $218.5-9.5^\circ$. Esterification of (A) and (B) with EtOH proceeded less rapidly than with MeOH . *Ethyl l*-diphenylsuccinate, rectangular plates, m. $104-5^\circ$, $[\alpha]_D^{16.4}$ (acetone) -279.7° . *Ethyl d*-diphenylsuccinate (C), plates, m. $104-5^\circ$, $[\alpha]_D^{18}$ (acetone) 279.4° . ($[\alpha]_D$ in other solvents are given.) During the purification of (C) by treatment with Na_2CO_3 (to remove unchanged acid) the *ethyl sodium d*-diphenylsuccinate, pearly leaflets, containing 4 H_2O , was isolated. A similar salt obtained from the *l*-acid, after decompn. with aq. H_2SO_4 and extn. with Et_2O , yielded *ethyl hydrogen l*-diphenylsuccinate, cryst. powder, m. $113.5-4.5^\circ$, readily electrified when gently rubbed, $[\alpha]_D^{16.5}$ (acetone) 328.7° . ($[\alpha]_D$ in other solvents are given.) (A) was not appreciably racemized by treatment with hot aq. KOH , but very appreciable racemization occurs upon hydrolysis of the optically active esters with alc. KOH . AcCl acting upon (B) at 30° gave rise to *l*-diphenylsuccinic anhydride (D), oblique prisms, m. $105.5-6.5^\circ$, $[\alpha]_D^{17.4}$ (C_6H_6) -278.7° ; the corresponding *d*-anhydride (E), prisms, m. $105.5-6.5^\circ$, $[\alpha]_D^{18.6}$ (C_6H_6) 286.2° . The latter was also ob-

tained by the action of SOCl_2 on (A). When treated with hot H_2O , (D) and (E) pass into (B) and (A), resp., the active acids, however, containing about 8% of inactive material from which a small amt. of the corresponding *meso*-acid could be isolated after fractional crystn. of Ba salts. The action of cold EtOH on (B) appears to be complex, a mixt. of ethyl hydrogen esters ($[\alpha]_D -260^\circ$ in EtOH) being probably formed, although no pure substance could be isolated.

LOUIS E. WISE.

Volatile oil of *Cymbopogon sennaarensis*, Chiov. OSWALD DIGBY ROBERTS. Imp. Inst., London. *J. Chem. Soc.* 107, 1465-70 (1915).—"Mahareb" grass when distd. with steam yielded 1.2% of a pale yellow oil, possessing an odor of pennyroyal, $d_{15}^{20} 0.9422$, $\alpha_D^{23} 29^\circ 38'$; acid no., 4.2; ester value before acetylation, 14.5; after acetylation, 62.1. The approx. compn. of this oil was as follows: Terpenes [including *d*-limonene (identified by conversion to the tetrabromide, m. $103-4^\circ$), and probably pinene], 13%; ketones [chiefly or entirely Δ' -menthenone (A), $d_{15} 0.9387$, $\alpha_D^{25} 1^\circ 44'$, b. $235-7^\circ$ (cf. Wallach and Meister, *Ann.* 362, 272 (1908); Schimmel's Reports, Oct., 1910, p. 97)] 45%; a *sesquiterpene alcohol*, $\text{C}_{15}\text{H}_{26}\text{O}$ (B), $b_{11} 170-3^\circ$, $d_{15}^{16} 0.9544$, $\alpha_D^{24} 10^\circ 48'$, 25%; an undetd. alc. with rose-like odor, 3%; unidentified phenol, yielding a benzoate, m. $70-2^\circ$, 0.2%; acids (probably AcOH, octoic, decoic, both in the free state and as esters and palmitic as an ester) 2%. The residue probably consisted of sesquiterpenes, 11.8%. The α - and β -semicarbazones and the oxime and oxamino-oxime of (A) were prepd., and agreed in properties with those given in Schimmel's Reports. The *bisnitroso derivative* of (A), microcrystals, m. $96-7^\circ$ (decompn.). The decompn. of (A) by means of neutral KMnO_4 lead to the formation of α -hydroxy- α -methyl- α' -isopropyladipic acid, diosphenol, m. 82° , and an unidentified acid, m. $126-7^\circ$. (A), when reduced with Na and EtOH formed, menthol. When distd. under reduced pressure, over P_2O_5 and finally over Na, (B) yielded a practically odorless sesquiterpene b. $150-5^\circ$, $d_{15}^{16} 0.9114$, $\alpha_D^{23} 24^\circ 24'$.

LOUIS E. WISE.

Polymorphic phthalyl-halogen-substituted-phenyl- and -tolylhydrazides. FREDERICK D. CHATTAWAY AND ERNEST VONDERWAHL. Oxford. *J. Chem. Soc.* 107, 1503-9 (1915).—The compds. listed were prepd. in order to det. the effect of halogen substituents upon the cryst. structure of phthalylphenyl- and phthalyltolylhydrazides, and to note whether any of the halogen compds. could be readily obtained in polymorphic forms. All of the compds. were readily formed by dissolving $\text{C}_6\text{H}_4(\text{CO})_2\text{O}$ and equiv. amts. of the corresponding hydrazine in alc., evapg. to dryness and heating at 100° , and crystg. from suitable solvents. *Phthalyl-o-chlorophenylhydrazide*, $\text{C}_6\text{H}_4(\text{CO})_2\text{N} \cdot \text{NHC}_6\text{H}_4\text{Cl}$, clusters of compact pale yellow plates, m. 221° ; *m*-isomer, pale yellow, slender, hair-like prisms, m. 180° ; *phthalyl-o-bromophenylhydrazide*, clusters of compact pale yellow plates, m. 212° ; *m*-isomer, pale yellow, hair-like prisms, m. 208° ; *o*-iodophenylhydrazide, crystals in 2 polymorphic forms, almost colorless clusters of hair-like needles, and bright yellow, compact rhombic plates, m. $144-5^\circ$; *m*-isomer, long, very slender prisms, m. 232° ; *p*-isomer, bright yellow prisms, m. 193.5° ; *2,6-dibromophenylhydrazide*, crystg. in 2 polymorphic forms, pale yellow microprisms, m. 203° , which when suspended in PhMe at room temp. are converted into large transparent, colorless, 6-sided, rhombic plates, showing signs of m. 190° and transformed at this temp. into the yellow variety, m. 203° ; *3,5-isomer*, faintly yellow, long, hair-like prisms, m. 268° ; *3,4-isomer*, small, pale yellow needles, m. 200° ; *2,4-isomer*, pale yellow, hair-like prisms, m. 224° . *2,4-Dichlorophenylhydrazide*, pale yellow, hair-like prisms, m. 206° ; *2-chloro-4-bromophenylhydrazide*, very pale yellow, hair-like prisms, m. 210° ; *4-chloro-2-bromophenylhydrazide*, practically indistinguishable from its isomer, m. 211° . *2,4,6-Br_3C_6H_2NHNH_2* was prepared by adding *2,4,6-Br_3C_6H_2NH_2* to a mixt. of its own wt. of H_2SO_4 and 7 times its wt. of AcOH, diazotizing at $3-5^\circ$, and reducing the mixt. with a slight excess of SnCl_2 . The *hydrochloride* of the hydrazine forms colorless plates; the free base, white needles,

m. 146° (cf. Neufeld, *Ann.* 248, 96(1888)). The other halogen-substituted phenylhydrazines used in the prepn. of the following compds. were synthesized by very similar methods: *Phthalyl-2,4,6-tribromophenylhydrazide*, pale yellow, compact prisms, m. 295°; *2,4,6-trichlorophenylhydrazide*, stout, nearly colorless prisms, m. 191°; *2,6-dichloro-4-bromophenylhydrazide*, pale yellow, compact rhombic plates, m. 188°; *2,4-dichloro-6-bromo isomer*, pale yellow, short, stout prisms, terminated by pyramids, m. 193°; *4-chloro-2,6-dibromophenylhydrazide*, compact, pale yellow prisms, m. 217°; *6-chloro-2,4-dibromo isomer*, pale yellow, compact, irregular plates, m. 195°; *phthalyl-3,5-dibromo-tolylhydrazide*, 3,5,6-Br₃[C₆H₄(CO)₂NNH]C₆H₂Me, long, colorless, slender prisms, m. 236°; *p-isomer*, crystg. in 2 polymorphic modifications, pale yellow needles, which when left in AcOH at ordinary temp. change into pale yellow, compact crystals (apparently short, stout prisms), m. 196°.

LOUIS E. WISE.

Optical rotatory power of derivatives of succinic acid in aqueous solutions of inorganic salts. III. GEORGE W. CLOUGH. Birkbeck Coll., London. *J. Chem. Soc.* 197, 1509-19(1915).—Since it has been shown that inorg. salts exercise a very marked influence on the $[\alpha]_D$ of various HO derivs. of (CH₃CO₂H)₂ (cf. Stubbs, *C. A.* 6, 956; Clough, *C. A.* 8, 1569; 9, 2622), C. has undertaken the study of the effect of various salts on the $[\alpha]$ of aspartic acid (A) and of asparagine (B). The influence of these salts appears to be analogous to that of the same salts on the $[\alpha]$ of malic and tartaric acids in H₂O. The $[\alpha]_D$, $[\alpha]_{Hg}$ green, and $[\alpha]_{Hg}$ violet of (A) and (B) at various temps. were detd. A change in sign in the case of the $[\alpha]$ of (A) at elevated temps. was noted. NaCl and BaCl₂ increased the $[\alpha]$ of (A), the latter salt having the greater effect. The enhancing effect of varying concns. of aq. HCl on the $[\alpha]$ of (A) and the *l*-rotation caused by the addition of different strengths of NaOH to (A) solns., together with the salt effects, have been recorded in tabular form. (A) in H₂O shows an anomalous rotatory dispersion. The influence of NaOH, KNO₃, KI, KBr, KCl, NaCl, NH₄Cl, BaCl₂, BaBr₂ and HCl on the $[\alpha]$ of (B) was also detd. The Ba salts cause a greater alteration in $[\alpha]$ than do the K salts which in turn possess greater influence than do the Na salts. The rotation-temp. curves of (A) in H₂O, in *N* HCl, and in *N* NaOH have been drawn and compared with those of Et hydrogen aspartate and EtNa aspartate. The 2 latter were drawn from the data given by Piutti and Magli, *Gazz. chim. ital.* 36, [II], 738(1906), and the comparison made since these compds. are *d*-rotatory at lower and *l*-rotatory at higher temps. Their rotation-temp. curves show marked similarity to those of (A). C., after a critical review of the literature on the subject of salt effects upon rotation, concludes that the changes in the $[\alpha]$ of the NH₂ and HO derivs. of (CH₃CO₂H)₂ are not due to a phys. alteration in the mol., as suggested by previous investigators, but "are to be ascribed to a more decidedly chem. character, probably a combination of the compds. in soln."

LOUIS E. WISE.

Constitution determinations in the camphene series. VI. Isomerism of methylcamphenilol and camphene hydrate. OSSIAN ASCHAN. Univ. Helsingfor. *Ann.* 410, 222-39(1915); cf. *C. A.* 7, 3478.—Methylcamphenilol and camphene hydrate are geometrical isomers. The same camphene hydrate is obtained by the action of Ca(OH)₂ upon (1) the product of the addition of HCl to camphene and (2) and (3) the chloride obtained by the action of PCl₅ upon borneol and isoborneol. Ac₂O gives an *acetate*, C₁₅H₁₇OAc, b₁₆ 103-5°, d₁₆¹⁵ 0.9852. Upon sapon. a mixt. of camphene hydrate and isoborneol was obtained. *Phenylurethan*, m. 89°. Methylcamphenilol was prepd. by adding the ketone to the MeMgI soln., and by adding the MeMgI to the ketone. The 2 products showed about the same m. p., 96°, but differed in optical activity, the 1st being $[\alpha]_D^{18.6}$ 16.6°, the 2nd $[\alpha]_D^{21}$ 12.7°. 10 g. of the alc. dissolve in 1.5 g. petr. ether. *Phenylurethan*, m. 126°. The alc. loses H₂O when heated 2 hrs. with 20%

H_2SO_4 . The camphene shows about half the rotation of the original material. Acetate, prepd. by warming the mixt. 26 hrs. at 100° , b_{11} $100-2^\circ$, d_4^{18} 1.003, $[\alpha]_D^{18}$ 18.9° . The sapon. requires 20-24 hrs., and gives pure methylcamphenilol. This is only slightly decompd. by boiling AcOH, while camphene hydrate is nearly completely changed into camphene. The following method serves to distinguish the 4 alcs.: The sample is dissolved in 0.5 cc. AcOH, 0.05 cc. 50% H_2SO_4 added, the mixt. boiled 10 sec., and then cooled to 10° . Borneol crystals out at once. Isoborneol: the liquid becomes turbid when cooled to 0° but clears up when warmed to 18° . Methylcamphenilol: the test does not become turbid upon cooling. Camphene hydrate: the sample becomes turbid while heating and forms a noticeable layer upon cooling. VII. The camphenonic acids and their optically active components. *Ibid* 240-56.—*dl*-Camphenonic acid is best prepd. by boiling 50 g. *dl*-camphenonic acid with 72 g. Ac_2O 6 hrs. and then distg. in a stream of CO_2 at ordinary pressure. The acid dists. undecompd. at $310-312^\circ$. Yield, 37.5 g. 100 g. H_2O dissolves 0.921 g. acid. The acid is resistant to boiling alk. KMnO_4 and to a boiling mixt. of concd. and fuming HNO_3 . This indicates that the CO group is between 2 tertiary C atoms. *Oxime*, crystals from C_6H_6 with C_6H_6 of crystn., m. 173° . Heated with 2.1 equivs. of Na in alc. 5 hrs. at $180-200^\circ$ in a tube, it gives a camphenonic acid, m. $134-5^\circ$. Since camphenonic acid is (I), camphenonic acid must be (II). *Ethyl ester*, liquid. It does not

react with BzH . *Amide*, 4-sided plates or leaflets, m. $184-5^\circ$. Reduced with Na and EtOH, the acid gives *dl*-camphenolic acid, $\text{C}_9\text{H}_{14}(\text{OH})\text{CO}_2\text{H}$, isolated as the Na salt, monoclinic crystals, m. $99-100^\circ$. *d*-Camphenonic acid is obtained as a by-product in the prepn. of the *dl*-acid and is purified by crystn. from C_6H_6 and then from H_2O . It is also prepd. from *d*-camphenonic acid. Long needles, with 1 mol. H_2O , m. 70° ; 100 g. H_2O dissolved 1.117 g. at 19° ; $[\alpha]_D^{20}$ 79.1° . *Amide*, plates, m. $152.5-4^\circ$, $[\alpha]_D^{20}$ 56.6° . Heated with KOH this gives *d*-camphenonic acid. *l*-Camphenonic acid, needles, with 1 mol. H_2O , m. 70° , anhydrous, m. $105-6^\circ$; 100 g. H_2O dissolves 1.112 g. at 19° ; $[\alpha]_D^{20}$ -79.2° . *Amide*, m. $152.5-4^\circ$, $[\alpha]_D^{20}$ -58.3° . The *dl*-acid and amide were synthesized from the components.

C. J. WEST.

Reactions in energy-rich solvents. I. The direct replacement of the sulfo group by chlorine. HANS MEYER. Univ. Prag. *Monatsh.* 36, 719-22(1915).— SOCl_2 , acting upon aromatic SO_3H acids, their salts, chlorides, or anhydrides for several hrs. at $160-200^\circ$, forms the chlorinated hydrocarbon. Thus, *p*- $\text{ClC}_6\text{H}_4\text{SO}_3\text{H}$ heated 7 hrs. with SOCl_2 at 180° gave *p*- $\text{C}_6\text{H}_4\text{Cl}_2$. PhSO_3Na gave PhCl . The anthraquinone- α - and β -sulfonic acids gave the corresponding chloroanthraquinones, but these proved difficult of purification. II. A direct replacement of the nitro group by chlorine and a new method of chlorination. *Ibid* 723-30.— SOCl_2 is capable of replacing the NO_2 group by Cl. Thus $\text{HO}_3\text{SC}_6\text{H}_3(\text{NO}_2)\text{Cl}$, heated with SOCl_2 10 hrs. at $160-80^\circ$, gave 1,2,4- $\text{C}_6\text{H}_3\text{Cl}_3$. *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{Cl}$ gave *C}_6\text{H}_4\text{Cl}_2. The formation of PhCl from PhNO_2 was quant. when the reaction was carried out for 10 hrs. at $190-200^\circ$. With *m*- $\text{O}_2\text{N}-\text{C}_6\text{H}_4\text{SO}_3\text{H}$, besides *m*- $\text{C}_6\text{H}_4\text{Cl}_2$, two substances were obtained, depending upon the time; a substance, needles, m. 82° or 96° , contains Cl and N (9 hrs. at $180-200^\circ$) or a substance, m. $165-75^\circ$, N-free but rich in Cl (13 hrs.). 1,5-Dinitroanthraquinone gave the *di*-Cl deriv. *o*- $\text{O}_2\text{NC}_6\text{H}_4\text{OMe}$ gave *o*- $\text{ClC}_6\text{H}_4\text{OMe}$, some $\text{Cl}_2\text{C}_6\text{H}_3\text{OH}$ and some*

α -ClC₆H₄OH. These facts indicate that SOCl₂ may be used as a chlorinating agent. Thus C₁₀H₈ gave 1,4-Cl₂C₁₀H₆, identified by oxidation to the corresponding ketone. (PhN:), gave a mixt. of the 2,2'- and the 4,4'-Cl₂ derivs. By the use of suitable conditions (higher temp. or use of a solvent) the side chain may be chlorinated. The reaction may be used to obtain the ClC₆H₄CO₂H which are otherwise hard to prep. The *m*-series do not react as smoothly as do the others. C. J. WEST.

Symmetrical triaminopyridine. HANS MEYER AND ERICH RITTER V. BECK. Univ. Prag. *Monatsh.* 36, 731-49(1915); cf. C. A. 8, 1575.— α, α' -Dichloroisonicotinic acid (A) is best prepd. by the action of POCl₃ upon citrazinic acid in a bomb tube at 200° for 4 hrs. *Methyl ester*, small needles, m. 82°. If a slight excess of N₂H₄·H₂O reacts upon the ester for a few min., α -hydrazo- α' -chloropyridine- γ -carboxylic acid hydrazide results, small needles, m. 226°. If the ester is dissolved in EtOH and treated with N₂H₄·H₂O, α, α' -dichloroisonicotinic acid hydrazide is formed, white needles, m. 184°. A soln. of 5 g. of the hydrazide in 400 cc. H₂O and 30 cc. of 2 N HCl, treated with 3.5 g. NaNO₂, gave the *azide*, m. 89°. The *urethan* results by heating the azide with 20 parts abs. alc. for 2 hrs., needles, m. 132°. α, α' -Dichloro- γ -aminopyridine (B), prepd. by saponifying the urethan with dil. alc. KOH by boiling 3 hrs., needles, m. 176°, sublimes undecompd.; it shows a slight carbylamine reaction, and does not reduce Fehling soln. nor Ag₂O·NH₄OH. When (A) is heated with an excess of NH₄OH for 8 hrs. at 200° in an autoclave, α -amino- α' -chloropyridine- γ -carboxylic acid results, small yellow needles, m. with decompn. If the heating is carried out at 210° after the addition of a little Cu bronze, α, α' -diaminopyridine- γ -carboxylic acid is formed, yellow powder, which does not m. The acid is obtained as colorless needles when the amide is sapond. with KOH. *Methyl ester*, needles, m. 173°. *Hydrochloride*, greenish yellow needles, m. 208° (decompn.). *Amide*, leaflets and stars, m. 256°. *Hydrazide*, needles, m. 260° (decompn.). *Methyl ester dibenzoate*, small needles, m. 312°. With N₂H₄·H₂O this gives the above hydrazide (sapon. of the Bz groups). *Di-*p*-toluenesulfamino- γ -aminopyridine*, prepd. by heating 1 g. (B) with 1.3 g. MeC₆H₄SO₂NH₂ and 0.7 g. Na₂CO₃, together with a little Cu bronze, for 4 hrs. at 180-90°, small needles from dil. alc., does not m. 360°. Upon sapon. with concd. H₂SO₄ for 2 hrs. at 100°, it gives α, γ, α' -triaminopyridine, white needles, m. 185°, sublimes undecompd., is hygroscopic, shows a slight carbylamine reaction, does not reduce Fehling soln., reduces NH₄OH-Ag₂O when heated, and gives an aq. soln. which reacts strongly alkaline. PtCl₄ gives a reddish yellow chloroplatinate, which quickly decomps. in the air.

C. J. WEST.

Substituted benzoylbenzoic acids. ALICE HOFMANN. Univ. Prag. *Monatsh.* 36, 805-24(1915).—*p*-Dichlorobenzoyldichlorobenzoic acid, prepd. by treating a mixt. of 25 g. 3,6-Cl₂C₆H₃(CO)₂O and 250 g. C₆H₄Cl₂, heated to 200°, with 50 g. AlCl₃ and heating 2 hrs., removing the C₆H₄Cl₂ with steam, and extg. with Na₂CO₃, needles from dil. AcOH, m. 205-7°, easily sol. in hot AcOH, alc. and acetone. The *sodium salt* is insol. in an excess of concd. Na₂CO₃. Heated 0.5 hr. with concd. H₂SO₄ at 140° and a few min. at 180°, the acid gives tetrachloroanthraquinone, m. 342° (Schilling, C. A. 7, 2555); a part of the acid was decompd. into C₆H₄Cl₂ and Cl₂C₆H₃CO₂H. *Methyl ester*, prepd. through the chloride, fine needles, m. 145-8°. This pseudo-ester is changed into the *normal methyl ester* by boiling 1 g. with 15 cc. MeOH and 1 cc. concd. H₂SO₄ for 6 hrs., m. 172°. This is also obtained directly from the acid, MeOH and H₂SO₄. Both esters give a colorless soln. with concd. H₂SO₄. *Pentachlorobenzoylbenzoic acid*, prepd. by the action of 25 g. tetrachlorophthalic anhydride, 400 g. PhCl and 50 g. AlCl₃ by boiling 3 hrs., white flakes, m. 165°. The *pseudo ester* did not cryst. The *normal methyl ester* formed an amorphous mass. Heated with concd. H₂SO₄ the acid gave *pentachloroanthraquinone*, m. 192°. *Hexachlorobenzoylbenzoic acid*, from 25 g.

anhydride, 400 g. $C_6H_4Cl_2$ and 50 g. $AlCl_3$, small, hard crystals, m. $238-9^\circ$. The *pseudo methyl ester*, yellowish powder, m. $180-2^\circ$. Normal ester, amorphous. With concd. H_2SO_4 the acid gives *hexachloroanthraquinone*, short yellowish needles which easily sublime as pale citron-yellow needles, m. 298° . *Nitrobenzoyltetrachlorobenzoic acid*, from 20 g. anhydride, 300 cc. $PhNO_2$ and 40 g. $AlCl_3$, m. $242-5^\circ$. It could not be changed into the corresponding anthraquinone. The *pseudo methyl ester* is amorphous. The anhydride does not condense with $O_2NC_6H_3Cl_2$ or $o-CIC_2H_4NO_2$. *Tetrabromobenzoylbenzoic acid*, from 25 g. tetrabromophthalic anhydride, 400 g. $PhBr$ and 50 g. $AlCl_3$, m. $230-2^\circ$; yield, 40 g. Normal methyl ester, glistening plates, m. $108-11^\circ$. *Tetrabromoanthraquinone*, by heating the above acid a very short time with fuming H_2SO_4 (13% SO_3), fine, orange-red, cm.-long needles, m. $200-2^\circ$ (sealed capillary). The Br deriv. is not as resistant to H_2SO_4 as is the Cl deriv. *Pentabromobenzoylbenzoic acid*, m. $228-30^\circ$. Normal methyl ester, m. unsharply above 100° . Pseudo-ester, amorphous, m. $178-83^\circ$. *Pentabromoanthraquinone*, m. $230-40^\circ$ (very poor yield). *Hexabromobenzoylbenzoic acid*, m. $218-9^\circ$. *Hexabromoanthraquinone*, m. $280-5^\circ$. *Tetrabromobenzoyldichlorobenzoic acid*, m. $240-5^\circ$. *Tetraiodobenzoylbenzoic acid*, small yellow crystals, m. $230-1^\circ$.
C. J. WEST.

Chlorination experiments with antimony pentachloride. KARL STEINER. Univ. Prag. *Monatsh.* 36, 825-9 (1915); cf. C. A. 9, 1761.— $SbCl_5$ reacting with Ph_2CO gives *perchlorobenzophenone*, $CO(C_6Cl_5)_2$, needles, m. 318° , and $Cl_3C_6CO_2H$, m. 201° . Benzil gave principally Cl_3C_6H . 1,2-Naphthoquinone and $SbCl_5$ give a small amt. of tetrachlorophthalic acid and probably perchloronaphthoquinone (*Gmelin* 7, 66). $BzOH$ gave a mixt. of products, including some perchlorobenzene. $C_6H_4(CO_2H)_2$ gave a mixt. of Cl derivs. of $BzOH$ and Cl_3C_6 , besides a small amt. of tetrachlorophthalic acid. $BzC_6H_4CO_2H$ gave the same products as $C_6H_4(CO)_2C_6H_4$: perchlorobenzoylbenzoic acid, 1,2,3,5,6,7,8-heptachloroanthraquinone and slight amts. of tetrachlorophthalic acid and Cl_3C_6 . $C_6H_4(CO)_2C_6H_4$ and $SbCl_5$, dild. with an equal vol. of CCl_4 , gave principally 1,4,5,8-tetrachloroanthraquinone.
C. J. WEST.

Cerebronic acid. PERCY BRIGL. Univ. Tübingen. *Z. physiol. Chem.* 95, 161-94 (1915).—This is an attempt to establish the normal constitution of cerebronic acid. *n*-Pentacosane is prepd. in order to compare with the hydrocarbon from cerebronic acid, but the latter could not be prepd. (cf. Levene and West, C. A. 7, 2379). *Ethyl cetylmalonate* (A), b_{14} $238-40^\circ$, m. 22° . *Cetyloctylmalonic acid*, from 19.2 g. (A), 12 g. C_2H_5I and 1.15 g. Na in 70 cc. alc., needles, m. 68° . *Cetyloctylacetic acid*, white powder, m. 52° . Attempts were made to split off CO_2 from this product but no definite product could be obtained. The acid was then changed into the *cetyloctylbromoacetamide*, m. $49-51^\circ$, clears 54° . 6 g. of this product, heated with 1.5 g. Na in 30 cc. abs. alc., for 10 min., gave *cetyl octyl ketone* (*9-pentacosanone*), powder, m. 66° . *Semicarbazone*, m. $39-41^\circ$. When the ketone was changed into the chloride and reduced with HI and red P, *pentacosane* was obtained as white leaflets, m. $55.5-56^\circ$. *Docosyl iodide*, m. $48.5-50^\circ$. *Docosylmalonic acid*, m. 126° . *Tetracosanic acid*, m. 85° . *Behenyl chloride*, m. 40° (Meyer gives $73-75^\circ$; C. A. 7, 3597). *α -Ketotricosylic ethylamide*, $Me(CH_2)_{20}COCONHEt$, prepd. by warming 4 g. $C_{22}H_{44}COCl$ and 1 g. $EtNC$ at 70° and then 100° for 0.5 hr., and decomp. with dil. acetone, m. $91-2^\circ$. Yield, 30%. *Phenylhydrazones*, m. $96-8^\circ$. *α -Hydroxytricosylic ethylamide*, by reduction of the keto acid with $Al-Hg$ in Et_2O , m. $113-5^\circ$. *α -Ketopentacosylic ethylamide*, m. $94-95.5^\circ$. *α -Hydroxypentacosylic ethylamide*, m. $115-7^\circ$. Sapond. with acid, *α -hydroxypentacosylic acid* is obtained, m. $102-4^\circ$. Attempts to racemize the natural cerebronic acid gave a product m. $97-100^\circ$ instead of 84° as given by Levene. B. therefore decides to call the low melting acid *neuro acid*, while the higher melting cerebronic acid, m. $100-1^\circ$, is *n*-hydroxypentacosylic acid.
C. J. WEST.

Nuclein metabolism. III. High molecular, crystalline decomposition products of yeast nucleic acid. S. J. THANNHAUSER AND G. DORFMÜLLER. München. *Z. physiol. Chem.* 95, 259-62(1915); cf. *C. A.* 8, 3580.—The triphosphonucleic acid, $C_{22}H_{41}O_{22}N_{15}P_3$, earlier obtained by the digestion of yeast nucleic acid with human duodenal juice, has now been obtained by hydrolysis with NH_3 under very little pressure. 50 g. acid in 40 cc. 25% NH_3 and 210 cc. H_2O were heated 1.75 hrs. at 120-25° in an autoclave. The soln. was poured into 800 cc. alc., the grayish white ppt. filtered off, taken up in cold H_2O and the acid pptd. from the hot soln. by hot $Pb(OAc)_2$. The ppt. is decompd. by H_2S , the filtrate concd. at 30° to 40 cc., and alc. added as long as a ppt. forms. The ppt. was again taken up in H_2O , the soln. concd. to 30 cc. and poured into 400 cc. of 96% alc. Yield, 2-3 g. 2 g. in 25 cc. H_2O were treated with 4 g. brucine in 8 cc. b. alc., giving 2 g. *brucine salt*, which was purified through the Ag salt, m. 205°. From the mother liquors, as above, a second *brucine salt* was obtained, m. 182-3°, containing C 58.3, H 5.89, N 7.6, P 2.98%. C. J. WEST.

β -Methylanthracene and β -anthraquinonecarboxylic acid. I. OTTO FISCHER AND KURT REINKOBER. Univ. Erlangen. *J. prakt. Chem.* 92, 49-54(1915).—When β -methylanthracene (a) is subjected to the action of Cl in various solvents, mixts. of halogen derivs. are invariably obtained in every case; in 100 parts dry CS_2 satd. cold with Cl, a mixt. of *penta-* and *hexachloromethylanthracene* seps., light yellow prisms from 70% alc., m. 191°; satd. in $CHCl_3$ with Cl, the product, which is chiefly the *hexachloro derivative*, seps. in needles from AcOH, shows a blue fluorescence in soln. and m. (not sharply) 193°; treated with Cl in 20-30 parts CS_2 until no more HCl is evolved, the product, needles from AcOH, m. 220°, analyzes for a mixt. of *hepta-* and *deca-chloro derivatives*; suspended in C_6H_6 and treated with Cl until the soln. is clear, it gives a cryst. product with a Cl content lying between that of the *mono-* and *dichloro derivatives*. Better results are obtained with Br. *meso-Dibromo- β -methylanthracene* (b), [cf. Fischer, *Ber.* 7, 1196(1874); Liebermann, *Ann.* 212, 35(1882)] dissolves in Br with the evolution of HBr and the formation of *pentabromo- β -methylanthracene*, light yellow prisms, m. 300° (decompn.). (b) is slowly converted by CrO_3 in AcOH into β -anthraquinonecarboxylic acid (c), but toward reducing agents is very stable; it is thus recovered unaltered after passing HI into the boiling AcOH soln. for 2 hrs. (a) is likewise stable under the same treatment, but is reduced by Na in boiling AmOH to *meso-dihydro- β -methylanthracene*, needles from 70% alc. It m. 51°, is volatile with steam and becomes brown in the light and air. (a) is very resistant to the action of HNO_3 . Thus to produce a satisfactory yield of β -methylanthraquinone from (a), 1 part (a) must be boiled with 2 parts HNO_3 , d. 1.48, for 6 hrs.; practically no CO_2H acid or NO_2 compd. are formed under these conditions. To convert (a) into (c), it is necessary to heat with 3 parts HNO_3 , d. 1.5, and 2 parts H_2O at 170° for 8-10 hrs. under pressure [cf. Liebermann, *Ber.* 17, 888(1884)]. *Ammonium salt* of (c), needles from dil. NH_4OH , which revert to the free acid and NH_3 at 100-110°; *sodium salt*, $C_{14}H_7O_4Na \cdot H_2O$, prisms from H_2O ; *barium salt*, $C_{14}H_7O_4Ba \cdot 3H_2O$, cryst. ppt.; *pyridine salt*, $C_{17}H_{11}O_4N$, loses C_4H_4N at 100°; *quinoline salt*, $C_{24}H_{18}O_4N$, needles.

NORMAN A. SHEPARD.

The behavior of *p*-dimethylamino-*o*-benzoylbenzoic acid and related substances toward nitrous acid. OTTO FISCHER AND HANS LOEWZ. *J. prakt. Chem.* 92, 54-60 (1915).—When *p*-dimethylamino-*o*-benzoylbenzoic acid, $HO_2CC_6H_4COC_6H_4NMe_2$ (a), *p*-dimethylamino-*o*-benzylbenzoic acid, $HO_2CC_6H_4CH_2C_6H_4NMe_2$ (b), and *p*-dimethylanilino-phthalide, $O.CO.C_6H_4.CHC_6H_4NMe_2$ (c), are treated with HNO_2 , the products

are not NO (cf. Limpricht, *Ann.* 300, 228(1898)), but NO_2 compds. 30 g. (a) in 150 g. dil. HCl treated ice cold with 7.7 g. $NaNO_2$ in 50 g. H_2O , filtered from the (a)-HCl

which seps., allowed to stand 6 hrs. in ice water and neutralized with Na_2CO_3 , gives *mononitrodimethylaminobenzoylbenzoic acid*, pointed yellow prisms from Et_2O , m. 164° , which does not give the Liebermann NO reaction and is identical with the NO_2 compd. obtained by L. from (a) with H_2SO_4 and HNO_3 (cf. *Ann.* 307, 308). (b), previously prepd. by L. from (a) in NH_4OH with Zn dust and by Haller and Guyot (cf. *Compt. rend.* 126, 125) by reduction of (a) with Zn in dil. NaOH , is obtained more smoothly by reduction with Zn in acid soln., using 10 g. (a) in 200–300 g. glacial AcOH , 1 cc. fuming H_2SO_4 (30% SO_3) and an excess of Zn dust; yield, about 9 g. 2 g. (b) in 15 g. 40% HCl and 180 g. H_2O treated ice-cold with 1.5 g. NaNO_2 in 20 g. H_2O , gives 0.5 g. of a hydrochloride which dissociates in H_2O , giving a product sepg. in small orange-yellow prisms from C_6H_6 , m. about 180° . This product was not isolated by L. under the same conditions. The mother liquor from this hydrochloride, on neutralization with Na_2CO_3 , seps. 1.5 g. *nitrodimethylaminobenzoylbenzoic acid*, long, pointed prisms from dild. MeOH , m. $133-4^\circ$, which was erroneously described by L. as the NO compd. (c) (cf. Haller and Guyot, *Bull. soc. chim.* [3] 19, 830) is obtained in 70% yield on reduction of (a) in dil. NaOH with Na-Hg, neutralizing from time to time with AcOH ; reduced according to L.'s directions, a mixt. of *nitrodimethylanilinophthalide* (not the NO deriv.), orange-red leaves, m. 157° , sol. in HCl and pptd. by Na_2CO_3 or NH_3 , and *nitrosomonomethylanilinophthalide*, light yellow needles from MeOH , m. 175° , is obtained.

NORMAN A. SHEPARD.

The action of *p*-nitroso bases on hydrazines. OTTO FISCHER AND W. JOHANNES. *J. prakt. Chem.* 92, 60–73 (1915).—When 3 mols. $\text{EtNHC}_6\text{H}_4\text{NO} \cdot \text{HCl}$ (a) is treated in H_2O at 0° with 2 mols. $\text{PhNHNH}_2 \cdot \text{AcOH}$ (b) and allowed to stand 2 hrs., *p*-ethylaminodiazooxyaminobenzene (c) seps. in yellow leaves; pptd. from warm alc. by H_2O at $30-40^\circ$, or from C_6H_6 by petr. ether, it explodes $122-3^\circ$; boiled with dil. acids or alkalis, it decomps. into N, PhOH , $\text{EtNHC}_6\text{H}_4\text{NO}$ and a resin; dissolved in cold CHCl_3 , (a) seps. [cf. Fischer and Wacker, *Ber.* 21, 2609 (1888); 22, 622 (1889)]; the picrate of (c) seps. in small, yellow prisms. (c), and the similar substances described below, may be repre-

 sented by two structures, $\text{R}_2\text{NC}_6\text{H}_4\text{N}(\text{:O})\text{:NNRPh}$ and $\text{R}_2\text{NC}_6\text{H}_4\text{N} \cdot \text{N} \cdot \text{NRPh}$, of which the latter is preferred, for some of these substances are volatile without decompn., which would hardly be expected were a pentavalent N present. *p*-Ethylaminodiazooxymethylaminobenzene (d) is formed when (a) is treated with $\text{PhNMeNH}_2 \cdot \text{AcOH}$ (e); bright yellow needles from alc., m. 97° , which explode when heated rapidly. Substituted products of this type are more stable than (c); (d) does not react with CHCl_3 , though dil. H_2SO_4 decomps. it with the evolution of N. In exactly the same manner the following were obtained: *p*-methylaminodiazooxymethylaminobenzene, from *p*- $\text{MeNH} \cdot \text{C}_6\text{H}_4\text{NO} \cdot \text{HCl}$ (f) and (e), yellow prisms from luke-warm dil. alc., m. $98-100^\circ$; *p*-dimethylaminodiazooxyphenylaminobenzene, from $\text{Me}_2\text{NC}_6\text{H}_4\text{NO} \cdot \text{HCl}$ (g) and $\text{Ph}_2\text{N} \cdot \text{NH}_2$ (h) in dil. AcOH , yellow needles from alc., m. 150° (decompn.); *p*-methylaminodiazooxyphenylaminobenzene from (f) and (h), yellow needles, m. 167° ; *p*-dimethylaminodiazooxyamino-*p*-bromobenzene, from (g) and *p*- $\text{BrC}_6\text{H}_4\text{NHNH}_2$ in dil. AcOH , yellow prisms, m. 128° (decompn.), which decomp. on boiling with dil. H_2SO_4 into N, PhBr , $\text{Me}_2\text{NC}_6\text{H}_4\text{NH}_2$ and a resin; *p*-dimethylaminodiazooxy- α -aminonaphthalene, from (g) and $\alpha\text{-C}_{10}\text{H}_7\text{NHNH}_2$, greenish yellow, unstable, decomp. on the filter in spite of cooling; *p*-dimethylaminodiazooxy- β -aminonaphthalene, yellow needles exploding on heating. *p*-Dimethylaminodiazooxymethylaminobenzene (i), previously prepd. by F. and J., forms neither a stable hydrochloride nor hydrobromide, but gives a stable picrate, small yellow prisms, and a quaternary salt with MeI , clusters of yellow needles from abs. alc., m. 147° ; when (i) in glacial AcOH is reduced at 0° with Zn dust, it decomp. chiefly into *p*- $\text{Me}_2\text{NC}_6\text{H}_4\text{NH}_2$ and PhNMeNH_2 , with a little NH_3 and MeNHPH .

Diazooxymethylaminobenzene (cf. *Ber.* 22, 622) forms a *picrate*, yellow needles, de-

comp. 114°. *p*-Dimethylaminodiazooxyurea, $p\text{-Me}_2\text{NC}_6\text{H}_4\text{N}-\text{N}(\text{O})\text{NHCONH}_2$, is obtained from $\text{Me}_2\text{NC}_6\text{H}_4\text{NO}$ and $\text{NH}_2\text{CONHNH}_2$ (j) in AcOH; groups of yellow-green needles from glacial AcOH or $\text{C}_6\text{H}_5\text{N}$, which explode 181°. From $p\text{-NH}_2\text{C}_6\text{H}_4\text{NO}$ and (j), under the same conditions, *p*-aminodiazooxyurea, yellow needles, m. 220° (decompn.), is formed.

NORMAN A. SHEPARD.

A misleading report on formose. OSCAR LOEW. *J. prakt. Chem.* 92, 133-5 (1915).—The 11th edition of Richter's "Chemie der Kohlenstoffverbindungen" ascribes the synthesis of the first sugar-like substance to Butlerow, who prepd. "methylenitan" in 1861; it further states that "in an analogous manner," Loew obtained formose from $(\text{CH}_2\text{O})_6$ and $\text{Ca}(\text{OH})_2$. L. objects to this statement, pointing out that B.'s methylenitan was a mixt. of transformation products of formose and actually contained only 20% or less of real sugars, since it was prepared from $(\text{CH}_2\text{O})_6$ and boiling $\text{Ca}(\text{OH})_2$. Furthermore, L.'s conditions were not "analogous" to B.'s, for L. worked with 3-4% aq. CH_2O at room temp. and whereas B.'s product was a brown smeary syrup with a burned odor and bitter taste, and analyzed very poorly, L.'s product was colorless, sweet, and analyzed exactly for $\text{C}_n\text{H}_{2n}\text{O}_n$ (cf. *J. prakt. Chem.* 33, 342(1886)). L. also objects to the statement that he used MgO in the prepn. of the fermentable methose, for he actually employed $\text{MgSO}_4 + \text{PbO}$, and MgO, even at 100°, is not a condensing agent. L. claims the distinction of having been the first investigator to show that really sugar-like substances can be obtained from CH_2O , and introduces very interesting excerpts from letters of congratulation received from Nencki, E. von Meyer, R. Maly and E. Schulze at the time of the prepn. of formose to prove his point.

NORMAN A. SHEPARD.

Alleged existence of an optically active benzaldehyde. G. BRÉDIG AND M. MINARFF. Karlsruhe. *Chem. Ztg.* 39, 73.—The so-called optically active PhCHO , which Erlenmeyer (cf. *Chem. Ztg.* 1911, 1095) thought to have obtained by boiling BzH (a) in alc. with $[\text{CH}(\text{OH})\text{CO}_2\text{H}]_2$ (b) is a mixt. of ordinary (a) with a small amt. of a compd. of (a) + (b), to which compd. the optical activity is due. This impurity can be sapond. by boiling with dil. H_2SO_4 , which leaves the oil entirely inactive; or the ordinary BzH , which constitutes approx. 90% of the oil, can be sepd. as the bisulfite addition product, leaving an active residue of (a) + (b) ($\alpha_D -40$). N. A. S.

The velocity of nitration of benzene and of some of its derivatives. J. P. WIBAUT. Amsterdam. *Rec. trav. chim.* 34, 241-58(1915).—In studies on substitution in the C_6H_6 ring Holleman attributed great importance to the velocity of substitution and to the influence that substituents already present exercise on this velocity and the ideas put forward by him have been of great value. But the actual knowledge of this velocity is small in amt. Martinsen (*Z. physik. Chem.* 50, 385(1905); also *C. A.* 1, 2763) detd. the velocity of nitration in concd. H_2SO_4 and found that in this medium it is often very great. W. wished to det. the relative velocity of nitration of PhMe and PhCl . Since it seemed improbable that a solvent could be found in which this nitration would take place slowly an indirect method was used. If one adds to an equimol. mixt. of PhMe and of PhCl a small amt. Δx of HNO_3 , Δx_1 nitrotoluenes and Δx_2 nitrochlorotoluenes are formed. Although all of the HNO_3 is not consumed, Δx_1 and Δx_2 ought to be in direct ratio to the velocity of nitration of PhMe and PhCl , and thus $\Delta x_1/\Delta x_2 = k_1/k_2$, where k_1 and k_2 are the corresponding consts. When additional amts. of HNO_3 are added the calcn. becomes difficult since the mol. concns. of PhMe and PhCl are no longer equal. So that by varying the amt. of HNO_3 used with an equimol. mixt. values for the amt. of nitrotoluenes and nitrochlorobenzenes which have no sim-

ple relationship to each other are obtained. But as the amt. of HNO_3 is decreased the values obtained will correspond more and more closely to k_1/k_2 . The amt. of HNO_3 was varied and added drop by drop to an equimol. mixt., the temp. was kept at 0° and the mixt. was strongly agitated. The mixt. was then treated with $\text{Fe} + \text{H}_2\text{SO}_4$ in aq. suspension in order to reduce the NO_2 to NH_3 , then treated with excess of H_2SO_4 and the unchanged PhMe and PhCl distd. off, the liquid was made alk. and distd. with steam, the distillate was satd. with NaCl and extd. with Et_2O in order to obtain the mixt. of toluidines and chloroanilines. By detg. the Cl in the mixt. the mol. ratio of the 2 types of compds. could be detd. but ratios found were discordant, owing perhaps to the fact that 2 liquid layers are formed during the nitration. Other nitrations were therefore done in Ac_2O and C_6H_6 was used instead of PhMe . An equimol. mixt. of $\text{C}_6\text{H}_6 + \text{PhCl}$ was dild. with Ac_2O and insufficient HNO_3 dild. with Ac_2O was added and the mixt. allowed to stand at room temp. for some days. The results seem to indicate that C_6H_6 is nitrated 17 times as fast as PhCl , but this was later found to be wrong. The mixts. of C_6H_6 and PhX were nitrated at 25° , but the PhMe at 0° . A weighed amt. of the compd. to be nitrated was placed in a small flask with 50–75 cc. Ac_2O . The weighed amt. of HNO_3 was added to 50 cc. Ac_2O with cooling. After standing in the thermostat some time the latter mixt. was poured into the former, and after some mins. in the thermostat the first sample was removed and this was taken as the beginning of the expt. From time to time 10 cc. were removed and added to 50 cc. NaOH soln. (d. 1.24) and converted into $\text{NaNO}_3 + \text{NaOAc}$, the liquid was extd. with C_6H_6 in order to remove PhNO_2 (which could be reduced to PhNH_2 and give NH_3 by hydrolysis), the liquid was placed in a 600 cc. Erlenmeyer, 30 cc. more NaOH added, then 3 g. Devarda's alloy and boiled under a condenser arranged to catch the evolved NH_3 in 0.2 N H_2SO_4 . The error may amt. to 1–2% of the HNO_3 used. The concn. of the reacting substances was $\approx 0.5 N$ for the C_6H_6 or deriv. and $\approx 0.75 N$ for the HNO_3 . The exptl. data are given in tables where t is the time, c the concn. of the HNO_3 , and k the velocity const. calcd. from the bimol. formula. In one expt. with C_6H_6 the values of t , c and k , resp., are 0, 0.7174 N , —; 44 mins., 0.6837, 0.0025; 102, 0.6505, 0.0023; 221, 0.5879, 0.0023; 347, 0.5331, 0.0024; 433, 0.4972, 0.0026; 558, 0.4336, 0.0032; av. for k , 0.00255. The mean results obtained for k were as follows: C_6H_6 at 25° , 0.0025; PhCl at 25° , 0.0020; PhBr at 25° , 0.0013; PhMe at 0° , 0.0080.

Theoretical considerations. Although the expts. described above are very incomplete from the point of view of a dynamic study of nitration, nevertheless some very interesting conclusions can be drawn about substitution in the C_6H_5 ring. The relative decreasing order of velocity of substitution is $\text{PhMe} > \text{C}_6\text{H}_6 > \text{PhCl} > \text{PhBr}$ for the introduction of a 2nd substituent. In considering the introduction of a 3rd substituent in a disubstituted benzene Holleman (*Die Einführung*, etc., p. 460) has indicated 2 factors that det. this relative velocity: (1) in the introduction of C in $\text{C}_6\text{H}_4\text{AB}$ the 1st factor is the ratio of the velocity with which the introduction of C in PhA and PhB takes place and the 2nd is the proportion in which $\text{C}_6\text{H}_4\text{AC}$ and $\text{C}_6\text{H}_4\text{BC}$ are formed in each case. From exptl. facts he deduced that the order of decreasing velocity for groups directing to p -o-positions is $\text{OH} > \text{NH}_2 > \text{I} > \text{Cl} > \text{Br} > \text{CH}_3$ and for groups directing to the m -position is $\text{CO}_2\text{H} > \text{SO}_3\text{H} > \text{NO}_2$. W. has shown (*C. A.* 8, 1268) that the velocity of nitration caused by Cl is to the velocity of nitration caused by Me as 1:1.475. Holleman (*C. A.* 9, 2384) calcd. the velocity of nitration of dihalogenbenzenes $\text{Cl}:\text{Br} = 1:0.88$ and $\text{Cl}:\text{I} = 1:1.84$. But these relations were deduced for the cases in which both groups are present in the same ring. The influence of groups on the total velocity of introduction of a 2nd substituent does not follow these ratios. For if it did the velocity of nitration of PhCl would be 1.5 times greater than that of PhMe which was not found above. From the expts. of Martinsen (*C. A.* 1, 2763) and Klemenc (*C. A.* 8, 1105) it is further argued that the influence of groups on the

total velocity of substitution is not bound by a direct proportion to the influence that 2 groups simultaneously present exercise on the relative velocity with which the H atoms of the ring react. The rule of Holleman, which consists in the possibility of systematizing in a rational and general manner the phenomena of the introduction of a 3rd substituent and of prophesying unknown cases, does not lose its value as a result of this work. In comparing the results of Martinsen with those of W. the great influence of the medium on the velocity of nitration is evident. In H_2SO_4 the velocity of nitration is much greater than in Ac_2O . M. found for k_{25}^0 in PhNO_2 1.5, $o\text{-ClC}_6\text{H}_4\text{NO}_2$ 7.15, p - 0.18, m - 0.39; for nitrotoluenes $k_{25}^0 = \infty$, 4,6-dinitro- m -xylene, $k = 0.004$, 2,4-dinitromesitylene, $k = 6.65$. He deduced from a comparison of the chloronitrobenzenes with PhNO_2 that the role of Cl is sometimes accelerating, sometimes retarding, depending on the position of the Cl in the ring. In comparing $(\text{NO}_2)_2\text{C}_6\text{H}_2\text{Me}$ derivs. with the nitrotoluenes the accelerating effect of Me is strikingly evident. Thus it seems that the influence of substituents on the total velocity of nitration is nearly the same whether there is only 1 substituent in the C_6H_5 ring or whether several are simultaneously present. W. expects to continue these expts. E. J. WITZEMANN.

The types of substitution. Remarks on the subject of the preceding communication of J. P. Wibaut. A. F. HOLLEMAN. Univ. Amsterdam. *Rec. trav. chim.* 34, 259-60(1915).—Wibaut showed (cf. preceding abstr.) that the velocity of substitution in PhMe is greater than in PhCl and in the latter less than in C_6H_6 , which confirms the results of v. d. Linden (*Verslag. Akad. Wetenschappen* 745(1911)) and of Olivier (*C. A.* 9, 442) and which necessitates a slight change in the hypothesis of H. and Böeseken (*Die directe Einführung*, etc., p. 475(1909)). H. and B. suggested that substituents causing the substitution to p,o -positions have such an action on the conjugated system of double bonds 1, 2, 3, 4 that the replacement of H atoms 2 and 4 is accelerated, while the double bond 5,6, not being in direct relation with X, does not have any influence. The results obtained by W. show that the introduction of a substituent may modify considerably the total velocity with which the remaining 5 H atoms are able to be substituted, but nothing opposes the idea that there remains notwithstanding a great difference between the velocity with which H atoms 2 and 4 are substituted compared with 3. With this modification the hypothesis may be retained unchanged. Although the simultaneous presence of 2 groups in the ring modifies the total velocities of substitution the ratio in which the isomers are formed under the influence of each of the groups must remain practically unchanged, since the relative amts. of the isomers $\text{C}_6\text{H}_3\text{ABC}$ that are formed when one introduces C in $\text{C}_6\text{H}_4\text{AB}$ may be calcd. on the basis of the relative amts. of the isomers formed by introducing C in Ph A and Ph B .

E. J. WITZEMANN.

The nitration of chloroethylbenzene, $\text{C}_6\text{H}_5\text{CH}_2\text{CH}_2\text{Cl}$. A. F. HOLLEMAN. Univ. Amsterdam. *Rec. trav. chim.* 34, 261-4(1915).—H. (*C. A.* 8, 1268) in nitrating PhMe and its Cl derivs. showed that in nitrating PhCH_2Cl at $20\text{--}30^\circ$, 40.9% of the o -isomer was formed. v. Braun (*C. A.* 6, 2605; 8, 123) found that in nitrating $\text{PhCH}_2\text{CH}_2\text{Cl}$ the $p\text{-NO}_2\text{C}_6\text{H}_4\text{CH}_2\text{CH}_2\text{Cl}$ (a) was formed exclusively. H. doubted this result because (1) the oily nitration product sepd. on cooling $25\text{--}30^\circ$ of (a), m. 49° , but the rest remained liquid. (2) v. B. considered that this liquid part is essentially pure (a) but contains a small amt. of impurity and hence does not cryst. Now the numerous binary and ternary f. p. curves show that small amts. of impurity cause small lowerings in the f. p., while here there is a lowering of at least 30° . (3) v. B.'s results with the liquid part show that some (a) was present but do not show that it was nearly pure (a). (4) v. B. worked at -15° and H. nitrated PhCH_2Cl at $20\text{--}30^\circ$ but this difference in temp. is not sufficient to account for so large a difference in the result especially since a difference of 90° in the temp. of nitration of PhMe does not change the % of the o -deriv.

(55.6% at -30° and 57.5% at 60°). v. B. sent 10 g. of the liquid residue from the crystn. of (a) to H. ($n = 1.5529$ at 52.5° , Cl 19.2%, calcd. 19.1% for (a)). This was dissolved in 30 g. glacial AcOH, 2 g. anhydrous AcONa was added and the mixt. boiled for some time (some tarring took place). The product was oxidized with KMnO_4 in acid soln., which gave some $p\text{-O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ and probably a little of the *o*-acid. H. repeated v. B.'s nitration and oxidized the product with KMnO_4 in alk. soln. since the $o\text{-O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ is more stable than in acid soln. 13 g. of the product in 0.5 l. $\text{H}_2\text{O} + 42$ cc. 10% KOH were boiled and 39.5 g. KMnO_4 in soln. was slowly added, the MnO_2 was filtered off, washed 3 times with 0.5 l. H_2O and the entire filtrate cond. to 1 l. The soln. was extd. with Et_2O to remove tar and acidified. 7 g. (a) were pptd. and filtered off. The filtrate was extd. with Et_2O which gave a residue of 3 g. This was converted into the Ba salt and the method of sepn. previously described (*l. c.*) was used. 1 g. of $o\text{-O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ m. 146° , identical with the same compd. obtained from other sources, was sepd. It is probable that the original nitration product contains about 30% of the *o*-deriv. Some crystals resembling $m\text{-O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ were sepd. which gives support to the idea that some $m\text{-O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{CH}_2\text{Cl}$ is also present in the nitration product.

E. J. WITZEMANN.

Nitration of *p*-bromotoluene. A. F. HOLLEMAN. Univ. Amsterdam. *Rec. trav. chim.* 34, 283-8 (1915).—The nitration of $p\text{-BrC}_6\text{H}_4\text{Me}$ studied by Wroblewsky (*Ann.* 168, 176 (1873)) and Huebner and Roos (*Ber.* 6, 799 (1873)) has been repeated in order to det. if the 2 isomers 1,2,4- (a) and 1,3,4- $\text{MeC}_6\text{H}_3(\text{NO}_2)\text{Br}$ (b) are formed in the calcd. amts. The data necessary are (1) the quant. ratio of the nitrotoluenes formed in the nitration of PhMe ; (2) the ratio of isomeric bromonitrobenzenes formed in the nitration of PhBr ; (3) the ratio of velocities of substitution that Br and Me cause, which is calcd. from the ratio of $\text{Cl}:\text{Me} = 1.475$ and $\text{Br}:\text{Cl} = 0.88$ as $\text{Br}:\text{Me} = 1.3$. From these data the calcd. ratio of (a):(b) = 52.4%. The nitration of $p\text{-BrC}_6\text{H}_4\text{Me}$ cannot be executed sharply. A small amt. of accessory product is formed which renders the analysis difficult so that the results are only approx. *p*-Toluidine was dissolved in 20 times its wt. of concd. H_2SO_4 and nitrated according to Noeltling and Collin (*Ber.* 17, 263 (1884)) and the NO_2 deriv. diazotized according to Erdmann (*Ann.* 272, 145 (1893)) gave (a) m. 45.5° , almost white, $n_{40} = 1.5750$; heated 24 hrs. at 110° with 0.33 *N* MeONa it liberated a little Br, but 24 hrs. at 170° with satd. $\text{NH}_3\text{-EtOH}$ was almost without effect. *p*-Acetotoluidide nitrated according to Gattermann (*Ber.* 18, 1483 (1885)) gave a NO_2 deriv. which was sapond. and gave a nitro-*p*-toluidine, m. 114° . This diazotized according to Erdmann gave impure (b) which crystd. from MeOH and distd. *in vacuo* gave pure (b), m. 33° , $n_{40} = 1.5682$; heated with MeONa as above, the Br is completely removed. $\text{NH}_3\text{-EtOH}$ leaves a part unchanged. The f. p. curve of (a) + (b) drops from 43.6° to below 15.8° at 36.3 mol. % (a) and rises to 31.0° at 100 mol. % (b). A series of nitrations was carried out without obtaining an entirely clean result, but the following facts were always observed: (1) a little Br is eliminated from the ring; (2) a nitrophenol-like substance is always formed which gives intensely red salts with alkalis and which can be removed by agitating the C_6H_6 soln. of the nitration product with alkalis; (3) a small amt. of a product having a higher Br content than (a) or (b) is formed. 20 cc. HNO_3 (d. 1.52) cooled with ice and treated with 2 portions of 10 g. of $p\text{-BrC}_6\text{H}_4\text{Me}$ were poured on ice (5 min. required). The product was dissolved in C_6H_6 , washed free from acid, and agitated some hrs. with very dil. KOH, washed again with H_2O , dried with Na_2SO_4 , the C_6H_6 distd. off and the residue distd. *in vacuo*; almost no tar is formed in successful expts. Crystals of (a) sep. The f. p. was 20.2° , which corresponds to 56.3% (a) and 43.7% (b). The eutectic point was found at 5.3° instead of 9.5° on adding a known amt. of (b), showing that a 3rd compd. is present. On heating a mixt. of (a) + (b) with MeONa 24 hrs. at 110° 103.7% of

the amt. of Br corresponding to the (b) used was found, due to the decompn. of some of (a). Treating the product of nitration in the same way 41.5% (b) were found, which agrees well with the % of (b) found from the f. p. The results for the isomers (a) and (b) coincide approx. with the calcd. values.

The polymerization of isoprene under the influence of an aluminium-mercury couple. J. BÖRSEKEN AND J. NOORDUIJN. Delft. *Rec. trav. chim.* 34, 265-71 (1915). —Expts. on the condensation of C_6H_6 and its derivs. with C_6H_6 in the presence of an Al-Hg couple (C. A. 8, 1270) showed that the initial reaction is an addition of C_6H_6 at the double bond: $-C:C- + C_6H_6 \rightarrow -CPhCH-$. The polymerization of C_2H_4 does not take place under these conditions. A mixt. of $C_2H_4 + HCl$ gas passed over $AlCl_3$ at 50° gives a satd. condensation product free from Cl. $PhCH:CH_2$ in a C_6H_6 soln. of the catalyzer combines only with itself: thus the Ph group in C_2H_4 favors polymerization. Since this polymerization is probably due to the presence of adjoining systems of unsatd. bonds it was thought that isoprene ought also to polymerize in C_6H_6 under the influence of a catalyzer. 2 kinds of condensation products were obtained: (1) sol. in C_6H_6 , Et_2O , $CHCl_3$, etc., is a mixt. of polymers of isoprene of high mol. wt. since a 5% soln. in C_6H_6 did not elevate the b. p.; very little viscous; cannot be vulcanized (2) more insol. products with otherwise similar properties. These products are much more satd. than caoutchouc. In the method of Harries and Gottlob (C. A. 5, 3583) of prepg. isoprene by passing vapors of carvene along a Pt wire heated dull red with the electric current, after some days the wire becomes coated with C and the reaction slows up, showing that the Pt acts partly as a catalyzer and that it is poisoned by the C. The Hg-Al catalyzer was prepd. by pouring 0.2 g. powdered Al into a dry C_6H_6 soln. of 3 g. $HgCl_2$ and warming gently; a dark brown liquid was formed. After cooling 10 g. isoprene in 40 cc. C_6H_6 were added and the mixt. warmed 0.5 hr. on the H_2O bath. After standing 24 hrs. the amorphous powder sepd. was filtered off. The filtrate was washed, dried, and fractionated, leaving a nearly white resin, the odor of isoprene was absent; while warm it could be drawn into threads, but on cooling it turned into a hard, easily powdered mass. When carried out in a H_2 atm. the same result was obtained. The powdered material was placed in a desiccator over P_2O_5 until const. in wt. This showed C:H as 5:8.1 on analysis and may be an impure polyisoprene. The polymer adsorbed some Al, Hg and Cl as was shown by special tests. By detg. the I absorption it was found that the unsatn. is diminished $\frac{1}{4}$. An amorphous yellow Br deriv., $(C_6H_6)_4Br_2$, was obtained by brominating in CCl_4 soln. Attempts to hydrogenate the product by Willstätter's method with active Pt in ligroin soln. failed. The viscosity detns. are described.

E. J. WITZEMANN.

The influence of some polyhydroxylated substances on the electrical conductivity of boric acid. J. BÖRSEKEN with J. D. RUYS AND K. BRACKMANN. Delft. *Rec. trav. chim.* 34, 272-8 (1915). —1,2- $C_{10}H_8(OH)_2$ was obtained from 150 g. β -naphthol through α,β - $C_{10}H_8(NO)OH$, reduced to α,β - $C_{10}H_8(NH_2)OH$, oxidized to 134 g. β -naphthoquinone (Lagodzinsky, Hardine, *Ber.* 27, 3075 (1893)), reduced with SO_2 (*Z. angew. Chem.* 1897, 24) and recrystd. from aq. SO_2 . The conductivity was detd. as in preceding papers (C. A. 6, 623; 9, 1766) in $\frac{1}{4}$ and $\frac{1}{32}$ (satd.) M solns. of (a) to which 0.5 M solns. of H_3BO_3 were added. (a) exercises a marked positive action ($k = 84.6$ and 112.2 instead of 32.0 and 47.1 as calcd.) comparable to that of o - $C_6H_4(OH)_2$. 3,4- $(HO)_2C_6H_3CO_2H$ was recrystd. several times from conductivity H_2O and conductivity detns. were made in $\frac{1}{32}$, $\frac{1}{16}$ and $\frac{1}{8}$ M concns. in the presence and absence of 0.5 M H_3BO_3 . The excess conductivity for the mixts. was 68.7, 64.9 and 119.3, resp. Gallic acid in the same concns. showed an excess conductivity for the mixt. of 41.1, 83.2, 181.6, resp. The influence of the 2 preceding is positive and of the same order as o - $C_6H_4(OH)_2$ and pyrogallol. It is not probable that CO_2H *m*- or *p*- to OH groups plays any important role. It

may be that the complex formed between the OH's and the H_3BO_3 is similar to that of the phenols named. 3,5-Dinitropyrocatechol (*b*) (Nietski and Moll, *Ber.* 26, 2183 (1893)) is so little sol. that only a $1/300$ *M* soln. could be obtained. This soln. mixed with $1/64$, $1/32$, $1/16$, $1/8$, $1/4$, $1/2$ *M* H_3BO_3 solns. showed an excess conductivity of 16.3, 26.2, 45.1, 76.8, 116.4, 122.3, resp. 4-Nitroresorcinol (*c*) in $1/128$ and $1/256$ *M* soln. showed a feeble negative influence mixed with $1/64$ to $1/2$ *M* solns. of H_3BO_3 . The contrast between *o*- and *m*- $C_6H_4(OH)_2$ in their influence on the conductivity of H_3BO_3 is not changed in principle but is increased by the introduction of NO_2 groups. The results show that the positive influence of the NO_2 group on the acidity of the phenol group as observed in *o*- and *p*- $O_2NC_6H_4OH$ disappears when 2 OH groups are present simultaneously in these positions. 1,2,4- $C_6H_3(OH)_3$ (*d*) was prepd. from quinone (Thiele, *Ber.* 31, 1248 (1898)). The aq. solns. are unstable and were mixed with the H_3BO_3 each in $1/2$ *M* soln. and the conductivity detd. at once. The mixt. showed a depression in the conductivity even though 2 OH's were *o*- to each other. This seems to be an exception to the rule that *o*-(HO) $_2$ derivs. of the aromatic series increase the conductivity of H_3BO_3 . The conductivity of (*d*) itself is about 20 times as great as that of pyrogallol or phloroglucinol.

E. J. WITZEMANN.

The influence of some polyphenols on the electric conductivity of phosphoric acid. J. BÖSEKEN AND K. BRACKMANN. Delft. *Rec. trav. chim.* 34, 279-82 (1915).— H_3PO_4 in having 3 OH groups bound to P is similar to H_3BO_3 . B. and B. have therefore investigated the influence of some polyphenols on the conductivity of H_3PO_4 to see if its effects are similar, *i. e.*, the pyrocatechol and pyrogallol ought to increase its conductivity, while *m*- and *p*- $C_6H_4(OH)_2$ ought to diminish it. It was found, however, that all four, as well as phloroglucinol, diminish the conductivity without any marked difference in behavior. The *o*-phenols do not form complex acids stronger than the components. The detns. were made in the same way as in the case of H_3BO_3 (cf. preceding abstr.) at 25°. The phenols were recrystd. from C_6H_6 or H_2O until the conductivity no longer changed. The phenols in soln. of 1, $1/2$, $1/4$, $1/8$, $1/16$, $1/32$, $1/64$ mol. % were mixed with H_3PO_4 solns. of $1/8$, $1/4$, $1/8$, $1/16$, $1/32$, $1/64$ mol. %. In all cases the mixt. showed a lower conductivity than the value calcd. additively from the conductivity of unmixed solns. The diminution is greatest in $1/2$ mol. % H_3PO_4 solns. Pyrogallol has the most feeble action; it seems possible that 2 influences counteract each other: (1) A small increase in the H ions which will be strongest in the case of pyrogallol, (2) the formation of complex mols. with a conductivity lower than that of the components. The detn. of the abs. H ion concn. will answer the question. E. J. W.

The action of oxalyl chloride with some amides. TH. FIGER. Univ. Leyden. *Rec. trav. chim.* 34, 289-325 (1915).—Bornwater (*C. A.* 6, 2743) studied the action of (COCl) $_2$ on AcNH $_2$, ClCH $_2$ CONH $_2$ and BzNH $_2$, and found that in boiling C_6H_6 they gave carbonyl derivs., while substituted amines like AcNHEt and BzNHPh give oxalic derivs. Similarly treated NH $_2$ CO $_2$ Et gives CO(NHCO $_2$ Et) $_2$, while its Me deriv. gives (CONMeCO $_2$ Et) $_2$. NH $_2$ CONMe $_2$ gives the CO deriv., while (MeNH) $_2$ CO gives the cyclic oxalic deriv. (MeNHCO) $_2$ also gives the cyclic oxalic deriv. Moll v. Charante (*C. A.* 7, 1704) obtained the oxalyl deriv. with PhSO $_2$ NH $_2$, while Franchimont (*Kon. Acad. Wet.* 22, 285) obtained EtSO $_2$ NHMe with EtSO $_2$ NH $_2$. Me $_2$ CHCONH $_2$, however, decomps. partly in H $_2$ O into a nitrile in forming the oxalic deriv. But in working in Et $_2$ O soln. B. found that CO(NH $_2$) $_2$ + (COCl) $_2$ give parabamic acid, *i. e.*, a cyclic oxalic deriv. and another cyclic product, oxalyldiureide. Stollé (*C. A.* 8, 708) obtained diphenyloxamic chloride and tetraphenyloxamide from Ph $_2$ NH + (COCl) $_2$, depending on whether 1 or 2 mols. of Ph $_2$ NH were used. B. always used excess of the amine in order to obtain the oxalic derivs. and it seemed if only 1 mol. of amine was used with 1 mol. (COCl) $_2$, the chlorides like that found by S. would be obtained unless they underwent

intramol. rearrangement. Some examples of the latter are cited from Polpmer's data (C. A. 9, 1785). The expts. of B. were continued with PrNH_2 and $\text{PhCH}_2\text{CONH}_2$, partly to det. whether Ph in place of Me has a different effect. As substituted amides AcNHPh , PrNHPh and $\text{PhCH}_2\text{CONHPh}$ were used for the same reason. Moreover, PhNHCO_2Et , $\text{CO}(\text{NHPh})_2$ and $(\text{CONHPh})_2$ were used in place of the corresponding Me derivs. used by B. As homologs of PhNHCO_2Et F. has studied $\text{PhNHCH}_2\text{CO}_2\text{Et}$, and $\text{H}_2\text{NCHPh}_2\text{CO}_2\text{Me}$ (Meyeringh, *Rec. trav. chim.* 32, 152.) $\text{H}_2\text{NCONHPh}$, $(\text{CH}_2\text{NHCO}_2\text{Et})_2$ and $(\text{CH}_2\text{NHAc})_2$ were also used. Com. PrNH_2 was recrystd. in dry C_6H_6 instead of the usual CHCl_3 and was obtained as shining, nonhygroscopic leaves, m. $79-80^\circ$; 2 mols. boiled under a reflux condenser with 1 mol. $(\text{COCl})_2$ in dry C_6H_6 for 6 hrs. gave much HCl and sepd. a slightly brown compd. on cooling. This boiled with EtOH became white and was recrystd. from PhNO_2 as mica-like scales of *oxalyldi[propionamide]*, $(\text{CONHPr})_2$ (a), m. 216° (decompn.); yield 10%. 0.050 g. was boiled 0.30 hr. with 10% KOH under a reflux condenser, acidified with AcOH , treated with CaCl_2 soln. to ppt. CaC_2O_4 . (a) does not give the biuret reaction. EtCN was also formed which shows that $(\text{COCl})_2$ has a dehydrating action on PrNH_2 as was found by F. (l. c.) in the case of isobutyramide. The mother liquor on evapn. gave a yellow tar from which some (a) was sepd. in EtOH soln. and some unchanged PrNH_2 from petr. ether soln. 1 mol. $(\text{COCl})_2$ + 2 mol. $\text{PhCH}_2\text{CONH}_2$ (b) treated as with (a) sepd. a yellow powder which on crystn. from EtOH was found to be unchanged (b). The filtrate was evapd. and the residue recrystd. from boiling H_2O + EtOH , from which *carbonyldi[phenylacetamide]* (c), $\text{CO}(\text{NHCOCH}_2\text{Ph})_2$, sepd. as silvery plates, m. $114-6^\circ$, did not give $\text{H}_2\text{C}_2\text{O}_4$ on hydrolysis; it was noted that the introduction of 2 Ph groups in $\text{CO}(\text{NHAc})_2$ lowers the m. p. 2 mols. PhNHAc + 1 mol. $(\text{COCl})_2$ treated similarly seps. a little of a red compd.; the filtrate gives a brown viscous syrup on evapn., which crystd. from abs. EtOH , gave *oxalyldi[acetanilide]*, $(\text{CONPhAc})_2$ (d), colorless needles, m. $208-9^\circ$, gives $\text{H}_2\text{C}_2\text{O}_4$ on hydrolysis; a small amt. of a yellow product, m. $190-208^\circ$, was also formed. 2 mols. PhNH_2 + 1 mol. PrCl in dry Et_2O gave PhNHPr which was sepd. from PhNH_2Cl with H_2O . 2 mols. PhNHPr + 1 mol. $(\text{COCl})_2$ treated as in (a) sepd. a small amt. of a brown compd. and on evapn. gave a brown syrup which crystd. from EtOH gave impure *oxalyldi[propionanilide]* and unchanged PhNHPr . When 1 mol. PhNHPr + 1 mol. $(\text{COCl})_2$ were similarly treated *1-phenyl-3-methyl-2,4,5-triketotetrahydropyrrole* (e), MeHC.CO.CO.NPh.CO , or propionylisatin is formed.

Since the product gives $\text{H}_2\text{C}_2\text{O}_4$ on hydrolysis it is thought to be (e). The EtOH mother liquors give a little of an unidentified tetraketopyrrolidine deriv. 2 mols. $\text{PhCH}_2\text{CONH}_2$ + 1 mol. $(\text{COCl})_2$ similarly treated gave HCl and a yellow solid which recrystd. from AcOEt as yellow prisms, $\text{C}_{16}\text{H}_{11}\text{NO}_2$ (f), m. 235° , softens $215-20^\circ$, mol. wt. by Landsberger's b. p. method 260 (calcd. 265). Another compd., m. $114-6^\circ$, was sepd. which was thought to be unchanged $\text{PhCH}_2\text{CONH}_2$, m. 117° . (f) was either *1,3-diphenyl-2,4,5-triketotetrahydropyrrole* (*oxalphenylacetic anil*), PhHC.CO.CO.NPh.CO , or

phenylacetylisatin; the color indicated a deriv. of isatin; on hydrolysis it gave $\text{H}_2\text{C}_2\text{O}_4$, which is not given by isatin, and it did not give a blue color with concd. H_2SO_4 as isatin derivs. do, so that the former constitution is accepted. 1 mol. $\text{PhCH}_2\text{CONH}_2$ + 1 mol. $(\text{COCl})_2$ gave the same compd. Com. PhNHCO_2Et (g) was purified by distg., dissolving in abs. EtOH and pptg. with excess of H_2O by which (g) was sepd. as a turbid liquid, which was inoculated, crystd., powdered, and dried *in vacuo*; it m. $51-2^\circ$. 2 mols. (g) + 1 mol. $(\text{COCl})_2$ treated as for (f) gave HCl ; after agitating with H_2O unchanged (g) sepd. overnight. The mother liquor gave $\text{H}_2\text{C}_2\text{O}_4$. In a 2nd expt. H_2O was not added and the mixt. solidified in 4-5 days. Dissolved in petr. ether fine needles, m. $139-40^\circ$, sepd.; the H_2O soln. colors Congo paper blue; hydrolysis with KOH

gives $\text{H}_2\text{C}_2\text{O}_4$. In another expt. in which most of the C_6H_6 was 1st distd. off *N*-carbethoxyphenyloxamic acid (*h*), $\text{EtO}_2\text{CNPhCOCO}_2\text{H}$, was obtained, m. $140-1^\circ$. (*h*) is formed by the action of moisture on the $\text{EtO}_2\text{CNPhCOCOCl}$ first formed. 1 mol. $\text{CO}(\text{NHPh})_2$ + 1 mol. $(\text{COCl})_2$ give *diphenylparabanic acid*, PhN.CO.CO.NPh.CO ,

woolly needles, m. $206-7^\circ$. $(\text{CONHPh})_2$ does not react with $(\text{COCl})_2$; with KOH it hydrolyzes slowly. 1 mol. $(\text{COCl})_2$ + 4 mols. PhNHMe in dry Et_2O gave a powder of PhNHMe.HCl + $(\text{CONMePh})_2$ from which the latter was sepd. with H_2O ; it m. $111-1.5^\circ$; hydrolysis with KOH is much more difficult than for $(\text{CONHPh})_2$; the compd. described by Norton and Livermore (*Ber.* 20, 2273), b. $249-51^\circ$, is not $(\text{CONMePh})_2$. 2 mols. $\text{CO}(\text{NHPh})_2$ + 1 mol. $(\text{COCl})_2$ treated as for (*h*) gave *oxalyldi[phenylureide]*, $(\text{CONHCONHPh})_2$, silky needles, m. $238-40^\circ$, gives NH_3 + $\text{H}_2\text{C}_2\text{O}_4$ on hydrolysis with KOH, does not give the biuret test. The EtOH mother liquors also gave some *phenylparabanic acid*, PhN.CO.CO.NH.CO , shining scales, m. 208° . By treating

1 mol. $(\text{COCl})_2$ with 2 mols. $\text{H}_2\text{NCHPhCO}_2\text{Me}$, Meyeringh (*J. prakt. Chem.* 32, 20) obtained 2 isomeric compds., methyl oxalyldi[α -phenyl- α -aminoacetate], which F. has prepd. and subjected to the action of liquid NH_3 . 5 g. of the isomer (m. 168°) treated for 2 days in a pressure flask with liquid NH_3 at $8-12^\circ$ gave on evapg. the NH_3 a white product sol. in PhNO_2 from which *oxalyldi-[\alpha-phenyl- α -aminoacetamide]* (*i*), $(\text{CONHCHPhCONH})_2$, seps. as woolly, colorless crystals, m. 297° (browns 275°), insol. in H_2O but gives the biuret reaction. The isomer (m. $196-7^\circ$) gives similarly the isomer of (*i*), m. 282° (browns 245°), gives a biuret reaction; boiled with AcBr the compds. were recovered unchanged so that the compds. comparable to the peptides containing the oxalyl group could not be obtained in this way. 2 mols. $\text{PhNHCH}_2\text{CO}_2\text{Et}$ + 1 mol. $(\text{COCl})_2$ treated as for (*f*) sepd. colorless needles of *ethyl oxalyldi[phenylglycocolate]* + *benzene* (*j*), $(\text{CONPhCH}_2\text{CO}_2\text{Et})_2$, C_6H_6 , m. $105-6^\circ$; 4 g. (*j*) were distd. with excess of H_2O ; a thick, oily liquid free from the odor of C_6H_6 remained in the flask, and when crystd. from petr. ether gave (*j*) free from C_6H_6 as needle clusters, m. $87-8^\circ$. (*j*) treated with KOH for 0.5 hr. gives only a trace of $\text{H}_2\text{C}_2\text{O}_4$; prolonged heating gives more $\text{H}_2\text{C}_2\text{O}_4$. In attempting to prep. the diamide corresponding to (*j*) by treating with liquid NH_3 (*j*) was decompd. into phenylglycinamide and oxamide, and since the latter was recovered quant. the fact that it was an $\text{H}_2\text{C}_2\text{O}_4$ deriv. was proved. Since the rupture of the oxalyl group in (*j*) proceeds with difficulty it seemed possible that treating (*j*) carefully with dil. KOH would give oxalyldi[phenylglycocol] (*k*), $(\text{CONPhCH}_2\text{CO}_2\text{H})_2$. Heating 4 g. (*j*) in 25 cc. 10% KOH on the H_2O bath, cooling and adding excess of dil. H_2SO_4 sepd. (*k*) as an oil which crystd. in shining needles, m. $217-9^\circ$; titrations with NaOH (litmus indicator) showed it to be dibasic. 1 mol. ethylenedicarbamate in C_6H_6 soln. sepd. on cooling *2,3-diketo-1,4-N-dicarbomethoxypiperazine*, $\text{MeO}_2\text{CN.CO.CO.N}(\text{CO}_2\text{Me}).\text{CH}_2.\text{CH}_2$, brilliant crystals, m. 167° (softens 158°),

gives $\text{H}_2\text{C}_2\text{O}_4$ on hydrolysis with KOH; treated with liquid NH_3 at room temp. it gives a ppt. which recrystd. from boiling PhNO_2 gives oxamide and a compd. $\text{C}_7\text{H}_{12}\text{N}_4\text{O}_2$ which may be $\text{H}_2\text{NCONHCH}_2\text{CH}_2\text{NH}(\text{CO}_2\text{Me})\text{COCONH}_2$. 1 mol. diacetylene-diamine + 1 mol. $(\text{COCl})_2$ boiled with dry C_6H_6 gives a white insol. product which washed with boiling abs. EtOH and crystd. from AcOH gave *diacetyleneoxamide*, $\text{AcN.CO.CO.NAc.CH}_2\text{CH}_2$, as silvery leaves, m. $204-5^\circ$. F. in his summary discusses

the biuret reaction given by oxamide and certain oxalic derivs. According to Schiff (*Ann.* 229, 236) 2 CONH_2 groups or 1 CONH_2 and 1 CONHX group are necessary for this reaction, while with 2 CONHX groups it does not take place. F. has listed derivs. of oxamide prepared by himself, by M. (*l. c.*), by B. (*l. c.*) and G. (*l. c.*) and shows that

the biuret reaction occurs with *sym*-dialkyloxamides having the group (CONHalk), only when the amide function appears again in the alkyls as CONH₂ or as CONHX.

E. J. WITZEMANN.

Some derivatives of mesoxalic acid. D. J. VAN PROOYK. Univ. Leyden. *Rec. trav. chim.* 34, 326-49 (1915).—Since the discovery of easy methods of preparing esters of mesoxalic acid (*Ber.* 26, 3000; 27, 1782; *Am. Chem. J.* 35, 477; *Rec. trav. chim.* 29, 113) these and other derivs. of mesoxalic acid have been the object of many researches. Some have used the anhydrous esters of oxomalonic esters, others have used their hydrates, the esters of (HO)₂C(CO₂H)₂. v. P. has made some attempts with (HO)₂C(CO₂Et)₂ to prepare derivs. comparable to peptides containing the mesoxalyl groups but obtained no clear results. Equimol. amts. of (HO)₂C(CO₂Et)₂ (a) + urea were dissolved on the H₂O bath in sufficient abs. EtOH; on cooling there sepd. in a few days, fine, transparent needles, m. 132°, of what was thought to be the addition product, diethyl ureotartrate (b). Curtiss (*C. A.* 5, 1738) obtained the same compd. from CO(CO₂Et)₂ + urea. (a) was heated on the H₂O bath for some time with a 2nd mol. of urea in a little EtOH; the syrup obtained on evapg. the EtOH crystd. slowly as impure small needles, m. 98-100°, which are probably *monoethylureotartrate uride*, NH₂CONHCO(OH)C(NHCONH₂)CO₂Et; 1 OEt in (b) is replaced by urea. NH₂CONHPh, NH₂CONPh₂, CO(NHPh)₂, and NH₂CONMe₂ do not react with (a) in abs. EtOH nor in C₆H₆ or xylene. Attempts to make (a) react with NH₂CO₂H gave no result. Convinced that the H₂O in (a) does not hinder the reactions of the CO group sufficiently v. P. sought an addition product stable toward NH₃, alkalies and amines but from which the CO group or its hydrate could be easily obtained. The acetal could not be obtained by heating with EtOH 5 hrs. in a sealed tube at 100°. CBr₃(CO₂Me)₂ (Willstätter, *Ber.* 35, 1376) treated with a MeOH soln. of MeONa did not give the acetal. CBr₃(CO₂Et)₂ (b_m 152-5°) (96 g. in 30 cc. EtOH) was added drop by drop to 13.8 g. Na in 225 cc. alc., filtered and distd. and 0.75 l. Et₂O added to the residue, filtered, dried with Na₂SO₄, distilled and fractionated *in vacuo*, gave a liquid from which hexagonal colorless plates, m. 43°, of the acetal sepd.; av. yield, 13%. This compd. was used for the following expts.: (b) heated 15 min. on the H₂O bath with Ba(OH)₂ seps. *barium diethylmalonate*, C₇H₁₀O₄Ba.0.5H₂O, as a white, cryst. powder. A suspension of the Ba salt treated with the calcd. amt. of AgNO₃ soln. in the cold gave the dark insol. *silver salt*, C₇H₁₀O₄Ag₂, which was dissolved in NH₄OH and reprecip. as a white powder with HNO₃. The Ba salt agitated with the calcd. amt. of 10% H₂SO₄ gave on filtering and extg. with Et₂O an ext. which, crystd. from C₆H₆, gave small needles of *diethyloxymalonic acid*, m. 160° (decompn.). Attempts to prep. the chloride with POCl₃ and SOCl₂ failed. Treating (b) with aq. NH₃ or with liquid NH₃ gives *diethoxymalondiamide* (c), C₇H₁₄O₄N₂. (b) agitated with double the required amt. of 25% NH₃-H₂O for 24 hrs. dissolved completely and after some days deposited crystals of (c), m. 203-5°. (b) treated for 24 hrs. with liquid NH₃ in the sealed tube gave a residue on evapg. the NH₃ which gave crystals from EtOH identical with the preceding. The 1st method gives almost solely the diamide, the 2nd nearly 1/2 of *monoethyl diethoxymalonnate monoamide* (d), C₈H₁₇O₄N, shining needles, m. 94-5°; treated with NH₃ it gives (c). The monoamide is easily sol. in Et₂O and C₆H₆ in which (c) is insol. (c) boiled in C₆H₆ and AcCl for 6 hrs. did not react. Finally a large excess of AcCl was used and a little Ac₂O was added, HCl was evolved, the soln. was evapd. and *diethoxymalondiacetylamide* (e), C₁₁H₁₈O₆N₂, was crystd. from EtOH, fine needles, m. 125-6°. The same compd. was obtained by boiling (c) with Ac₂O for 3 hrs., or with AcBr and a little C₆H₆, while CH₃BrCOBr did not react. (d) remained intact when boiled 3 hrs. with Ac₂O + AcCl. (e) treated with liquid NH₃ in a sealed tube for 48 hrs. gave (c) + AcNH₂. Equimol. amts. of (c) boiled with (COCl)₂ in C₆H₆ for 6 hrs.

gave HCl and on evapg. the C_6H_5 a syrup which, dissolved in H_2O , sepd. *diethoxybarbituric acid* (f), $C_8H_{12}O_6N_2$, as fine, colorless needles, m. 165° . By dissolving (f) in concd. HNO_3 and evapg. nearly to dryness on the H_2O bath it gave on crystg. from boiling H_2O alloxan hydrate. (f) was also obtained by treating 24.8 g. (b) in 100 cc. abs. EtOH with 6.9 g. Na and 9 g. urea in 200 cc. abs. EtOH in the sealed tube at $100-10^\circ$ for 6 hrs. v. P. found that boiling trihydroxydihydromethyluracil (Osten, *Ann.* 343, 143) and trihydroxydihydrodimethyluracil (Henkel, *C. A.* 5, 876) with abs. EtOH gave the corresponding acetals, but the latter treated with alloxan or its hydrate did not give (f) as was hoped. (f) gives a *silver compound*, $C_8H_{10}O_4N_2Ag_2$, by substituting 2 H atoms bound to N. Anhydrous $MeNH_2$ acting on (b) in a sealed tube 2 days at room temp. seps. *dimalondimethylamide*, $C_8H_{12}O_4N_2$, as large crystals, m. 170° . Na was finely divided by agitation in boiling xylene, the xylene was removed and the Na treated with an Et_2O soln. of urethan which gave Na urethan + H, after which (b) was added and the mixt. heated $\frac{1}{2}$ hr. A solid sepd. which was filtered off and washed with Et_2O to remove unchanged (b). The residue was treated with weak H_2SO_4 until acid in reaction in which it dissolves. This extd. with Et_2O gave on evapg. and recrystn. *diethoxymalondicarboxyethylamide*, $C_{12}H_{22}O_8N_2$, white, irregular crystals, m. 114° ; treated with liquid NH_3 2 days at room temp. it gives (c), m. $204-5^\circ$, and NH_3CO_2Et , m. 51° . Attempts to obtain derivs. of (b) with derivs. of glycine and $m-NH_2C_6H_4CO_2H$ failed. A 2nd substance of which v. P. prepd. derivs. was $(PhO)_2C(CO_2Et)_2$ (g) (Conrad and Brückner, *Ber.* 24, 3004), yellow sirup, b_m 240° . Treated with liquid NH_3 for 3 days at room temp. a solid seps. which recrystd. from C_6H_6 as white flocks of *monoethyl diphenoxymalonate monoamide*, $C_{17}H_{17}O_4N$, m. $196-7^\circ$. (g) heated with liquid NH_3 2.5 hrs. at 72° in a sealed tube gave a brown residue on evapg. which dissolved in hot H_2O , sepd. *diphenoxymalondiamide*, $C_{18}H_{14}O_4N_2$, fine, white needles m. 269° , which was sepd. with some difficulty from the monoamide which is also formed in variable amts. Attempts to obtain the barbituric acid derivs. with $(COCl)_2$ failed. A mixt. of (g) with urea + $NaOEt$ in abs. EtOH heated in a sealed tube at 100° for 4 hrs. solidified gradually; this ppt., washed with a little EtOH, dissolved in H_2O , pptd. a white powder with HCl, which, dissolved in NaOH and repptd. with HCl, gave *sym-bis-[carboxydiphenoxymalonyl]urea*, $CO[NHCOC(OPh)_2CO_2H]_2$. The constitution was verified in part by the acid titration. Heated at its m. p. it loses 2 mols. CO_2 .

E. J. WITZEMANN.

Ephedrine and related compounds. AUGUST EDERHARD. Univ. Marburg. *Arch. Pharm.* 253, 62-91 (1915).—The object of the investigation was to ascertain the nature of certain secondary nitrogenous products formed along with Me_3N and N-free compds., when an aq. soln. of methylephedrine methohydroxide is repeatedly distd. (cf. *C. A.* 9, 2234). As the result of such treatment, Me_3N , methylephedrine and ephedrine are mainly formed while ephedrine phenylpropyleneoxide appears in less amt. During these expts. the following substances were characterized: *Methylephedrine methochloride*, $C_{10}H_{14}MeON.MeCl.H_2O$, right-angled plates from H_2O , m. 230° , $[\alpha]_D^{16} -30.54^\circ$; *methylephedrine chloroplatinate*, $(C_{10}H_{14}MeON.HCl)_2PtCl_4.2H_2O$, reddish yellow needles; m. (anhydrous) 181° , decomp. 184° . The behavior of methylephedrine methiodide toward Na-Hg was studied and the products of such action found in the main to be: Me_3N , methylephedrine, ephedrine and ephedrine phenylpropylene oxide. The *hydrochloride* of the last named substance forms compact right-angled plates sintering $146-8^\circ$ and m. $155-6^\circ$ (decompn.). The free base, $C_{10}H_{18}ON.C_6H_5O$, plates, soften 123° , m. 125° . The *aurate*, $C_{19}H_{22}NO_7.HCl.AuCl_3$, yellow needles, m. $144-5^\circ$. The *chloroplatinate*, $(C_{11}H_{12}NO_4.HCl)_2PtCl_4$, needles, m. $176.5-177^\circ$. The *methiodide* forms compact, yellowish crystals, m. 183° , the *methochloride*, needles, m. 203° . The methylation of ephedrine phenylpropylene oxide under varying conditions yielded

2 isomeric derivatives, one directly at the ordinary temp., $C_{11}H_{13}NO_2 \cdot MeI$, cubes, m. 183° (the corresponding *chloride*, needles, m. 203°), while the other from MeOH at 100° forms needles, m. 164° (the corresponding *chloride*, needles, m. $165-7^\circ$, and *chloroplatinate*, $(C_{11}H_{13}NO_2 \cdot MeCl)_2 \cdot PtCl_4$, orange needles, m. 188°). On treating ephedrine phenylpropylene oxide with BzCl *via* Schotten-Baumann, a *dibenzoyl derivative* resulted, $C_{19}H_{23}N(OBz)_2$, crystals, m. $141-2^\circ$. Expts. undertaken with a view to prepg. inactive ephedrine or pseudoephedrine by reducing $MeNHCHMeBz$ with Na-Hg lead to the formation of *methylaminoethylphenylcarbinol*, $C_6H_5CHOHCH(NHMe)Me$, felted needles, m. $114-5^\circ$ (*hydrochloride*, needles, m. $180-1^\circ$; *aurate*, m. 126° ; *chloroplatinate*, reddish warty crystals, m. $190-1^\circ$), having an odor very like pseudoephedrine (cf. Fournau, *J. pharm. chim.* 1904, 481; Buemming, *Diss. Marburg* 1909). W. O. E.

Organic fluorine compounds. I. J. RINKES. *Chem. Weekblad* 11, 360-4, 952-6 (1914); cf. *C. A.* 7, 769.—1-*Fluoro-2-chloro-4-nitrobenzene*: 60 g. of dry $p\text{-PhNO}_2$ and 6 g. anhydrous $FeCl_3$ at 130° were treated with dry Cl, and the resulting substance distd. with steam; it partly solidified in the receiver. The fraction which b. $227-32^\circ$ (45 g.) after crystn. from alc. solidified at 41° . 3-*Chloro-4-fluoroaniline* (a), from the NO_2 compd. with Sn and HCl, regular right-angled plates, m. 43.9° . *o-Fluoro-chlorobenzene*: 16 g. of (a) in 100 cc. of fuming HCl in ice and salt are diazotized with 10 g. $NaNO_2$, the resulting substance mixed with 60 g. $SnCl_4$ in 50 cc. fuming HCl, the hydrazine hydrochloride drained by suction, treated with NaOH and the base taken up in Et_2O . After evapn. of the Et_2O a colorless cryst. mass remained. This was dissolved in aq. AcOH, and dropped into 50 g. of $CuSO_4$ in 150 cc. boiling H_2O . The $o\text{-FC}_6H_4Cl$ distd. with a vehement gas evolution; it was washed with H_2O and then distd. under normal pressure. It is a colorless liquid, which smells like $PhCl$, b. 138.5° , m. -42.5° . *p-Fluoroanisole* (b): To obtain pure (b) R. started out from the F product of *p*-anisidine, which was hydrolyzed with $AlCl_3$ to $p\text{-FC}_6H_4OH$ which was esterified after purification by crystn. The *p-fluorophenol* thus obtained m. 46.5° . 11.2 g. of this were shaken for 1 hr. with 50 cc. of 10% NaOH and 120 cc. Me_2SO_4 . The (b) appears on the surface of the watery liquid; it b. 157° , m. -43.5° which is little higher than $p\text{-FC}_6H_4OMe$ prepared directly from *p*-anisidine (-45°). *p-Fluoronitrosobenzene* (c): 14.5 g. of finely powdered $(NH_4)_2S_2O_8$ was placed little by little in 20 g. of cold concd. H_2SO_4 , poured into 100 cc. iced H_2O , finely powdered Na_2CO_3 added until neutral and the ice-cold mixt. immediately added to 3.58 g. of $p\text{-FC}_6H_4NH_2$ (d) in 150 cc. H_2O . The (c), left in iced H_2O for some time, then drained by suction and purified by steam distn., m. 35.2° . 4,4'-*Disfluoroazobenzene* (e): The dark green soln. of 2.5 g. of $p\text{-O}_2NC_6H_4F$ in 7.5 cc. AcOH was mixed with 2.22 g. (d) in 5 cc. AcOH. After a short time the mixt. heated up to 45° and large crystals of (e) appeared. These, when drained by suction, dried on clay and recrystd. from alc., gave orange needles, m. 101.1° . R. found that only small quantities of $o\text{-FC}_6H_4OH$ could be obtained by diazotizing $o\text{-FC}_6H_4NH_2$, while better results might be had by diazotizing $o\text{-H}_2NC_6H_4OH$ (f) in presence of HF. 100 g. of (f) yielded 5 cc. $o\text{-FC}_6H_4OH$. (b), above, was made from *p*-anisidine (de Haen), 100 g. of which were placed little by little in 400 cc. of fuming HF, to which the calcd. amt. of $NaNO_2$ in a small quantity of H_2O , was added. The diazotized product is then dropped into 100 cc. of boiling HF. The distillate is partly neutralized, the (b) distd. with steam, dissolved in Et_2O , shaken with Na_2CO_3 , freed from Et_2O and distd. *in vacuo*. On a 2nd distn. under atm. pressure the main quantity b. 154.5° . *p-Fluorocyanobenzene* (g): 20 g. (d) obtained from the NO_2 compd. by reduction with very weak H_2SO_4 and Fe powder was added to a cold mixt. of 50 cc. strong HCl and 150 cc. HCl and diazotized with concd. $NaNO_2$ and the resulting compd. was added to a $Cu_2(CN)_2$ soln. (g) dists. over, and solidifies in the receiver to a yellow solid sepg. in colorless needles from naphtha. *p-Fluorophenylhy-*

drasine: To 20 g. (d) in 20 cc. cold HCl, a concd. soln. of 16 g. NaNO₂ was added and the resulting diazo compd. was mixed with 120 g. SnCl₂ in 100 cc. cold fuming HCl; the HCl salt which crystd. out was decompd. with NaOH, the base taken up in Et₂O, crystals in needles, m. 36.8°, and smells like PhNHNH₂. *p*-Fluorophenylhydroxylamine (h): 20 g. of *p*-FC₆H₄NO₂ in 120 cc. cold abs. alc. were satd. with dry NH₃, dry H₂S conducted into the soln. until a considerable deposit of NH₄SH had formed, allowed to stand 24 hrs. in an ice box, drained and the liquid mixed with 400 cc. dry Et₂O, which gave another cryst. ppt. The red alc.-Et₂O soln. of (h) was repeatedly shaken with small quantities of H₂O to remove adhering (NH₄)₂SO₄, the Et₂O removed from the slightly yellow soln. by distn., and the residue dissolved in boiling C₆H₆, from which the FC₆H₄NHOH sep'd. on cooling in irregular needles, m. 90°. 4.65 g. finely powdered (h) in 16 cc. ice-cold concd. H₂SO₄ and 270 cc. H₂O were treated with 4.6 g. of K₂Cr₂O₇ in 200 cc. cold H₂O, and steam blown into the oxidizing liquid; the resulting (c) dists. over in a few min. The crystals, when pure, are snow-white and after drying on a porous plate, m. 35.2°.

J. T. FLOHIL.

Action of nitric acid on the three isomeric fluorotoluenes. J. H. SLOTHOUWER. *Chem. Weekblad* 11, 956-8 (1914).—6-8 parts of HNO₃ (d. 1.48) were dropped, while stirring, into FC₆H₄Me at 0°. A glass plate covered with beeswax in which some figures were scratched was held over the liquid. The etching of the glass proved that F leaves the ring during the nitration. The yellow cryst. substance resulting from the nitration, dissolved in NaOH, pptd. by HCl, taken up in Et₂O, freed from Et₂O and twice recrystd. from H₂O, m. 32°, and proved to be identical with 4,3-HO(O₂N)C₆H₂Me (a). 5 g. of (a) further nitrated with HNO₃ (d. 1.52) at 0° gave rise to 2 g. dinitrocresol. During the nitration, lower acids occur after F has left the ring. Besides (a), which is the main product, very small amts. of 2 nitrofluorotoluenes, a solid, m. 27°, b_m 138-9°, and a liquid, b_m 134.5°.

J. T. FLOHIL.

The structure of quinoline red. L. P. KRANTZ. *Chem. Weekblad* 11, 364-7

(1914).—K. announces that the structure of quinoline red,

as suggested by himself is inferior to that offered by Homann (*Diss. Jena* 1913)

whose formula

better explains certain properties of

J. T. FLOHIL.

Friedel-Crafts synthesis of sulfones. S. C. J. OLIVIER. *Chem. Weekblad* 11, 372-7(1914); cf. *C. A.* 9, 442.—O. investigated the action of AlCl_3 in Friedel and Crafts' synthesis of sulfones and draws the following conclusions: $\text{C}_6\text{H}_4\text{BrSO}_2\text{Cl} \cdot \text{AlCl}_3$ is the reacting compd. in the formation of $p\text{-BrC}_6\text{H}_4\text{SO}_2\text{Ph}$ in C_6H_6 and gives rise to $\text{C}_6\text{H}_4\text{BrSO}_2\text{Ph} \cdot \text{AlCl}_3$. Free sulfonyl chloride (present when AlCl_3 is not in excess) is not able to withdraw AlCl_3 from $\text{C}_6\text{H}_4\text{BrSO}_2\text{Ph} \cdot \text{AlCl}_3$. Neither of these addition compds. is dissociated in C_6H_6 ; the catalytic action is caused by the combined AlCl_3 , partly by that which is combined with sulfonyl chloride, partly by that which is combined with sulfone. The catalytic action is proportional to the total combined AlCl_3 . The small quantity of free AlCl_3 present in the soln. when an excess of this substance has been employed acts considerably stronger as a catalyst than the combined AlCl_3 . The formation of addition compds. is considered to be accidental. The velocity of reaction with C_6H_6 as a solvent may be represented by the formula $dx/dt = [k(\text{C}_6\text{H}_4\text{BrSO}_2\text{Cl} \cdot \text{AlCl}_3) + k_1(\text{sulfone}, \text{AlCl}_3) + k_2(\text{AlCl}_3)_n](\text{C}_6\text{H}_4\text{BrSO}_2\text{Cl} \cdot \text{AlCl}_3)$, in which $k_2 = k_1$, $k_2 > k_1$, $n = \text{unknown}$, perhaps 1. J. T. FLOHIL.

o-Nitrosophenol. II. OSKAR BAUDISCH AND S. ROTHSCHILD. Univ. Zurich. *Ber.* 48, 1660-5(1915); cf. *C. A.* 6, 2600.—*o*- $\text{ONC}_6\text{H}_4\text{OH}$ (a) is obtained in good yield when $\text{MeC}_6\text{H}_4\text{SO}_3\text{C}_6\text{H}_4\text{NO}$ is boiled a long time with lime over a free flame, cooled, filtered, evapd., to dryness on the H_2O , dissolved in a little H_2O bath, covered with petr. ether and shaken vigorously with HPO_3 ; the emerald-green petr. ether soln. is stable for months and can be used for the detection of traces of Cu; as the Cu salt of (a) is insol. in petr. ether, in testing for Cu Et_2O is added; this easily dissolves the Cu salt with deep red color. Another method of obtaining (a) is as follows: To 5 g. *o*- $\text{MeOC}_6\text{H}_4\text{NO}_2$ and 8 g. AmNO_2 shaken to an emulsion with 50 cc. concd. NH_4OH and 20 cc. of 96% alc. is added 7.5 g. Zn dust in small portions, the temp. rising to the b. p.; after 0.5 hr. the hot soln. is filtered, extd. twice with Et_2O to remove unchanged $\text{MeOC}_6\text{H}_4\text{NO}_2$, treated with excess of $\text{Cu}(\text{OAc})_2$ and acidified with AcOH ; copper *o*-methoxynitrosophenylhydroxylamine, $[\text{MeOC}_6\text{H}_4\text{N}(\text{NO})\text{O}]_2\text{Cu}$, seps. in Ag-gray crystals and, when washed with H_2O and boiled with xylene, gives the Cu salt of (a) (although in very poor yield). Manganese-*o*-nitrosophenylhydroxylamine *p*-toluenesulfonate, $\text{C}_{10}\text{H}_9\text{O}_3\text{N}_2\text{S}_2\text{Mn}$, obtained from 2 g. of the NH_4 salt in 50 cc. H_2O and 2-3 drops NH_4OH treated at 0° with $\text{Mn}(\text{NO}_3)_2$ and cautiously acidified with cold HPO_3 , white-gray ppt. from C_6H_6 -ligroin. Manganese-*o*-hydroxynitrosophenylhydroxylamine (b), from 10 g. of the NH_4 salt of the nitroso sulfonate boiled 45 min. over a free flame with 1.7 g. NaOH until all the NH_3 is expelled, cooled to 0° , treated with cold $\text{Mn}(\text{NO}_3)_2$, cautiously acidified with HPO_3 , quickly filtered, dissolved directly on the filter with AcOEt and pptd. with low-boiling ligroin, very unstable brown crystals continuously losing N_2O_2 and going over into manganese-*o*-nitrosophenol; the latter is obtained by heating 5 g. (b) in 200 cc. AcOEt 3-4 hrs. on the H_2O bath or still better by shaking with AcOEt the Na salt corresponding to (b) in H_2O in the presence of $\text{Mn}(\text{NO}_3)_2$ and HPO_3 at 0° , washing with NaCl , drying with Na_2SO_4 , concg. to a small vol. and pptg. with ligroin; it forms red-brown, almost black crystals with greenish surface luster, sol. in almost all org. solvents except ligroin with deep red color, best crystd. by boiling 1 g. 3 hrs. with 500 cc. AcOEt-EtOH (2:1) and filtering. In the same way from the Na salt, $\text{Al}(\text{NO}_3)_3$ and HPO_3 is obtained aluminium-*o*-nitrosophenol, almost black crystals. CHAS. A. ROUITLER.

m-Nitrosoanisole. OSKAR BAUDISCH AND ROSE FÜRST. Univ. Zurich. *Ber.* 48, 1665-70(1915); cf. preceding abstr.—Ammonium *m*-methoxynitrosophenylhydroxylamine, $\text{MeOC}_6\text{H}_4\text{N}(\text{NO})\text{ONH}_4$ (a) is obtained from 10 g. *m*- $\text{MeOC}_6\text{H}_4\text{NO}_2$ in 200 cc. of cold 96% alc. satd. with NH_3 gas, then treated with H_2S at room temp. until there is a copious deposition of $(\text{NH}_4)_2\text{S}$, allowed to stand 24 hrs. in the ice chest, filtered, freed of dissolved $(\text{NH}_4)_2\text{S}$ and polysulfides by pptn. with Et_2O and filtration, treated with

NaCl soln. until the Et_2O layer is clear and the latter washed with concd. NaCl until the wash waters give no test for H_2S ; the Et_2O soln., which gives all the reactions of hydroxylamines but from which the $\text{MeOC}_6\text{H}_4\text{NHOH}$ could not be isolated, is dried with Na_2SO_4 , treated at 0° with dry NH_3 and then with fresh AmNO_3 , whereupon it solidifies to a thick mush of (a), very stable chalky powder, m. 135° after pptn. from alc. with Et_2O (yield, about 50%); it easily dissolves, without color, in H_2O at room temp. and when the soln. (best in small quantities in test tubes) is treated at -10° with $\text{Br}\cdot\text{H}_2\text{O}$ at 0° as long as the Br color instantly disappears, *m-methoxynitrosobenzene* is formed as a pure white, granular ppt., sol. in all org. solvents with green color, turns green at 40° , m. 48° to emerald-green drops and becomes brown at 80° ; the green melt in the m. p. tubes, allowed to stand in the air, decomps. quickly, becoming completely brown in 2 hrs. The alc. soln. gives at once at room temp. a red compd. with 2,4-(O_2N) $_2\text{C}_6\text{H}_3\text{Me}$ and KOH; with quinaldine ethiodide alone, there is no reaction but on addition of a trace of alkali a dark violet-red color appears. When $\text{Cl}\cdot\text{H}_2\text{O}$ is used instead of Br a bright green product is obtained which m. 42° to deep green drops and again at 75° (with violent foaming) to a brown liquid; after a few days it becomes dirty greenish yellow, no longer dissolves with green but with yellow color in org. solvents, and no longer m. at 42° but only at 75° (foaming); on standing in closed vessels it decomps. completely to a dark brown, moist tar. Freshly pptd., it gives a deep red, Et_2O -sol. Fe salt and therefore probably contains considerable free *m*- $\text{MeOC}_6\text{H}_4\text{N}(\text{NO})\text{OH}$. The freshly pptd. product recrystd. several times from hot ligroin (b. $70\text{--}80^\circ$) gives the yellowish white needles, m. 77° , of the free *m-methoxynitrosophenylhydroxylamine*, which can be obtained from (a) and HPO_3 and is remarkably stable, weathering only after months on clay but more quickly in closed vessels. Aq. (a) and $\text{Cu}(\text{OAc})_2$ give a dark blue voluminous ppt. of the salt $[\text{MeOC}_6\text{H}_4\text{N}(\text{NO})\text{O}]_2\text{Cu}$, forming a light gray powder sol. in CHCl_3 with dark blue color. *Ferric salt*, yellow-brown, sol. in org. solvents with yellow to red color.

CHAS. A. ROULLER.

Some aminoazimido bases and their azo dye derivatives. O. KYM AND M. RINGER. Univ. Zurich. *Ber.* 48, 1671-85 (1915); cf. *C. A.* 6, 356.—As was expected, the azo dye derivs. of azimidobenzene compds., $\text{C}_6\text{H}_4\text{NH.N:N}$, having a 5-membered ring similar

to that of benzimidazole, benzothiazole or benzoxazole compds., $\text{C}_6\text{H}_4\text{R.CH:N}$ ($\text{R} = \text{NH}$,

S or O), are substantive dyes capable of dyeing cotton directly without mordants, although they stand behind the imidazole compds. in this respect. *5-Nitro-2,3-toluylenediamine* (a), in 50% yield from 10 g. 2,3,5- $\text{H}_2\text{N}(\text{O}_2\text{N})_2\text{C}_6\text{H}_3\text{Me}$ in 33 cc. boiling alc. treated with 18 g. crystd. Na_2S in 30 cc. H_2O , then dild. with 4 vols. cold H_2O , the red cryst. ppt. dissolved in cold dil. HCl, filtered, pptd. with NH_3 and crystd. from dil. alc., felted orange-red needles, m. 185° , easily sol. in dil. HCl; *diacetyl derivative*, obtained with Ac_2O on the H_2O bath, pale yellow needles from dil. alc., m. 234° , insol. in cold dil. HCl, but dissolves on warming; NH_3 now, however, ppts. the anhydro compd., *5-nitro-1- α -dimethylbensimidazole*, $\text{Me}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{NH.CMe:N}$, obtained

directly by boiling (a) 4 hrs. with AcOH, dilg. with much cold H_2O , filtering, making just alk. with NH_3 and crystg. from H_2O ; it m. 186° , and dissolves easily in dil. HCl and also, with pure yellow color, in cold dil. NaOH. *5-Nitro-1-methylbensimidazole*, from (a) boiled a long time with HCO_2H , needles from H_2O , m. $199\text{--}200^\circ$, sol. in dil. HCl and, with yellow color, in dil. NaOH. *5-Nitro-1-methyl- α -hydroxybensimidazole*, from 1 g. (a) and 2.5 g. urea heated 1 hr. at $160\text{--}70^\circ$ until a solid cryst. mass is formed (evolution of NH_3), dissolved in warm dil. NaOH, filtered, pptd. with dil. HCl and crystd. from much hot H_2O , hair-like needles, m. $329\text{--}30^\circ$, sol. in cold dil. NaOH with

intense yellow color, excess of concd. NaOH pptg. a cryst. brick-red Na salt. *5-Nitro-1-methyl-2,3-asimidobenzene*, quant. obtained from (a) in cold dil. HCl and the calcd. amt. of NaNO_2 , yellow needles from dil. alc., m. $252-3^\circ$, sol. in hot alc., Me_2CO or AcOH with yellowish color, in concd. HCl and, with intense yellow color, in dil. NaOH, reduced by SnCl_2 , Sn and concd. HCl to the *amino compound*, brownish needles losing H_2O of crystn. at $80-5^\circ$ and m. $161-2^\circ$, easily sol. in cold dil. alkalies; *acetyl derivative*, obtained with NaOAc and boiling Ac_2O , needles from dil. alc., m. 283° , insol. in dil. HCl but easily sol. in dil. NaOH, gives with ice-cold NaOH and Ac_2O the *diacetyl derivative*, Ag-white needles from Me_2CO , m. $239-40^\circ$, which, boiled 1 hr. with H_2O , loses AcOH and regenerates the mono-Ac compd. $2,4,5\text{-H}_3\text{N}(\text{AcNH})_2\text{C}_6\text{H}_2\text{Me}$, from 2 g. of the NO_2 compd. added in small portions to 4 g. Fe filings in 100 cc. of warm 5% AcOH, warmed not more than 0.5 hr. (otherwise the imidazole is formed in considerable amt.), dild. with 60 cc. hot H_2O , filtered hot, freed from Fe with solid soda, filtered hot, concd. and crystd. from H_2O , m. $252-3^\circ$ (cf. Maron, C. A. 6, 362); with somewhat more than the calcd. amt. of NaNO_2 in cold dil. HCl, it at once gives *1-methyl-2-acet-amino-4,5-acetylasimidobenzene*, $\text{Me}(\text{AcNH})\text{C}_6\text{H}_2\text{N}(\text{Ac})\text{N}:\text{N}$, needles from Me_2CO , m.

220° , easily sol. in dil. NaOH and concd. HCl, loses both Ac groups when boiled 5 min. with dil. HCl; boiled 1 hr. with 50 parts H_2O it gives *1-methyl-2-acetamino-4,5-asimidobenzene*, needles, m. 235° , also obtained by recrystg. the di-Ac compd. twice from PhNO_2 or evapg. its $\text{C}_6\text{H}_5\text{N}$ soln. on the H_2O bath and converted back into the di-Ac compd. with Ac_2O and cold NaOH; it is sol. in dil. alkalies and in concd. HCl; 1 g. heated on the H_2O bath with 15 cc. H_2O , 5 cc. alc. and 5 cc. concd. HCl gives *1-methyl-2-amino-4,5-asimidobenzene*, needles from H_2O , m. 173° (on slow cooling of the aq. soln. it seps. in red-brown prisms with H_2O of crystn. in which it m. $80-3^\circ$), sol. in dil. NaOH, gives with concd. HCl a difficultly sol. salt at once dissolving on addition of H_2O . *o-Amino-p,m'-dinitrodiphenylamine* (b), obtained in 60% yield from 5 g. $\text{O}_2\text{NC}_6\text{H}_4\text{NHC}_6\text{H}_3(\text{NO}_2)_2$ in 30 cc. each of warm Me_2CO and alc. treated with 10 g. crystd. Na_2S in 20 cc. hot H_2O , heated 10 min. on the H_2O bath, cooled, dild. with 4 vols. of H_2O , the brown voluminous ppt. extd. with boiling Me_2CO and a few drops of NH_4OH until the ext. gives no ppt. with H_2O , the H_2O ppt. dissolved in boiling dil. HCl (1:4), pptd. with NH_4OH , allowed to stand some hrs. in the cold and crystd. from dil. alc., red needles, m. $207-8^\circ$, easily sol. in very dil. HCl, sol. in boiling NaOH with red color and loss of NH_3 ; *acetyl derivative*, golden yellow needles from Me_2CO , m. 205° . *N-m-Nitrophenyl- α -methyl-p-nitrobenzimidazole*, from (b) covered with hot Ac_2O and 1-2 drops concd. H_2SO_4 , whereupon the (b) dissolves with energetic reaction, then dild. with H_2O , brought to a boil, filtered and cooled, pptd. from dil. HCl with NH_4OH and crystd. from alc., Ag-white needles, m. $226-7^\circ$, easily sol. in cold dil. HCl, insol. in cold or hot alkalies, also obtained by heating the above Ac deriv. a short time at its m. p. or boiling it in dil. HCl. *N-m-Nitrophenyl-p-nitroasimidobenzene*, from (b) and NaNO_2 in cold dil. HCl, yellow-brown needles from $\text{C}_6\text{H}_5\text{N}\cdot\text{H}_2\text{O}$, m. 181° , insol. in HCl or NaOH. *N-m-Aminophenyl-p-aminoasimidobenzene*, from 1 g. of the di- NO_2 compd., 2.5 g. SnCl_2 and a little Sn cautiously warmed on the H_2O bath with 5 cc. concd. HCl until a clear soln. results, dild. with H_2O , filtered, supersatd. with cold NaOH, repeatedly pptd. from cold dil. HCl with NaOH, dried on clay, dissolved in hot Me_2CO , treated with an equal vol. of hot H_2O and slowly freed from Me_2CO on the H_2O bath, brownish needles, m. $214-5^\circ$, easily sol. in dil. HCl; when covered with Ac_2O it dissolves with evolution of heat and at once deposits the *diacetyl derivative*, sepg. from alc.- H_2O in gelatinous flocks which dry on clay to gleaming scales, m. $248-9^\circ$. For details concerning the prepn. of the azo dyes and the dyeing expts. cf. R.'s dissertation (Zurich, 1915).

CHAS. A. ROUILLER.

Fat acid esters of ethylene glycol. R. F. RUTMAN AND J. R. ROEBUCK. *Trans. Roy. Soc. Canada* [3] 9, June, 1915, 11 pp.—Glycol distearate (Wurtz, *Ann. chim. phys.* [3] 55, 436(1859), prepd. by nearly satg. the acid in alc. with NH_3 , treating with an equiv. amt. of alc. AgNO_3 , distg. off the excess of NH_3 and a little of the alc., cooling allowing to stand, filtering, washing and drying the resulting cryst. Ag salt, adding it in small portions to an excess of $(\text{CH}_2\text{Br})_2$ at about 131° , heating 2–4 hrs., distg. off the excess of $(\text{CH}_2\text{Br})_2$, extg. with boiling Et_2O , filtering warm, evapg. and crystg. from nearly abs. alc., pearly plates (sometimes needles from Et_2O), m. 75° , n_{D}^{25} 1.4385, d_{40}^{25} 0.8581; sol. in 100 g. abs. alc., 0.010 and 0.112 g. at 0° and 40° , resp. The intermediate product, $\text{BrCH}_2\text{CH}_2\text{O}_2\text{CC}_{17}\text{H}_{35}$, which must be formed, could not be isolated. Both the mono- and di-esters are more conveniently prepd. by heating 100 g. acid with 1.5 mols. glycol at $180\text{--}90^\circ$ in a flask provided with a Pt stirrer for 4–7 hrs., washing the resulting mixt. 2–3 times with hot H_2O , allowing to cool, removing the cake of fat, detg. the excess of acid by titration and sepg. it by fusing on the H_2O bath with the calcd. amt. of $\text{Ca}(\text{OH})_2$, extg. with Et_2O , filtering hot, evapg. and crystg. repeatedly from alc., there always remains 10–5% of almost non-cryst., very sol. substance. The yield of di-ester is always many times greater than that of mono-ester. *Mono-stearate*, m. 58.5° , n_{D}^{25} 1.4310, d_{40}^{25} 0.8780; solubility in 100 g. alc., 0.64 and 10.61 g. at 0° and 29° . *Dipalmitate*, m. 68.7° , n_{D}^{25} 1.4378, d_{40}^{25} 0.8594; solubility in 100 g. alc., 0.018 and 0.31 g. at 0° and 38° . *Monopalmitate*, m. 51.5° , n_{D}^{25} 1.4411, d_{40}^{25} 0.8786; solubility in 100 g. alc., 1.62 and 24.08 g. at 0° and 25° . *Dimargarate*, m. 65.5° , solidifies 64.7° , n_{D}^{25} 1.4392, d_{40}^{25} 0.8605; solubility in 100 g. alc. 0.024 and 0.101 g. at 0° and 25° . *Monomargarate*, thin plates from dil. alc., m. 50.2° , n_{D}^{25} 1.4440; 1.72 g. dissolves in 100 g. alc. at 0° . The *oleates* were obtained only in pasty condition at low temps. and rapidly hydrolyzed and oxidized. *Glycol chloride stearate* (a), $\text{ClCH}_2\text{CH}_2\text{O}_2\text{CC}_{17}\text{H}_{35}$, from equiv. amts. of $\text{ClCH}_2\text{CH}_2\text{OH}$ and $\text{C}_{17}\text{H}_{35}\text{CO}_2\text{Ag}$ heated 18 hrs. at $105\text{--}15^\circ$, extd. with hot Et_2O , filtered hot, evapg. and crystd. repeatedly from alc., m. 48.5° , d_{40}^{25} 0.9049, n_{D}^{25} 1.4433; solubility in 100 g. alc., 0.20 and 3.62 g. at 0° and 29° . *Chloride palmitate*, m. 41.5° , n_{D}^{25} 1.445, d_{40}^{25} 0.9097; solubility in 100 g. alc., 0.48 and 15.31 g. at 0° and 29° . *Glycol stearate palmitate*, from (a) and $\text{AgO}_2\text{CC}_{15}\text{H}_{31}$ heated 3–4 hrs. at 140° , or $\text{KO}_2\text{CC}_{15}\text{H}_{31}$ heated much longer, m. 65° , d_{40}^{25} 0.8584, n_{D}^{25} 1.4391, solubility in 100 g. alc., 0.011 and 0.213 g. at 0° and 39° . C. A. R.

Catalytic reduction of unsaturated compounds. X. Reduction of aromatic alcohols, aldehydes and ketones. A. SKITA. *Ber.* 48, 1685–98(1915); cf. C. A. 9, 3249.—While the expts. with BzH and Ph_3CO previously reported did not give much hope of the possibility of reducing aromatic aldehydes and ketones by the catalytic method to the corresponding hydro aldehydes and ketones, the products in these cases having been PhMe and hexahydrotoluene on the one hand and CH_3Ph and $(\text{C}_6\text{H}_{11})_2\text{CH}_2$ on the other, the results were entirely different with PhCH:CHCHO (a); 10 g. (a) in 100 cc. alc., 10 cc. of 1% PdCl_2 , 20 cc. of 2% gum arabic and 30 cc. H_2O absorbs 1 mol. H_2 in 1 hr., when the Pd flocculates out and absorption ceases; the soln. is filtered, the alc. distd. off *in vacuo* and the residue treated with H_2O , the resulting yellow oil extd. with Et_2O , dried with ignited potash and fractionated, giving almost exclusively $\text{PhCH}_2\text{CH}_2\text{CHO}$, together with 0.8 g. $\text{PhCH:CHCH}_2\text{OH}$. When 6 g. (a) in 45 cc. AcOH , 10 cc. of 5% H_2PtCl_6 , 25 cc. of 2% gum arabic and 10 cc. of inoculation soln. is reduced, the 1st mol. of H_2 is absorbed in 0.5 hr. under 1 atm. excess pressure and the 2nd only in 6 hrs., when there is practically no more absorption, even under 3 atm. excess pressure; the product obtained by extg. the neutralized reaction mixt. with Et_2O yields on fractionation 0.3 g. PhPr , b. 157° , while the main fraction consists of $\text{PhCH}_2\text{CH}_2\text{CH}_2\text{OH}$, b. 235° . When 5 g. (a) in 50 cc. AcOH , 10 cc. of 10% H_2PtCl_6 , 30 cc. of 2% gum arabic and 16 cc. of inoculation soln. (0.003 cc. Pt per cc.) is reduced

under 3 atm. excess pressure, 5 mols. H_2 are absorbed in 5 hrs., the 1st in 0.5 hr., the 2nd in 1.5 hrs. and the last 3 in 3 hrs., when absorption practically stops; the soln. is made alk., distd. with steam and the oil fractionated; besides small amts. of PhPr, b. 157° , $C_6H_{11}Pr$, b. 147° , and $PhCH_2CH_2CH_2OH$, b. $230-40^\circ$, the chief product is *hexahydrophenylpropyl alcohol*, b. $222-4^\circ$, $d_{20} 0.9358$, has a penetrating odor; *acetate*, $b_{18} 120-1^\circ$, $d_{20} 0.9398$; with $Na_2Cr_2O_7-H_2SO_4$ in hot dil. AcOH the alc. yields the *aldehyde*, $b_{18} 87-8^\circ$ (yield, 3 g. from 8 g. alc.), isolated through the *semicarbasone*, crystals from C_6H_6 -petr. ether, m. 128° . The fact that after the quick absorption of the 1st mol. of H_2 (formation of $PhCH_2CH_2CHO$), the 2nd mol. (formation of $PhCH_2CH_2CH_2OH$) is absorbed much more slowly than the last 3 (hydrogenation of the nucleus) is explained by the assumption that between the Pt metal and Pt compds. on the one hand and the aromatic double bonds on the other are formed double compds. which act as carriers of the H. In the reduction of $PhCH_2CHO$, besides the chief product *hexahydrophenylethyl alcohol* (b), liquid of a rose-like odor, b. $206-9^\circ$ (*acetate*, $b_{18} 104^\circ$), considerable more of the hydrocarbons, PhEt and $C_6H_{11}Et$, are formed than in the case of (a). With $K_2Cr_2O_7-H_2SO_4$ in hot dil. AcOH (b) gives 34% of the *aldehyde*, $b_{18} 79-80^\circ$, isolated through the *semicarbasone*, m. 153° after crystn. from dil. alc. (b) is obtained more quickly and in better yield when the $PhCH_2CHO$ is reduced in the form of the acetate of its enol. compd., *vis.*, $PhCH:CHOAc$, and it is well to isolate the intermediate compd., $PhCH_2CH_2OAc$; 3.9 g. of this, $b_{18} 118-20^\circ$, in 30 cc. AcOH, 10 cc. of 5% H_2PtCl_6 , 10 cc. of colloidal inoculation soln. and 5 cc. of 2% gum arabic absorbs 3 mols. H_2 under 3 atm. excess pressure in 2 hrs. Acylation, however, is not a general protection of the aldehyde group against reduction to the hydrocarbon; $PhCH_2OBz$, $PhCH_2OAc$, $PhCH(OAc)_2$ give PhMe; even $PhCH_2OEt$ gives chiefly PhMe. When, however, 15 g. $PhCH_2NHPh$, from BzH and $PhNH_2$ and subsequent reduction of the $PhCH:NPh$ with Na and alc., in 150 cc. AcOH, 60 cc. of 10% H_2PtCl_6 , 22 cc. of 10% gum arabic and 15 cc. of inoculation soln. is reduced under 3 atm. excess pressure, 6 mols. H_2 are absorbed in 3 hrs.; the filtered soln. is made alk. with concd. NaOH, extrd. with Et_2O , dried and fractionated, yielding, besides 3.5 g. of $C_6H_{11}NH_2$ and $C_6H_{11}Me$, 18 g. of *dodecahydrobensylaniline* (c), b. 270° , volatile with steam, forms with $NaNO_2-HCl$ a nitrosamine, which gives the Liebermann reaction with $PhOH-H_2SO_4$ and regenerates (c) with Zn and acids; *hydrochloride*, crystals from Et_2O -alc., m. 305° . Slowly treated in cold Me_2CO with $KMnO_4$ in aq. Me_2CO (c) gives the *bensalaniline*, which, on treatment with concd. HCl, yields 42% of $C_6H_{11}CHO$, b. $160-5^\circ$. Similarly, 5 g. $Ph_3CHNHPh$, $b_{18} 224-5^\circ$ (from the HCl salt, m. 202.5°), in 113 cc. AcOH, 35 cc. of 10% H_2PtCl_6 , 17 cc. of inoculation soln., 10 cc. of 2% gum arabic, 75 cc. of H_2O and 100 cc. of AcOH at 50° under 1 atm. excess pressure absorbs 3 mols. H_2 in 5 min. and another 3 in 20 min. (with colloidal Pt instead of H_2PtCl_6 , the times required are 25 and 60 min., resp., under 3 atm. excess pressure); there are obtained 0.3 g. $C_6H_{11}NH_2$, b. 134° ; 1.3 g. *dodecahydrodiphenylmethane*, b. $247-8^\circ$; and chiefly *dodecahydro[phenyliminodiphenylmethane]*, $Ph(C_6H_{11})CHNHC_6H_{11}$, $b_{18} 189^\circ$ (*hydrochloride*, needles from alc.- Et_2O , m. $276-7^\circ$), which with $Na_2Cr_2O_7$ in boiling 50% H_2SO_4 gives hexahydrobenzophenone; *semicarbasone*, crystals from C_6H_6 -petr. ether, m. 175° . That the reduction proceeds more rapidly with H_2PtCl_6 than with colloidal Pt is further confirmation of the correctness of the assumption of double compds. acting as H carriers.

CHAS. A. ROULLER.

sym-m-Xylenol. K. v. AUWERS AND E. BORSCHKE. Marburg. *Ber.* 48, 1698-716(1915); cf. C. A. 9, 1057.—As previously reported, 3,5- $Me_2C_6H_3OMe$ (a), when treated with CCl_4 and $AlCl_3$, gives, instead of the expected *p*-HO ketone, the two *o*-derivs., 2,3,5- $AcMe_3C_6H_2OH$ (b), and 2,6,3,5- $Ac_2Me_2C_6H_2OH$ (c), the constitution of which is indicated by the fact that both compds. are volatile with steam and is proved

by the work described below. The Me ether of (b), m. 48–9°, b_{14} 135°, is obtained in 80–90% yield from equimol. amts. of (a) and AcCl in 3 vols. cold CS_2 treated with an amt. of AlCl_3 equal to the wt. of (a) with thorough cooling and frequent shaking and allowing to stand 1–2 days at room temp. *Oxime*, from the ketone, 2 mols. $\text{NH}_4\text{OH} \cdot \text{HCl}$ and 6 mols. NaOH allowed to stand 2 days in aq. alc. soln., prisms from C_6H_6 or PhMe , m. 135°; *semicarbazone*, from the ketone, $\text{H}_2\text{NCONHNH}_2 \cdot \text{HCl}$ and KOAc heated 2 days at 50°; microcrystals, m. 185°. If the oxime in excess of Ac_2O is allowed to stand some hrs. and then evapd. *in vacuo* over NaOH , it leaves a colorless oil, doubtless the *oxime acetate*, which regenerates the oxime on gentle warming with alkalis; if, on the other hand, the oxime is boiled 1 hr. with 2 parts Ac_2O and a little NaOAc and poured into dil. soda, it gives *o*-diacetylamino-sym-m-xylenyl methyl ether, $\text{Ac}_2\text{NMe}_3\text{C}_6\text{H}_4\text{OMe}$, flat needles from dil. MeOH or benzine, m. 80–1°, converted by boiling aq. or alc. alkalis into the *monoacetyl derivative*, prisms from C_6H_6 or needles from H_2O , m. 150.5°, which is also obtained from the oxime in Et_2O treated with an equiv. amt. of PCl_5 and ice; it is attacked by boiling alc. alkalis only with difficulty and is also quite stable towards hot HCl ; in fact, it is obtained when the oxime is heated at 100° in sealed tubes with concd. HCl . *o*-Aceto-sym-m-xyleneol (b) is prepd. like its Me ether, except that the reaction mixt. need not be cooled; when the evolution of HCl ceases, an amt. of AlCl_3 equal to that originally used is added and the mixt. is heated 1 hr. on the H_2O bath. Some (c) is always formed and passes over in the last portions of the steam distillate. The yield of (b), m. 57–8°, b_{18} 140–1°, is generally 60–70%. With alk. Me_2SO_4 it gives the Me ether above. *Oxime*, flat needles and prisms from dil. MeOH , C_6H_6 or PhMe , m. 143°; *semicarbazone*, crystals from alc. or C_6H_6 , m. 217–8°. Boiled with Ac_2O and NaOAc the oxime gives an oil, probably a tri-Ac deriv., which with alc. alkalis loses AcOH and becomes alkali-sol., acids then pptg. *o*-acetylamino-sym-m-xyleneol, scales from H_2O , m. 186–7°, which with boiling moderately concd. HCl (1:1) is hydrolyzed to the free $\text{H}_2\text{NMe}_3\text{C}_6\text{H}_4\text{OH}$, only little of the ethenyl base (see below) being formed. The *N*-Ac compd. is also formed when the oxime in AcOH is satd. with HCl gas; some of the free NH_2 compd. is formed as by-product. *Ethenyl-o-amino-sym-m-xyleneol*, $\text{Me}_2\text{C}_6\text{H}_3\text{N}:\text{CMe}_2\text{O}$, is the chief product when the oxime is rear-

anged with PCl_5 ; it solidifies to needles, m. 28.5°, b. 234–6°, has a penetrating characteristic odor; *hydrochloride*, long needles from H_2O , m. 139° (decompn.), easily hydrolyzed when heated; *nitrate*; *sulfate*; *chloroplatinate*; *chloromercurate*, flat needles from very dil. HCl . The base is also formed, together with $\text{H}_2\text{NMe}_3\text{C}_6\text{H}_4\text{OH}$, when the oxime is heated with concd. HCl in sealed tubes at 100°. *o*-Amino-sym-m-xyleneol, best obtained by heating 10 g. of the above oxime with 100 cc. each of HCl and H_2O until the crystals first formed redissolve, treating with steam for a short while to remove the ethenyl base, filtering hot and concg. to incipient crystn. of the HCl salt and pptg. from the latter in hot H_2O with NH_4OH , soda, NaOAc , or, best, Na_2SO_3 ; it crysts. from C_6H_6 in needles, m. 158–9°; *hydrochloride*, crystals from hot H_2O or dil. HCl , m. 270–80°, depending on the rate of heating, stable in light and air when dry. *Sodium salt*, from the base rubbed with NaOH , dissolves in H_2O but soon hydrolyzes and a yellow oxidation product soon begins to sep. *Dibenzoyl derivative*, felted needles from MeOH , m. 148–9°; gentle warming with alc. alkali gives the *N*-monobenzoyl derivative, crystals from MeOH or dil. alc., m. 211–2°. *o,o*-Diaceto-sym-m-xyleneol (c) has been obtained in 66% yield of the (a) used (systematic expts. on the best method of prepn. have not yet been carried out) by slowly adding with cooling 60 g. AlCl_3 to 10 g. (a) and 25 g. AcCl in 150 cc. CS_2 , gently warming 1 hr., distg. off the solvent, decompg. with HCl and ice, drying on clay and crystg. from benzine or MeOH ; it m. 109–10°. *Dioxime*, plates from C_6H_6 , m. 173–4°. *p*-Benzeneazodiacetoxyleneol, from (c) and 3 mol OH treated with an equimol. amt. of PhN_2Cl , allowed to stand some time

and acidified with AcOH, ruby-red crystals or flat needles from benzine, m. 138-9°. *Acetate*, $\text{Me}_2\text{Ac}_2(\text{PhN}_2)\text{C}_6\text{OAc}$, orange needles from MeOH or C_6H_6 ; treated in 20 parts alc. alternately with Zn dust and AcOH until decolorized, filtered and dild. with H_2O , it gives the *hydraso acetate*, silky needles from alc., m. 175-6°, insol. in alkalis. *2-Hydroxy-4,6-dimethylbenzaldehyde*, needles from dil. MeOH, m. 48-9°, sol. in alkalis with yellow color, gives a violet color with FeCl_3 , is obtained in small yield when 20 g. $3,5\text{-Me}_2\text{C}_6\text{H}_3\text{OH}$ (*d*) in 50 g. NaOH and 50 g. H_2O at 60-70° is treated with 40 g. CHCl_3 , heated for some time, steam distd., the distillate extd. with Et_2O , the ext. shaken several hrs. with concd. NaHSO_3 , the product decompd. with soda and again steam distd. The residue from the 1st steam distn. on cooling deposits a considerable amt. of $2,6,4\text{-Me}_3(\text{HO})\text{C}_6\text{H}_2\text{CHO}$, m. 190°; its Me ether, obtained by methylation of the HO compd., seps. from low-boiling petr. ether in needles, m. 45-7° (Gattermann, C. A. 2, 820, gives 18°). Nitration of 20 g. of (*d*) gives about 6 g. of *o*-nitro-*sym-m*-xyleneol, lemon-yellow needles from ligroin or dil. MeOH, m. 66°, volatile with steam, and a larger amt. of the *p*-nitro compound, yellowish prisms from ligroin, m. 107-8°. The *o*-compd. heated 3 hrs. at 160-70° with 1 mol. BzCl gives the *benzoate*, flat prisms from ligroin, m. 71-2°, reduced by Zn and AcOH to the $3,5,2\text{-Me}_2(\text{BzNH})\text{C}_6\text{H}_3\text{OH}$ above. *p*-Nitroso-*sym-m*-xyleneol, from a very dil. soln. of (*d*) and NaNO_2 in cold NaOH treated slowly with dil. AcOH and allowed to stand 24 hrs., prisms from alc., m. 182-3°. (*d*) in cold AcOH slowly treated with 1 mol. Br in 10 parts AcOH gives *p*(*p*)-*bromo-sym-m*-xyleneol, flat needles from ligroin or C_6H_6 , m. 115-6°, couples in alk. soln. with PhN_2Cl to a brown-yellow substance insol. in alkalis. Some di-Br compd. and unchanged (*d*) are also obtained. Using 2 mols. Br, the product is the *o,p*-*dibromo compound*, crystals from low-boiling petr. ether, m. 73-4°, while in more concd. soln. with the calcd. amt. of Br is obtained the tri-Br compd., m. 165-6°. CHAS. A. ROUILLER.

Formation of mono- and disazo compounds from phenols and phenol ethers. K. V. AUWERS AND E. BORSCHÉ. Marburg. Ber. 48, 1716-30(1915); cf. C. A. 8, 2389.—It was previously found in the study of mono- and dialkylphenols and their ethers that in general their coupling ability increases with the number of alkyl groups and that *m*-alkyls have the greatest influence. It has now been found that a 3rd alkyl has not much influence while an *o*-Ac group considerably decreases the coupling ability; tetra-alkylphenols and even $3,5,2,6\text{-Me}_4\text{Ac}_2\text{C}_6\text{HOH}$ couple as readily as simpler phenols. With the ethers a 3rd alkyl slows up the coupling somewhat and a 4th strongly impedes it. The coupling expts. were carried out in the same way as in the earlier work. *sym-m-Xyleneol isopropyl ether*, from the xyleneol and 1 mol. iso-PrONa digested 0.5 hr. in iso-PrOH on the H_2O bath, then heated 6 hrs. in sealed tubes with 1.5 mols. iso-PrBr, b. 208-10°; 2 g. coupled with azophor red yielded 2 g. *p*-nitrobenzeneazoxyleneol isopropyl ether, brown-violet needles from ligroin, m. 92-3°. *sym-m-Xyleneol allyl ether* (*a*), from the xyleneol and 1 mol. NaOEt in alc. boiled with the calcd. amt. of allyl bromide to the neutral point, b_{11} 109°; *p*-nitrobenzeneazo compound, flat, brown-red needles from benzine. *Isopseudocumenol methyl ether*, from the phenol and Me_2SO_4 , b. 213-6°; *p*-nitrobenzeneazo compound, brown-red leaflets, m. 130-2°. From 1 g. $2,3,5\text{-AcMe}_3\text{C}_6\text{H}_2\text{OH}$ and 1 mol. PhN_2Cl allowed to stand 1.5 days in cold 1% NaOH are obtained 0.95 g. *p*-benzeneazo-*o*-aceto-*sym-m*-xyleneol, orange needles from petr. ether, m. around 94°, easily sol. in aq. alkalis, and 0.34 g. of the *o,p*-disazo compound, brown needles from alc., m. 169-70°; similar expts with the Me ether gave mostly unchanged ether with small amts. of red, tarry products after several days. *o*-Ethyl-*sym-m*-xyleneol, from the *o*-Ac compd. with amalgamated Zn and HCl in 75% yield, flat needles from petr. ether, m. 80-1°, gives a greenish color with FeCl_3 ; methyl ether, b_{11} 110°. From 1 g. of the phenol is obtained 0.39 g. of the *p*-benzeneazo compound, bright red, flat needles from petr. ether, m. 119-20°, and 0.7 g. of the disazo compound, brown needles with golden

luster from alc., m. 148-9°, while the Me ether after 2.5 days yields 50% of *p*-nitrobenzeneazo-*o*-ethyl-sym-*m*-xlenol methyl ether, brown-red needles from benzine, m. 120-1°. *o*-Allyl-sym-*m*-xlenol, from (a) heated under a reflux condenser until the temp. of the liquid no longer rose, shaken with alkali repeatedly and distd. *in vacuo*, b₁₇ 135-6°, needles from low-boiling petr. ether, m. 50.5°, gives no color with FeCl₃; methyl ether, b₁₉ 116°. From 1 g. of the phenol is obtained 0.44 g. of the *p*-benzeneazo compound, red needles from petr. ether, m. 94-5°, and 0.81 g. *disazo* compound, violet-brown felted needles from alc., m. 132-3°; the Me ether in 2.5 days gives 24% of the *p*-nitrobenzeneazo compound, brown needles without luster from benzine, with bluish luster from MeOH, m. 94-4.5°. *o*,*o*-Diaceto-sym-*m*-xlenol methyl ether, prisms from dil. MeOH, m. 71-2°, does not couple with azophor red. The phenol is reduced by Zn-Hg and boiling HCl in 1.5 days to *o*,*o*-diethyl-sym-*m*-xlenol (60% yield), flat needles from low-boiling petr. ether, m. 88°, gives no color with FeCl₃; methyl ether, yellowish oil, b₁₀ 116-8°; ethyl ether, obtained with NaOEt and EtI, yellow oil, b. 254-5°. *p*-Benzeneazo compound of the phenol, red needles from petr. ether, m. 126-8°; *p*-nitrobenzeneazo compound, obtained after 2 days in AcOH and NaOAc, brown needles from benzine, m. 168-70°. *p*-Nitrobenzeneazo-*orcinol* 3-methyl ether, obtained almost quant. from the components in AcOH after 3 days, dark red needles with bluish luster from AcOH, m. 225-6°; dimethyl ether, also obtained almost quant. in the same way, silky red-brown needles from alc., m. 100-1°. *p*-Benzeneazo-sym-*m*-xylidine, from 3 g. xylidine, 7 cc. of 10% HCl, 50 cc. of 0.5 *N* PhN₂Cl and 8.32 g. NaHCO₃ allowed to stand several days, thin red needles from benzine, m. 67°. *p*-Benzeneazo-*vic*-*m*-xylidine, from the components in the above proportions and subsequent boiling of the crude product with HCl to destroy the admixed diazoamino compd., flat brown needles with bluish luster from benzine, m. 99-101°. *p*-Benzeneazo-*vic*-*o*-xylidine, ruby-red prisms from benzine, m. 96.5-7.5°.

Structure of tyrosine (GEAKE) 11A. Magnetochemistry of inner-complex compounds (LIFSCHITZ) 2.

II. BIOLOGICAL CHEMISTRY.

WILLIAM J. GIES, EDGAR G. MILLER, JR., PAUL E. HOWE.

A. GENERAL.

FRANK P. UNDERHILL.

Note on tyrosine. A. GEAKE AND M. NIERENSTEIN. Univ. Bristol. *Biochem. J.* 9, 309-12(1915).—G. and N. confirm their previous statement (*C. A.* 8, 3801) that tyrosine is not methylated by diazomethane in ethereal suspension. This is in accordance with their findings with other amino acids, and has led them to accept the "betaine" formula for these acids (see Meyer and Jacobson, *Lehrb. organ. Chem.* 2, ii,

733(1913)): $R-CH \begin{array}{c} \text{NH}_2 \\ \diagup \quad \diagdown \\ \text{CO} \quad \text{O} \end{array}$. To express the influence that the N atom has on the hydroxyl radical (see Meyer and Jacobson), the following formula is suggested for

can be methylated on acylation, when the "betaine" ring is opened (C. A. 8, 3563), the action of diazomethane on glycytyrosine was studied in relation to its action on tyrosine hydroxyls in caseinogen. The glycytyrosine methyl ester (A) was obtained, showing that the nitrogen atoms of the glycytyrosine still have an

the conclusion that the tyrosine hydroxyls in methylocaseinogen are not methylated by diazomethane. B. HOROWITZ.

The origin of the glucosamine obtained in the hydrolysis of *Boletus edulis*. WINIFRED ROSS. Univ. St. Andrews. *Biochem. J.* 9, 313-9(1915).—The action of concd. HCl on the fungus *Boletus edulis* produced glucosamine-HCl; glucosamine was not produced by H₂SO₄. The suggestion is made that the glucosamine thus isolated is derived from a complex, of the nature of glucoprotein, containing carbohydrate and amino residues, and that it does not exist in the form of a glucosamine glucoside.

B. HOROWITZ.

Reducing enzymes of dried yeast (Lebedev) and of rabbit muscle. A. HARDEN AND R. V. NORRIS. *Biochem. J.* 9, 330-6(1915).—The property of dried yeast (Lebedev) of reducing methylene blue, lost by washing, can be restored by treatment with the following substances: salicylaldehyde, benzaldehyde, anisaldehyde, isovaleraldehyde, phloroglucinol, dihydroxyacetone, glycolic acid, citric acid, glyceric acid, succinic acid, bouillon, boiled yeast ext., normal horse serum, acid sterile milk. The suggestion that these substances are capable of acting as acceptors for the O activated during the reduction process (cf Harden and Norris, C. A. 8, 3059) is not borne out by the fact that several of the following substances, all of which are without effect, are easily oxidizable: quinol, *p*-phenylenediamine, pyrogallol, resorcinol, citral, glycerol, propyleneglycol, 2,3-butyleneglycol, formic acid, acetaldehyde, glucose, levulose, glyccoll, alanine, tyrosine, malic acid, tartaric acid, mandelic acid, yeast nucleic acid, creatine, asparagine, guanidine-acetic acid, guanidine nitrate, glycol, Witte peptone, acetone, pyruvic acid, and methylglyoxal. Lactic acid, either as free acid or as the Na salt, was very active. Glycolic, glyceric, and citric acids produce slow reduction. Attempts to establish a quant. relation between the amts. of methylene blue reduced and the amt. of lactic acid oxidized, failed. Acetaldehyde was one of the oxidation products formed. This suggests that the lactic acid is first converted to pyruvic acid, and that the latter is then decomposed by the carboxylase of the washed yeast into CO₂ and acetaldehyde which, being incapable of further oxidation under the conditions of the expt., could be detected in the liquid. Minced muscle of the rabbit, washed several times with saline soln., behaves similarly to dried yeast, in that it loses the power of reducing methylene blue. Acetaldehyde reactivates washed muscle, though it has no effect on washed yeast. The expts. on muscle are being continued.

B. HOROWITZ.

The supposed synthesis of uric acid from its decomposition products by tissue extracts. HENRY M. SPIERS. Univ. Cambridge. *Biochem. J.* 9, 337-41(1915).—The author repeated the expts. of Ascoli and Izar (C. A. 3, 2011; 4, 1055) in which ox liver ext. was used. Na urate was added to this, and it was aerated and incubated.

Ascoli and Izar claim that this operation destroys the uric acid, but S. finds that on satg. the resulting mixt. with an inert gas such as CO_2 , H, or N, or by merely incubating the product in a closed vessel, the uric acid is quantitatively regenerated. Further, Ascoli and Izar, in attempts to det. what substances give rise to uric acid, found that dialuric acid and urea combined to form uric acid in presence of ox liver ext. under anaërobic conditions. S. failed to get any of these results. B. H.

The role of fluorine in the animal organism. G. BV. KAMPEN. *Chem. Weekblad* 12, 225-32(1915).—Mainly a discussion of A. Gautier's paper on this subject (*C. A.* 8, 1451). J. T. FLOHL.

The action of pectase. N. G. BALL. *Sci. Proc. Roy. Dublin Soc.* 14, 349-57 (1915).—Pectin was obtained from the roots of the carrot by mincing them and heating on the water bath for 2 hrs. to coagulate the albuminous substances. The pulp was squeezed out, the liquid treated with $\text{H}_2\text{C}_2\text{O}_4$ to ppt. the Ca^{++} and the pectin sepd. by addition of an equal vol. of alc., filtered off, redissolved in hot H_2O and then re-pptd. by more alc. In this way, about 0.3 g. pectin was obtained from 1100 g. carrots. Before use the pectin was dild. with H_2O to a 2% soln. and toluene was added as a preservative. Sap pressed from leaves of *Syringa vulgaris* was used as a source of pectase. The elec. resistance of a mixt. of pectase and pectin remained practically const. for over 2 hrs., thus proving that a true gel was formed. The viscosity of similar mixts. was measured at different temps. and it was found that the enzyme is much more active at 14° than at 0° although at 21° its activity had diminished, due possibly to the use of a different pectase soln. The viscosity increased slowly at first, then more rapidly until a max. was reached and this was followed by a rapid decrease. An increase in the amt. of electrolytes present lowered the max. while a decrease in the electrolytes raised it. The decrease in viscosity is probably to be explained by the action of the electrolytes in clumping together the particles of colloid forming the reticulum of the gel so that a suspension is produced. It appeared that the coagulation of pectin consists of 2 processes: gelification and subsequent coagulation of the gel. Gelification and coagulation are due to a minute trace of electrolytes. As far as gelification is concerned, the action of electrolytes is probably indirect and it may be that their presence is necessary in order to allow the enzyme to exert its activity. The coagulation of pectin is explained thus: Pectic acid is produced by the action of pectase on pectin. If electrolytes are absent, the mixt. remains liquid, but if any ions are present, partial pptn. of colloid takes place. At first these colloidal particles will be free from one another but as action of the pectase proceeds a semi-solid reticulum is built up. If electrolytes are present in large amount, clumping together of the particles of colloid takes place and a suspension is formed with a consequent diminution in viscosity. A max. viscosity will be reached when the rate of gel-formation becomes insufficient to counterbalance the clumping effect.

R. L. SIBLEY.

Studies on substances with specific action produced by various organs. I. Compounds which exert an influence upon the development and condition of definite tissues. EMIL ABDERHALDEN. *Univ. Halle. Arch. ges. Physiol.* 162, 99-128(1915).—Various organs were digested step by step with enzymes, (pepsin and HCl, and pancreatic and intestinal juices being used); the degree of digestion was followed with the biuret reaction and the $\text{NH}_3\text{-N}$ estns. Organs were then chopped fine, ground, and with NaCl soln. and dried. Parts were concd. *in vacuo*, and sterile solns. prepared with H_2O . Several problems were studied, such as the influence of the exts. upon the development of the remaining organs after certain or the development of growing animals.

Tadpoles were used as subjects. The thyroid, thymus, ovary and pituitary were used, alone and in various combinations. The thymus and thyroid glands contain substances which influence in a characteristic way the development of tadpoles. This indicates that the substances which influence development do not belong to the group of proteins or peptones. If they are derivs. of proteins they must belong to the simpler decompn. products or to definite components (amino acids?). The results are shown by a series of photographs.

C. J. WEST.

A labile form of protein and its relation to living protoplasm. OSKAR LOEW. *Biochem. Z.* 71, 306-20(1915).—A very labile form of protein compd. is found in many plant cells, usually in the cell juices, but in some cases also in the cytoplasm. This labile form differs from the ordinary proteins in that it is pptd. by NH_4OH and org. bases, usually undergoing at the same time a rapid change into a stable compd. This pptn. is not of the nature of neutralization. While very active bases ppt. the protein as small granules, weak bases like caffeine and antipyrine not only do not destroy the life of the cell but also do not change the labile character of the protein. The small droplets which first appear gradually unite to large refractive drops (caffeine-proteosomes) often having half the diameter of the cell and sometimes reaching 30μ in diameter. The changes which the labile form undergoes are easily followed under the microscope. The coagulation of the labile form consists in the elimination of water with the formation of a mass with a hollow space, a hollow sphere, or an amorphous unformed mass. HCN , NH_4OH and N_2H_4 produce the same result. The action of NH_3 produces a solid mass without the formation of the hollow spaces. The labile active protein behaves towards dyes in the same way as the living protoplasm, while the proteosomes coagulated by heat, alc., acids or spontaneously act like dead protoplasm. The intimate relationship between the reserve labile protein and the organized labile protein or living protoplasm has been demonstrated in several ways.

C. J. WEST.

Osmotic equilibrium between blood, milk and bile. F. H. VAN DER LAAN. Utrecht. *Biochem. Z.* 71, 289-305(1915); cf. *C. A.* 9, 2391.—Milk and bile have the same osmotic concn. as the blood from which they are secreted. The f. p. depression of normal ox blood is between 0.53 and 0.57° . It is independent of the kind of food. Hunger of a few days has no effect upon the f. p. of the blood or of milk formed. It is possible by suitable diln. of the contents of the intestine to decrease the value of Δ for the blood, or to increase it by feeding large amts. of Glauber's salt. The similarity between the f. ps. of milk and blood remains, even under these abnormal conditions. The f. p. method is the best for detecting watered milk. If a milk has a higher f. p. than 0.53° it must be considered as watered.

C. J. WEST.

Use of blood as human food and the behavior of formaldehyde in the organism. E. SALKOWSKI. Univ. Berlin. *Biochem. Z.* 71, 365-90(1915); cf. *Berl. klin. Wochschr.* 1915, Nos. 12 and 23.—Ox blood has nearly the same protein content as the best fat-free beef. The nutritive value of ox blood is equal to that of beef. Blood may be kept several weeks by use of boric or salicylic acids or by formalin. Blood preserved in this way is not directly utilizable for food but the blood protein prepd. from it in the usual way is utilizable. A method that leads to the direct use of the preserved blood—except by the addition of large amts. of sugar—is not known. Perhaps MeCl is suitable (based on expts. on milk). Coagulated blood protein may be kept unchanged for months in CHCl_3 water and 0.5% formalin. The CHCl_3 which adheres to it is easily removed. Blood coagulated by heat may be preserved unchanged for a long period by the addition of formalin. This may also be accomplished, to a less degree, by addition of large amts. of sugar. The addition of 0.6 to 1.0 g. formalin to the daily food of a dog of 12 kg. was easily tolerated; the utilization of the protein of the food was not influenced. About 0.6% of the formalin, the remainder being con-

pletely oxidized. The poisonous effect of HCHO when used internally is very much overestimated, exhaustive expts. are needed to serve as a basis for its therapeutic use. If one distills the urine of a dog fed with flesh and fat or with flesh, fat and rice, after the addition of 2% H_2SO_4 , the distillate gives the CHI_3 test. This is also true of human urine. The mother substance is not known; it cannot always be hydroxymethylfurfural, and may be in part lactic acid.

Isolation of glucosamine hydrochloride from the mucoid of ascites fluid. ADOLF OSWALD. Zurich. *Z. physiol. Chem.* 95, 100-1(1915).—Six l. fluid gave 1.3 g. mucoid, which, when hydrolyzed with 40 cc. 3% HCl for 1.5 hrs., gave a soln. that reduced Fehling soln., and finally deposited crystals. These gave the tests of glucosamine-HCl. No analyses are given.

C. J. WEST.

Crystallization of human serum albumin. ADOLF OSWALD. Zurich. *Z. physiol. Chem.* 95, 102-3(1915).—Serum albumin was obtained from ascites fluid by crystn. from satd. $(NH_4)_2SO_4$ and dil. H_2SO_4 .

STANLEY R. BENEDICT.

Urochromogen and diazo reactions. M. LEVY. *Deut. med. Wochschr.* 41, 1212-3 (1915).—It is concluded that the agreement of the urochromogen reaction with the diazo reaction is very general. Only exceptionally did these reactions fail to coincide.

S. AMBERG.

Preliminary note on the preparation of collodion dialyzers of graded permeability. WILLIAM BROWN. Imperial Coll. of Science and Technology, London. *Biochem. J.* 9, 320(1915).—Collodion dialyzers, constant in character, and of a wide range of permeability, may be obtained by treating air-dried collodion membranes with varying percentages of alc. in water. The permeability of the membrane is directly related to the strength of the alc. used. A second method of prep. graded dialyzers, depending on a process of differential drying, has also been worked out. A detailed account of these expts. is promised shortly.

B. HOROWITZ.

Picric acid and benzidine stain; a transitional cell in general paralysis. B. LEMCHEN. *Med. Rec.* 88, 787(1915).—L. describes a modification of his stain as previously reported (*C. A.* 9, 3080). This stain permits the differentiation of a new cell, differing from others in its lack of granules, and in its homogeneity and eccentric nucleus. The cell appears in cases of paralytic insanity.

A. H. RAHR.

The phenoltetrachlorophthalein test of liver function. MAX KAHN AND JAMES R. JOHNSTON. *N. Y. Med. J.* 102, 848-50 (1915).—The test was applied to 34 patients suffering from hepatic and other diseases. The irregularity of results led to the conclusion that the procedure is not of clinical value. A. H. RAHE.

Potassium permanganate in the examination of cerebrospinal fluid. A. J. RUBENSTONE. *N. Y. Med. J.* 102, 1052 (1915).—If the quantities of fluid and KMnO_4 employed by Boveri (cf. *C. A.* 8, 3199) are doubled, the test is increased in delicacy. A series of more than 100 tests showed that there exists a definite ratio between the rapidity with which the reaction takes place and the degree of abnormality of the fluid.

A. H. RAHE.

A new method for the study of plant nutrients in sand cultures. A. G. MCCALL. *J. Am. Soc. Agron.* 7, 249-52 (1915).—Granite-ware pots 12 × 12 cm., which hold about 1500 g. of sand, were used in plant physiological studies. Hemispherical clay funnels having a smaller diameter than the rim of the pot are placed on the surface of the sand. The seeds are planted in a circle around the pot between the edge of the funnel and the rim of the pot. The pots are provided with tubes at the bottom so that the nutrient solns. which are added through the funnel at the top can be drawn off at the bottom. This is done by suction. By this method of growing plants in sand with nutrient solns., the solns. can be changed without disturbing or shocking the root system.

J. J. SKINNER.

Estimation of sugar in the urine. Estimation of very small amounts of sugar by a time reaction. F. CLAUSNIZER. Stuttgart. *Arch. ges. Physiol.* 162, 159-86 (1915).—This is a modification of Worm Muller's test (*Arch. ges. Physiol.* 27, 113 (1882)). Dil. the protein-free urine to a density of 1.005 at 15°. Pipet 25 cc. into a test tube 160 mm. × 18 mm., add 3 drops 30% NaOH and a small amt. of kieselguhr, shake and filter. Place 4.5 cc. of the clear filtrate in a test tube 140 mm. × 16 mm. and add 0.5 cc. of a sterile 0.2% glucose soln. and a drop of litmus. Treat this mixt. with 10% AcOH until the soln. is red and then add 3 drops more. Prep. second tube with 2.5 cc. alk. Rochelle salts and 2 cc. 5% CuSO_4 soln. Heat both tubes 60 sec. with shaking, allow to stand 20 sec., then mix and shake. The number of seconds which elapse before the appearance of the sugar reaction is a measure of the amt. of sugar present. A table is given of the amt. of sugar corresponding to the number of seconds.

C. J. WEST.

Simple method for the quantitative determination of very small amounts of potassium. H. J. HAMBURGER. Groningen. *Biochem. Z.* 71, 415-63 (1915).—The method consists of the detn. of the vol. of the ppt. formed by adding a Co soln., $\text{Co}(\text{NO}_3)_2 \cdot 3\text{K}(\text{NaNO}_2) \cdot n\text{H}_2\text{O}$, and centrifuging. Five cc. of the soln. (containing not more than 0.02 g. K) are treated with 1.5 cc. of a Co soln. (made by mixing 6 vols. of a soln. of 50 g. $\text{Co}(\text{NO}_3)_2$ in 100 cc. H_2O and adding 25 cc. AcOH and 10 vols. of a soln. of 50 g. NaNO_2 in 100 cc. H_2O) at room temp. and then allowed to stand 16 hrs. at 37°. After cooling to room temp., the fine orange yellow or yellow cryst. mass is centrifuged to const. vol. in a special tube and the vol. read. The capillary, 0.04 cc., is divided into 100 parts, of which 1 part is equal to 0.0001 g. K, irrespective of the concn. of the K in the liquid. There is complete proportionality between the amt. of K and the vol. of the ppt. It is necessary to keep the relation between the solns. 5:1.5, so that if 10 cc. of the soln. of K are used, 3 cc. of the Co soln. should be used. The presence of large amt. of Na does not influence the result. The same is true for Ca, Mg, and SO_4 , but H_3PO_4 must not be present except in small quantity. The H_3PO_4 may be removed by a mixt. of CaCl_2 - $\text{Ca}(\text{OH})_2$ or by magnesia mixt. One cc. of the filtrate is sufficient for an analysis. It is suggested that ppts. may be estimated by using a centrifuge.

Investigations on combustion in the lungs with remarks on the determination of the gases of the blood. V. HENRIQUES. Univ. Copenhagen. *Biochem. Z.* 71, 481-94 (1915).—Satisfactory duplicate analyses can be obtained of the gases pumped out of defibrinated or oxalated blood if care is taken to keep the blood in motion while the portion is being drawn (in order that the blood corpuscles may not ppt.) and if the blood is drawn quickly. The duplicates are not so satisfactory if the blood is taken slowly from animals which have been previously injected intravenously with hirudin. This is due to the gradual settling out of the corpuscles. Samples of blood from the right heart and from the pulmonary artery simultaneously have the same CO_2 and O content. Blood from the right heart thus corresponds in compn. to that which circulates in the lungs. A study of the gas content of the blood in the lungs and of the respiration gases demonstrates that there is no combustion taking place in the lungs.

C. J. WEST.

Estimation of small amounts of sugar in the urine. S. NAGASAKI. Univ. Utrecht. *Z. physiol. Chem.* 95, 61-77 (1915).—The approx. amt. of urine necessary to reduce 10 cc. Cu soln. is detd. Slightly less than this amt. is then added to 10 cc., the soln. boiled 5 min., and then small amts. added each min. until the reduction is complete. The amount required contains 20 mg. glucose. The true glucose content is detd. by fermentation. The detn. is not affected by the addition of milk or cane sugar. The content of "isomaltose," calcd. as glucose, is detd. by heating the urine after fermentation with 2% citronic acid, and fermenting. The same value is obtained by heating the urine with 1% HCl for 10 min., and then fermenting. The method is applied to a study of glucose ingestion in the human organism.

C. J. WEST.

Occurrence of arginase in the animal organism and its detection by means of the formol titration. S. EDLBACHER. Heidelberg. *Z. physiol. Chem.* 95, 81-7 (1915).—Sorensen's formol titration is a suitable and very reliable means for detecting arginase. It is to be preferred to the earlier method of Kossel and Dakin. As far as has been studied by E., arginase is found only in the liver; it is absent in the liver of birds and reptiles, as earlier observed by Clementi. It was not found in the kidneys of birds. Kossel and Dakin reported arginase in the kidney, thymus and intestine. This could not be confirmed by the present method. The results are the same whether the organ contains blood or not. The addition of serum to inactive organ suspensions and press juices did not activate the arginase action.

C. J. WEST.

Colorimetric estimation of uric acid in the blood. H. F. HÖRST. Univ. Christiania. *Z. physiol. Chem.* 95, 88-99 (1915).—Five cc. blood are weighed into a tared porcelain dish containing about 50 mg. K oxalate. 35 cc. H_2O , 5 drops 2% AcOH and 1 cc. HCHO soln. (35% HCHO, dild. with an equal vol. H_2O and neutralized with NaOH) are added, and the mixt. heated to boiling; 1 cc. AcOH is then added, the mixt. boiled 3-4 min., filtered, and the residue washed with 50 cc. H_2O . The filtrate is treated with 5 cc. 50% AcOH, and concd. to 1 cc. This is transferred to a centrifuge tube, the dish washed out with 2 cc. 0.1% Li_2CO_3 soln., and the soln. treated with a previously prepared mixt. of 20 drops concd. NH_4OH , 8 drops 3% Ag lactate soln. and 4 drops magnesia mixt. This is allowed to stand overnight, is then centrifuged, decanted, the residue washed with 3 cc. H_2O , and then treated with 6 drops freshly prepd. H_2S soln., 1 drop 50% AcOH and 3 cc. H_2O . This is then heated carefully until the H_2S is driven off, again centrifuged, the liquid transferred to a 25 cc. flask, washed out with 3 cc. H_2O , and then 2 cc. phosphotungstic acid (Folin) and 5 cc. satd. Na_2CO_3 soln. added and the mixt. made up to 25 cc. This is compared with a standard soln.

C. BACTERIOLOGY.

ERNEST D. CLARK.

"Reaction" of bacteriologic culture media. W. M. CLARK. Wash. *J. Infect. Diseases* 17, 109-36(1915).—The H-ion concns. of various culture media after the addition of successive quantities of alkali and acid have been determined by the H electrode. From the data so obtained, titration curves were plotted which show (1) the amt. of acid or alkali which it is necessary to add to a given medium in order to bring about a given H-ion concn. such as would be indicated by a certain tint of phenolphthalein; (2) the buffer effect of various media at various H-ion concns. of different media adjusted to various degrees of reaction. Adjustment of different media to the same degree of reaction (Fuller's result in media having widely different H-ion concns. The "standard" result calculated from a titration the proper quantity of alkali to be added) is shown to be more vitiated by the practice of titrating media while hot. C. indicates the advisability of abandoning this method and substituting a colorimetric method. Data are presented showing the influence upon the H-ion concn. of oxidation-reduction and pptn. of proteins when accelerated by high temps. A discussion of the significance of the proper adjustment of the H-ion concn. of media is given.

The characteristics of bacteria of the colon type occurring on the coast of Washington. W. M. CLARK AND A. C. EVANS. Washington, D. C. *J. Infect. Diseases* 17, 137-59(1915).—By means of exact gas analyses on accurately obtained cultures, the ratio of the volumes of CO_2 and H_2 evolved during the anaerobic fermentation of glucose was detd. on 166 cultures of colon-like bacteria obtained from 35 localities from various localities. Of these cultures 151 gave CO_2/H_2 ratios varying from 1.0 to 3.0, and were thus sharply distinguishable from cultures from bovine sources. Other biochemical tests confirmed the distinction. Seven interesting cultures gave CO_2 only (the summary incorrectly says hydrogen only).

The differentiation of bacteria of the colon-aerogenes family by titration of H-ion concn. W. M. CLARK AND H. A. LUBS. Washington, D. C. *J. Infect. Diseases* 17, 160-73(1915); cf. preceding abstr.—The H electrode has been applied to the determination of H-ion concn. in various cultures of the group during the development of the metabolism of different species were detected. By simple means the H-ion concn. can be so adjusted that the final H-ion concns. diverge widely for the different species and these differences can then be sharply distinguished by means of *p*-nitrophenol or methyl red. This method gives results for this group of bacteria in accordance with the gas-ratio method.

The germicidal properties of dental cements. M. R. SMIRN. *Dental Cosmos* 57, 1209-28(1915).—The cements examined were (I) a black cement, (II) a red Cu_2O cement, (III) a white Cu cement, (IV) a light yellow cement, (V) a ZnO or oxyphosphate cement. The germicidal action of each cement as powder, plastic or loose pellet, "set" or "unset," inserted in extracted carious teeth was studied; the bacteria used were *Staphylococcus pyogenes aureus* and *B. coli*; at times *Streptococcus pyogenes*, *Staphylococcus aureus* and *B. anthracis* were also used. The mixing fluids possessed very different antiseptic properties due to their H_3PO_4 content. The antiseptic action of the cements was due to sol. compds. Loose or plastic pellets owed their germicidal power entirely to the excess of H_3PO_4 required to be added in mixing. Of the cements (II) apparently possessed germicidal power *per se*; the others showed the slight power they showed to the excess of mixing fluid required. The power of the best of the cements (I and II) was equal only to 1:50,000.

stroy *B. anthracis* even after one week, but destroying *Staphylococcus aureus* after two or three days. Used as pellets in carious teeth, cement (II) showed by far the best germicidal powers. With respect to germicidal power, the cements fell into two classes: the more efficient, (I) and (II), and the less efficient, (III), (IV) and (V). The germicidal efficiency depends considerably on the mixing fluid and on readily sol. constituents of the cement. In actual use, the germicidal action may be in part mechanical. For technic, reference must be made to the original paper. JOSEPH S. HEPBURN.

The value of hypochlorous acid in the treatment of gas gangrene. JOHN FRASER. *Brit. Med. J.* 1915, II, 525-9.—An application of "Eupad" and "Eusol" introduced by Lorrain Smith (*C. A.* 9, 2919). A. H. RAHE.

The utilization of certain pentoses and compounds of pentoses by *Glomerella cingulata*. L. A. HAWKINS. *Am. J. Botany* 2, 375-88(1915).—In these expts. on the effect of the fungus *Glomerella cingulata* upon pentoses and compds. of pentose sugars it has been shown that the amt. of material yielding furfural in the apple is decreased when the apple is rotted by this fungus. The decrease is brought about by the action of the fungus on the compds. in the apple which contain pentoses. These compds. are broken down and the material yielding furfural is used by the fungus. In the process the alc.-sol. furfural-yielding material is increased which indicates that the pentose sugars are split off from the compds. in which they exist in the fruit. The fungus is able to utilize either glucose, xylose, arabinose, arabin or xylan as a sole source of C. The 3 sugars are most efficiently utilized, xylose perhaps the best. The fungus grows better on xylan than on arabin. The filtered ext. of the fungus mycelium is able to act on xylan under aseptic conditions with the formation of an alc.-sol. substance, which reduces Fehling soln., forms furfural when boiled with HCl and possesses other properties of xylose. This ability of the ext. is lost on boiling. The breaking down of the xylan takes place gradually and the alc.-sol., furfural-yielding material is found to increase the longer the ext. acts upon the xylan, the rate being more rapid during the early part of the action. A cryst. compd. was obtained from the alc.-sol. portion of the prepn. of xylan which had been acted on by the ext. of the fungus mycelium. This compd. was apparently xylose. It is evident that there is a xylanase present in the ext. of fungus mycelium which hydrolyzes xylan to xylose. J. J. SKINNER.

D. BOTANY.

CARL L. ALSBERG.

Occurrence of manganese in wheat. WM. P. HEADDEN. Colo. Agr. Exp. Sta. *J. Agr. Research* 5, 349-55(1915).—Mn seems to be present in wheat wherever grown, irrespective of the conditions of soil and climate. In the wheat kernel it is present in about the same proportion as Fe, though Fe greatly predominates in soils. Fertilizers applied to the soil did not affect the amount of Mn stored in the kernels. Variation in the quantity of water supplied, from 1 to 3 feet, did not affect the amount of Mn in the grain. It seems improbable that a nonessential mineral constituent of plants would occur in all samples and in nearly the same quantity under such a variety of conditions. A short bibliography is given. W. H. FRY.

The role of ash elements in the life of plants. M. A. EGOROV. *Russ. J. Exp. Landw.* 16, 270-80(1915).—In experiments with castrated and uncastrated oats, it was observed that the former remained green nearer the time of maturation. This is probably explainable on the ground that Mg has not been removed from the sphere of the vital functions of the plants and carried to the grain as would be the case with uncastrated plants. W. H. FRY.

Some relations of plants to distilled water and certain dilute toxic solutions. M. C. MERRILL. *Am. J. Pharm.* 87, 549-55(1915); see *C. A.* 9, 2103. W. G. G.

Transmission by grain of effects of castration in stalks of corn. E. HECKEL. *Compt. rend.* 161, 338-40(1915).—The saccharin character of cornstalks appears to be transmitted during 4 years of male castration, practiced in a continuous line; and in general, the effect of castration is to increase the sugar content sometimes to double that of the non-castrated stalks. It is advised to proceed with the castration about 14 days after the appearance of male inflorescence. L. W. RIGGS.

The question of the toxicity of distilled water. R. P. HIBBARD. *Am. J. Botany* 2, 389-401(1915).—Distd. H_2O made by first shaping tap H_2O with animal charcoal and then distg. and redistg. first with H_2SO_4 , then $Ba(OH)_2$, was used for growing seedlings of *Lupinus albus*. Best growth took place in cultures in which the H_2O was changed 4 times each day. Cultures in which the H_2O was not changed developed roots similar to roots injured by dil. solns. of toxic salts. The roots were thick, short, blunt and crooked near the tip. The author concludes that the plant roots excrete a substance that inhibits growth. J. J. SKINNER.

An extension to 5.99° of tables to determine the osmotic pressure of expressed vegetable saps from the depression of the freezing point. J. A. HARRIS. *Am. J. Botany* 2, 418-9(1915).—The tables for this extension are given. The tables of the value of $P = 12.060\Delta - 0.021\Delta^2$ for f. p. lowering of 0.01° to 2.99° are given in a previous article (*Am. J. Botany* 1, 73-5(1914)). J. J. S.

Calcium hypochlorite as a seed sterilizer. J. K. WILSON. *Am. J. Botany* 2, 420-7(1915).—A soln. made by using $CaCl_2$, in proportion of 10 g. to 140 cc. of H_2O , allowing to stand several hrs., and decanting off the clear liquid, was used as a seed sterilizer. The soln. contains about 2% Cl, and the vol. employed was 5 times more than the vol. of seed. The time required for sterilizing varied with the kind of seed. For *Medicago sativa* it required 6 hrs. while *Frisolium pratense* required 24 hrs. The data shows that the time required in most cases for sterilizing seed and the exposure necessary to produce injury are many hours apart. This allows considerable latitude with respect to the time during which the disinfectant may be allowed to act. A table is given showing the time required for sterilizing and the time required to cause injury to the various kinds of seeds. The efficiency of the method was tested by inoculating various seeds, which had been sterilized, with a pure culture of *Bacillus radicola*; after 45 days only a few cases showed signs of contamination. The method offers a way for securing sterile plantlets for physiological expts. and also for eradicating such plant diseases as may be controlled by treating the seed. A convenient table is given, enumerating the different chemicals found to be best suited for sterilizing different kinds of seed, together with the investigators. J. J. SKINNER.

Acid accumulation and destruction in large succulents. E. R. LONG. *Plant World* 18, 261-72(1915).—The acidity of the sap of *Echinocactus wislizeni* and *Carnegiea gigantea* is higher in early morning than at sunset, the acids formed in the metabolism of carbohydrates tending to accumulate during the night and being partially destroyed by higher temp. and photolysis on the succeeding day. The acidity of the sap of these species following the nightly accumulation of acids is higher in the outer than in the inner region. The diurnal difference in acidity of the sap becomes smaller in successive zones as the center of the plant is approached, being as much as 50% in the exterior and slight in the innermost tissues. In the outer parts where carbohydrates are plentiful, sugar metabolism is great and acid production and nightly acid accumulation are large. In the innermost tracts of tissue carbohydrates are less plentiful, acid production is correspondingly less, and the increasing insulation as the center is approached tends to minimize diurnal temp. and light differences, so that in these parts diurnal differences in acidity are small. The movement of sap of low acidity from the central cylinder to the peripheral layers of these thick succulents has little effect upon

the acid content of these tracts, while variations of great amplitude result from the conjoint action of light and temp. J. J. SKINNER.

Organic nutrition of green flowering plants. TH. BOKORNY. *Biochem. Z.* 71, 321-64(1915).—Many plants can assimilate methyl alc., methylal and glycerol.

C. J. WEST.

Plant enzymes. IV. Invertase of the leaves of potatoes. P. DOBY. Magyarovar. *Biochem. Z.* 71, 495-500(1915); cf. *C. A.* 9, 476, 1190.—The enzymes were isolated by pressing the leaves and centrifuging the green or black liquid. The presence of the enzyme was shown by the fact that the liquid was not stable towards heat, and that the reaction showed the character of a monomol. reaction. The value of k was proportional to the concn. of the enzyme. The juice which was obtained with the lowest pressure showed the greatest activity. C. J. WEST.

F. PHYSIOLOGY.

ANDREW HUNTER.

Influence of hypertonic salt solution upon blood pressure. KARL RETZLOFF. *Z. exp. Path. Ther.* 17, 161-84(1915).—Results obtained by replacing blood in the organism with hypertonic NaCl solns. of different concns. lead to the conclusion that the increased blood pressure observed is due to the ion content of the salt soln.

A. H. RAHE.

Postural albuminuria of children. L. JEANNERETTE. *Arch. med. enfants* 18, No. 9(1915); *J. Am. Med. Assoc.* 65, 2039.—J. shows by extensive tests that albuminuria is brought on in children by standing still. The combination of lordosis, orthostatism and muscular immobility induced albuminuria in 49% of the children examd. The findings in various groups of children are listed in 12 tables. L. W. RIGGS.

Human milk. ALFRED W. BOSWORTH. New York Agr. Expt. Sta., *Tech. Bull.* 43, 3-5(1915); cf. *C. A.* 9, 1637.—The acidity of human and cow milk is practically the same and the practice of adding lime water to modified cow milk used for infant feeding as a means of correcting the acidity is thus shown to have no foundation.

R. C. ROARK.

Influence of food and exercise upon the blood sugar. W. VON MORACZEWSKI. Zürich. *Biochem. Z.* 71, 268-88(1915).—When fed during a period of insufficient food, carbohydrates increase the amt. of blood sugar. Proteins produce a smaller but more permanent increase. If an excess of food is given, carbohydrates have no influence upon the amt. of blood sugar while proteins and fats cause a very slight but long continued increase. With a carbohydrate or gelatin diet, exercise increases, and with a diet of flesh or fatty foods lowers the amt. of blood sugar. This is true for normal individuals. In diabetics and people with a tendency towards glucosuria, muscular exercise increases the amt. of blood sugar no matter what the diet may be. Tolerance for sugar is increased by muscular exercise; in diabetics, in spite of the increased blood sugar, muscular exercise leads to a decreased excretion of sugar.

C. J. WEST.

Studies on the physiology of coagulation. Influence of alkalis and acids. Action of several protein-precipitating agents. A new theory of the method of coagulation. E. HERZFELD AND R. KLINGER. Univ. Zürich. *Biochem. Z.* 71, 391-405(1915).—The optimal reaction for the formation of thrombin is neutral or bicarbonate alkaline. Alk. reaction retards the action of thrombin (pptn. of fibrin), while acid accelerates it. Many other agents that ppt. proteins are favorable to the action of thrombin. Attempts were made to apply the theory of Herzfeld as to the soly. and pptn. of proteins to the process of coagulation. It is shown that the stability of solns. of fibrinogen is

considerably influenced by certain protein decompn. products (especially fibrin peptone).
C. J. WEST.

Note on the immediate effects of reduction of kidney substance. H. T. KARSNER, H. A. BUNKER, JR., AND G. P. GRABFIELD. Harvard Med. School. *J. Exp. Med.* 22, 544-50 (1915).—The removal of approx. 0.16 of the kidney substance causes no marked alteration in the amt. of the non-protein N of the blood or urine, although there is a slight tendency toward accumulation in the blood for a period of 24 hrs., and an increased output in the urine for a period of 48 hrs. This is probably due to the operation. Excision of 0.5 of the total kidney substance was followed, in one case, by a distinct accumulation of non-protein N in the blood during the 1st 24 hrs., associated, however, with anuria, while in a 2nd case there was no accumulation and no anuria. The output of non-protein N for the 1st 48 hrs. appears to be diminished, again showing a slight tendency towards accumulation for, at the most, 48 hrs. The removal of approx. 0.66 of the kidney substance was followed by a very slight increase in output and, after 24 hrs., a slight but distinct increase in the amt. of non-protein N in the blood which lasted for 3 days. The reduction of the kidney substance to approx. 0.33 does not prevent the remaining fragment from excreting urine in normal amts. and concns.

G. PATHOLOGY.

H. GIDRON WELLS.

Investigation of toxins and antitoxins. I. Partial synthesis of antitoxins. I. I. OSTROMUISLENSKII. *J. Russ. Phys. Chem. Soc.* 47, 263-300 (1915); cf. *C. A.* 9, 3090. —O. begins with giving his views on the nature of toxins and antitoxins and their interaction with each other. Chemically most of the toxins are nitrogenous substances of high mol. wt., feebly basic properties and colloidal nature, while the antitoxins are colloidal, amphoteric, and are either varieties of the same globulin or nearly related globulins having the same structure. Towards toxins the antitoxins act like weak acids, forming salts which, unlike alkaloidal salts or the salts of cryst. poisons, are innocuous. Unlike acids, however, each antitoxin possesses a specificity in that it is capable of neutralizing only a particular toxin. The specificity is due not to a particular chem. constitution, but to a particular phys. state of the colloidal antitoxin mols., such as the nature of their surface (as in the passivity of certain metals caused by formation of films on their surface), size, mass, elec. condition, possibly also configuration and number of mols. per colloidal particle. These phys. characteristics distinguish antitoxins from ordinary globulins which under ordinary conditions do not react with toxins. The assumption that the specificity of antitoxins is not due to chem. constitution is based upon the consideration that if such were the case the existence of an unreasonably large number of isomeric antitoxins would have to be assumed. The interaction of an antitoxin with the corresponding toxin is supposed to take place in 3 stages: (1) Mutual adsorption (intimate phys. contact) due to the above specific characteristics; (2) chem. neutralization, made possible only by this intimate contact, with the formation of a non-poisonous salt readily decomposable by acids or alk.; (3) gradual profound change of this salt due either to intramol. forces or to the effect of the surrounding medium, with the result that the salt ceases to be decomposable by acids or alkali. The last change takes place only upon prolonged standing (from 4 hrs. to weeks, months or years according to the nature of the salt). Having enunciated these views, O. proves by expts. that when an ordinary globulin is placed in conditions that enable it to adsorb a toxin it is converted into the corresponding antitoxin which then neutralizes the toxin. By decomp. the resulting salt with HCl a mixt. is obtained which contains the toxin taken and the antitoxin corresponding to it. The adsorption of toxins by globulins may be induced by various catalyzers (I, ICl_4 , CS_2) of which the

most convenient is a 6% soln. of NaCl. Thus by keeping a mixt. of the serum of horse blood containing 6% of NaCl and either diphtheria toxin or botulism toxin for 36 hrs. at 37° the resulting product lost all toxicity, but upon acidulation with HCl was proved to contain the toxin taken and the antitoxin corresponding to it. The sepn. of toxins from antitoxins may be accomplished in several ways: Gelatin permits toxins to pass through much faster than antitoxins; CaOCl₂ destroys toxins but does not affect antitoxins; digestion at 68° destroys antitoxins only, etc. Work is in hand for prepg. *in vitro* the antitoxins of cobra poison, cholera and other poisons. The conversion of globulin into an antitoxin by adsorption of the corresponding toxin in the presence of catalyzers readily explains the phenomenon of immunization of animals, as well as the fact that a small amt. (1 unit) of a toxin administered to a horse yields a large amt. (100,000 units) of the corresponding antitoxin. The animal fluids (blood, milk, etc.) doubtless contain various catalyzers which cause the natural globulins of these fluids to adsorb the administered toxin, thus changing it to the corresponding antitoxin. Nutrition and the physiological functions of the organism constantly change the reaction of the fluids from neutral to acid or alk. or *vice versa*. This splits up the salt-like combination of toxin and antitoxin, enabling the former to convert fresh portions of globulin into antitoxin. In just as plausible a manner is the fact explained that a subcutaneous injection of a toxin mixed with certain substances (I, ICl₂, etc.) is almost perfectly harmless, though in this case no immunization can take place. These substances merely act as catalyzers, immensely accelerating the adsorption of toxin by globulin, thus quickly producing the corresponding antitoxin. O.'s method makes it possible quickly to obtain any amt. of an antitoxin from a very small amt. of the corresponding toxin without the use of animals. Mere digestion of a globulin (horse blood serum) with the given toxin and alternate acidification and neutralization will bring about the result. The great advantage of this quick and cheap method of prepg. antitoxins over the usual immunization method is obvious, the latter requiring in some cases 16 months and frequently causing the death of the animals. Other advantages are: The needed antitoxin may always be had in fresh condition; it may be obtained from the blood serum of the patient himself; it ought to be possible to obtain certain antitoxins under conditions which are fatal to animals, such as the use of free Cl or I as catalyzers. or of temps. as high as 60°. Owing to the fact that some amorphous alkaloids (ricine and abrine) resemble toxins in their ability to produce antibodies in animals, while on the other hand cryst. toxins (cobra toxin) resemble alkaloids in forming poisonous salts, O. thinks there is no radical difference between alkaloids and toxins, so that it ought to be possible to induce the alkaloids to produce antialkaloids that would act as antidotes of the former in the same manner as the toxins produce their own antitoxins. All that is necessary to accomplish this result seems to be the polymerization of the alkaloids to amorphous colloidal substances. Initial steps in this direction are already to be found in the literature. The 1st alkaloid O. intends to attack with this aim in view is piperine (cf. *J. Chem. Soc.* 79, 922). II. New attempts to convert albuminous substances into specific antitoxins. I. I. OSTROMUISLENSKII AND D. I. PETROV. *Ibid* 301-7.—Continuing the work on the conversion of globulins into antitoxins (cf. above), it is shown that when horse serum is inoculated with a culture of diphtheria bacilli or with *Bac. botulinus* very little toxin is to be found in the liquid, owing to its adsorption in nascent state by the globulin of the serum, but its amt. greatly increases upon acidification with HCl. The absorption of toxin by the globulin is, however, incomplete, even in presence of a large amt. of free globulin. This is most probably due to the alkalinity of horse serum. Attempts to bring about greater adsorption by neutralizing the serum failed, there being no formation of toxins at all under these conditions. It was observed that the serum containing diphtheria toxin becomes much more active through diln. (with physiol. NaCl soln.). This is possibly due to disso-

ciation into toxin and antitoxin. III. Danyasz phenomenon. I. I. OSTROMUISLENSKII. *Ibid* 307-13.—When a toxin is treated with the equiv. amt. of the corresponding antitoxin, adding the former to the latter not all at once but in small portions at a time, the biologic neutralization of the toxin is incomplete, the resulting liquid remaining toxic (Danyasz phenomenon, *Ann. Pasteur* 16, 331(1902)). After discussing the numerous explanations of this phenomenon given by various authors and rather severely criticizing Ehrlich's views on this subject for its maze of unnecessary hypotheses of side-chains, haptophores, toxoids, toxones, etc., O. shows that his theory of the nature of the interaction of toxins with antitoxins (cf. above), in connection with the explanation given by the French school, readily accounts for D.'s phenomenon. The 1st step in the above interaction being mere adsorption, the difference in the effect of antitoxin on toxin according to whether the latter is added all at once or in successive portions is like that in treating pieces of filter paper with a dye in soln. When all the pieces are immersed together into the soln. they are all dyed the same tint, but when immersed one after the other the 1st pieces receive a much greater amt. of dye than the subsequent ones, and with a large number of pieces the last ones may even remain colorless. In the same way the 1st portions of toxin adsorb an amt. of antitoxin greater than their chem. equiv., so that the subsequent addition of toxin leaves some of it in free condition. That in D.'s phenomenon the toxin undergoes no chem. change as is supposed by some authors is shown by the fact that the acidification of the final liquid with HCl gives a soln. of the same degree of toxicity as corresponds to the total amt. of toxin taken. IV. New reaction for the characterization of toxins. I. I. OSTROMUISLENSKII. *Ibid* 313-7.—O.'s method of converting globulins into antitoxins (cf. above) may be used quickly to det. whether a given poison will produce in animals the corresponding antibody. For this purpose 3 cc. of the poison are mixed with 3 cc. of normal serum, to the liquid 0.36 g. of pure NaCl is added, and the whole set aside for 3-36 hrs. at 37°. In case an antibody is produced the liquid will become atoxic. It is advisable to carry out a blank expt. leaving out the serum. A negative result would therefore save time, expense and unnecessary slaughter of animals. The method was applied with positive results to the toxins of tetanus, diphtheria and botulism, and negative to morphine and strychnine. H. M. GORDIN.

Isolation of vegetable agglutinins by means of their isoelectric point. G. A. BROSSA. Berlin. *Arch. sci. med.* 39, 241-50(1915).—Many colloids have been pptd. by Michaelis and his co-workers at their iso-electric points. The method was tried out on the agglutinin derived from the fungus *Agaricus campestris* and it was found that this was most completely pptd. at a-H ion concn. of 2.6×10^{-4} . Lactic acid, in the presence of Na lactate, was used as the pptg. agent. The ppt., dissolved in a few drops of a mixt. of 1 part N/3 NaH_2PO_4 and 3 parts Na_2HPO_4 , showed about 0.5 the activity of the original ext., the result being partly due to the incomplete pptn. even at the isoelectric point and partly due to the alteration of the ppt. in contact with the soln. M. HEIDELBERGER.

Iodine content of the thyroid gland in various stages of life and in various pathological conditions. RINALDO PELLEGRINI. Padova. *Arch. sci. med.* 39, 276-316(1915).—There is no constant relation between the macroscopic development of the gland and the quantity of I contained in it. The av. dry substance is 22.5% of the wt. of fresh gland; it is higher in young people and in cases of death from fibrinous pneumonia, lower in old age and in tuberculosis. In individuals dying between 45 and 55 yrs. the values for I are highest; they are lowest in those who do not reach 15 yrs.; individual variations are, however, very great. The amt. of I does not depend upon the state of nutrition. There is an increase above the average in cases of sudden death, cirrhosis of the liver, and in acute inflammatory processes of the intestine, while a de-

crease is noted in tuberculosis, especially in advanced ulcerative forms, in pregnancy and child-birth, in anemia, in inflammations of the lungs, in pellagra, and in chronic inflammatory processes of the intestines. In a number of other diseases no changes could be noted, and in all cases individual variations were very great.

M. HEIDELBERGER.

Sandfly fever and bacteriology. C. J. STOCKER. *Brit. Med. J.* 1915, II, 503-4.—Vaccine treatment with a possibly non-specific organism gave inconclusive results. Complement deviation tests and animal expts. did not indicate that a specific causative agent had been used.

A. H. RAHE.

Hemolytic action of urine in certain conditions. C. S. MCKEE. Vancouver. *Brit. Med. J.* 1915, II, 596-8.—*Method.* One cc. of blood suspension (1 drop of blood to 4 cc. physiol. NaCl soln.) is mixed with 15 drops of the urine to be tested, and incubated for 2½ hrs. The cell emulsion is best prepd. as for the Noguchi-Wassermann test. The extent of hemolysis is measured by titration. Fifteen drops of urine are used as the test quantity, since additional urine will not change the result if hemolysis is not obtained with this amt. The laking action is not purely a question of quantity; a small amt. of urine may give a reaction more quickly than a larger amt. of the same sample. [This is evidently a colloidal reaction due to dilution. See Buxton and Rahe, *J. Med. Res.* 15, 113(1909); *Ibid* 311; *Ibid* 17, 483(1910).—ABSTRACTOR.] Incubation is a necessary part of the procedure and hemolysis occurs with both acid and alk. urines. The reaction is obtainable with urine from cases of erysipelas, gout, acute rheumatic fever, advanced tuberculosis, certain cases of syphilis, and in other conditions, but does not occur with normal urine. Urine, alk. at time of passage, becomes active only after standing at room temp. for 3 or 4 hrs. but the activity does not increase upon prolonged standing (24-48 hrs.). Acid urines lose in activity after standing 24-48 hrs. even though they do not become alk. To produce hemolysis with acid and alk. urinary compns., it is necessary to use these, added to salt soln. or normal urine, in far greater amts. than exist in hemolytic urines. When NaHCO₃ is added to either acid or alk. hemolytic urines, laking does not occur. The agent causing the hemolysis is apparently not a constituent of normal urine.

Experimental studies on the immunity conferred by diphtheria toxin-antitoxin mixtures. BRUNO BUSSON AND ERNST LÖWENSTEIN. *Serotherap. Inst., Vienna. Z. exp. Path. Ther.* 17, 289-310(1915).—In guinea pigs a higher degree of immunity is obtained with large doses of neutralized or slightly over-neutralized toxin-antitoxin mixts. than with a smaller amt. of partly neutralized toxin. In rabbits neutralized, and in goats partly neutralized, toxin gives the best results. The immunity conferred by neutral and slightly over-neutralized mixts. is to a considerable extent directly proportional to the degree of tissue absorption. Active and passive immunity in the guinea pig appears in 30-40 days and reaches its optimum in 59 days. Under-neutralized mixts., which produce no immunity when freshly prepd., become active after storage (1-2 months in ice chest). Rabbits develop a lesser degree of immunity than guinea pigs or goats. Tubercular guinea pigs do not exhibit increased sensitiveness to toxin-antitoxin mixts.

A. H. RAHE.

Blood cryoscopy and blood urea. MARTIN KROTOSZYNER AND GEO. W. HARTMAN. San Francisco. *J. Am. Med. Assoc.* 65, 1788-92(1915); cf. *J. Am. Med. Assoc.* 60, 188. and *C. A.* 7, 3979.—While the cryoscopic test requires strict attention to detail, when the technical difficulties are mastered the results are surprisingly uniform, and the test becomes in experienced hands an exact index of renal function. The following conclusions are given: Blood cryoscopy and blood urea run parallel in cases with normal renal function. Both tests show high points with renal insufficiency. The limited range between normal and pathologic points, while rendering the technic of cryoscopy more difficult, increases its delicacy and prognostic significance. The application of both tests intensifies in doubtful cases the significance of the findings.

Deposition of calcium soaps in the liver. R. HAGIWARA. *Basel. Centr. Path.* 26, 481-5(1915).—In the liver of a man dying in diabetic coma there was found extensive deposition of Ca, often in relation to the fat vacuoles, and according to microchem. reactions in the form of Ca soaps. Test for phosphates was not made. No explanation was found for the condition.

H. G. W.

Studies on aleucocytic animals. I. Analysis of the action of antibacterial sera and chemotherapeutic agents. II. Contribution on natural resistance to swine erysipelas. LIPPMANN. Koch Inst., Berlin. *Z. Immunität.* 24, 107-22(1915).—It is possible by intravenous injection of a bacteriotropic serum (Neufeld's pneumococcus serum) to prevent passage of the pneumococci into the blood vessels, but animals rendered free from leucocytes by Th develop bacteriemia in 8 hrs. at the latest; therefore pneumococcus serum can prevent sepsis only in the presence of leucocytes. A bacteriolytic serum (cholera) shows in aleucocytic animals, which still possess complement, the same bacteriolytic action in the Pfeiffer expt. as normal animals; therefore the leucocytes are not essential for bacteriolysis. Protozoa are destroyed as completely with salvarsan in the absence of leucocytes as in normal animals, but ethylhydrocuprein does not protect against bacteriemia in the Th animals and hence requires coaction of the body. Th-treated guinea pigs show a greater resistance than normal ones

to the bacteria of swine erysipelas, which is ascribed to the liberation of bactericidal substances from the leucocytes.

H. G. W.

The Wassermann reaction in rabbits after treatment with luetic liver extracts. HJALMAR EIKEN. Copenhagen. *Z. Immunität.* 24, 188-98(1915).—After injection of aq. exts. of luetic livers the W. reaction is positive in rabbits, generally but not always disappearing in a short time. Alc. exts. of aq. exts. of luetic liver will produce W-reactions, but this reaction is not obtained with alc. exts. of normal human heart or non-luetic infant liver. Passage through a Chamberland filter deprives the aq. exts. of their activity. The active rabbit sera do not give the Hermann-Perutz reaction.

H. G. W.

Observations on the coagulation reaction in lues. L. HIRSCHFELD AND R. KLINGER. Univ. Zürich. *Z. Immunität.* 24, 199-219(1915).—Globulin solns. shaken or diluted with water, which give positive Wassermann reactions or are themselves antihemolytic, increase the activity of exts. containing cytozyme. This is ascribed to adsorption of the cytozyme on the surface of the particles, which increases its activity. Active serum inhibits more than inactive, and serum that has been treated with bacteria inhibits less than before. After digestion with kaolin a positive coagulation reaction appears. The mixt. of a luetic serum with inactive acetone ext. can be recognized with complement, but not with platelet cytozyme; therefore the phenomenon of cytozyme activation is shown only by definite ppts. with surfaces of certain but undefined character. The reduction in coagulation activity of the ext. on reaction with luetic serum may be ascribable to a globulin pptn. which surrounds the particles in the exts. The greater delicacy of the coagulation reaction in lues may be due to the fact that the active reacting principle (lipoid) is identical with the indicator (cytozyme), while in the Wassermann reaction only the complement acts as indicator and the alterations are shown indirectly. Cf. C. A. 9, 469.

H. G. W.

Normal leucotoxins and their relations to phagocytosis and consanguinity. LEOPOLD LÖHNER. Univ. Gratz. *Arch. ges. Physiol.* 162, 129-58(1915).—Heterologous undil. serum (rabbit, guinea pig, swine, goat, sheep, ox, human) influences the carbon phagocytosis of horse leucocytes, causing a diminution of the % of phagocytes. Heat inactivation of the serum (0.5 hr. at 55.5°) decreased the diminution of the phagocytosis considerably but never increased phagocytosis. This diminution is due to the content of normal leucotoxins in the serum. The estn. of the carbon phagocytosis diminution is a safe means for the detection of toxin action where other methods give, in part at least, negative results. Normal leucotoxins are complex, thermolabile serum constituents. Certain observations seem to indicate that even in inactivated serum, specific leucotoxic bodies, thermostable substances, are present in small amts. In the main the phagocytosis decrease in inactivated serum is the result of the differences in the chem. constitution, especially perhaps in variations in the Ca^+ and OH^- ion content. The normal leucotoxins of different kinds of sera, measured by the degree of diminution of phagocytosis, are different. The toxin titer of sera of different individuals of the same species shows considerable variations, in many cases even greater than the differences of species. This leads to the conclusion that there is not a complete parallelism between the action of leucotoxins and the blood relationship of different organisms. The parallelism consists in the fact that the toxin action is the stronger the more distantly the species are related. The absence of a cytotoxic effect may not always be taken as a proof of an established blood relationship, nor is the presence of this action a proof of a marked diversity.

New observations on beri-beri. Conclusions. H. SCHAUMANN. *Arch. Schiffs- u. Tropen-Hyg.* 19, 425-45(1915).—A review, with 95 references (1911-1915).

C. J. WEST.

Acidosis and its regulation in the human body. A. BEGUN, R. HERRMANN AND E. MÜNZER. *Prag. Biochem. Z.* 71, 255-67(1915).—It has been shown experimentally and clinically that acids, when introduced into the human organism as such, or when produced pathogenically, are neutralized by NH_3 and excreted as NH_4 salts in the urine. A change in the CO_2 -tension of the venous blood does not occur during this process. Decreased CO_2 -tension cannot serve as a measure of acidosis unless the other factors are simultaneously controlled. The CO_2 content of the venous blood decreases in prolonged acidosis because of the absence, after some time, of substances in the blood which can bind CO_2 , and perhaps also because of alterations in the tissues. Further investigation is needed to show the role of respiration. The CO_2 -tension of the alveolar air is, in part, dependent upon the CO_2 content of the venous blood and, in so far, is probably a function of the capacity of the blood to bind CO_2 . The CO_2 -tension of the venous blood can thus sink in the absence of acids; the extent and duration of this fall remain to be detd. C. J. WEST.

Ferment action. XXIV. The serum ferments and antiferment during pneumonia. JAMES W. JOBLING, WILLIAM PETERSEN AND A. A. EGGSTEIN. *Vanderbilt Univ. J. Exp. Med.* 22, 568-89(1915); cf. *C. A.* 9, 3095.—The crisis in pneumonia is usually accompanied by (a) decrease in the amt. of serum antienzyme, (b) the mobilization of a non-specific protease in the serum, (c) an increase in amount of serum lipase, (d) a decrease in the amt. of non-coagulable N and of the proteoses in the serum. The crisis is associated with the beginning of an active autolysis, depending upon an altered enzyme-antienzyme balance. The fibrin and leucocytic debris must be considered as potential sources of toxic substances. With rapid autolysis proceeding, only non-toxic materials are absorbed. **XXV. Serum changes following kaolin injections.** *Ibid* 590-6.—The intoxication produced by the intravenous injection of inert substances such as kaolin is due to protein split products derived from the serum proteins. The kaolin acts as an absorbing medium for the serum antienzyme causing an alteration in the enzyme-antienzyme balance. The intoxication is accompanied by an increase in the amt. of serum protease and proteoses. The serum lipase, the amino acids and the total non-coagulable N show relatively little change. The amt. of antienzyme shows an initial increase, followed by a loss. **XXVI. The effect of protein split products on the serum ferments and antiferment.** *Ibid* 597-602.—In dogs the toxic effect of primary proteoses is usually associated with the following serum changes: (a) an increase in amt. of serum anti-enzyme followed by a fall in titer, (b) some increase in amt. of serum protease, (c) an increase in serum lipase, (d) a decrease in serum proteoses and amino N. Secondary proteoses produce (a) less marked changes in the anti-enzyme titer, (b) a marked increase in amt. of serum protease, (c) an increase in serum proteoses, (d) only a slight change in serum lipase, (e) a primary decrease in amino N. The peptone used (prepd. from dog muscle) caused a change in anti-enzyme titer similar to that produced by the primary proteoses, a marked increase in amt. of serum protease, only a slight change in serum lipase, a primary decrease in proteoses followed by an increase, and an increase in amino acids. A very small dose of peptone resulted in a decrease in anti-enzyme titer, together with a primary decrease in serum protease. The peptone prepn. was non-toxic when introduced into the stomach or rectum, while injection directly into the lumen of the small intestine was followed by immediate intoxication. **XXVII. The effect of killed bacteria on the serum ferments and antiferment.** *Ibid* 603-11.—The intravenous injection of killed organisms is followed by the mobilization of a non-specific protease and lipase. The rapidity and extent of this reaction depends upon the toxicity of the organism and on the resistance of the organism to proteolysis. The temp. and leucocytic curve bear no relation to the enzyme change. The amt. of serum antienzyme is usually increased after the in-

jection. Of the organisms studied, the typhoid bacilli produced the most marked enzyme changes and the tubercle bacilli the least. The toxicity of the dried organisms cannot depend wholly upon proteolysis *in vivo* but must depend in part on the pre-formed toxic substances liberated on lysis. Serum protease should not be considered as the sole exciter of intoxication through the production of protein split products; it seems possible that its function may in part be one of detoxication. **XXVIII.** The acceleration of esterase action. JAMES W. JOBLING, A. A. EGGSTEIN AND WILLIAM PETERSEN. Vanderbilt Univ. *J. Exp. Med.* 22, 701-6(1915).—K citrate, K oxalate, and Ca lactate accelerate the action of tissue and serum esterases. Intravenous and intraperitoneal injections of large amts. of Na citrate do not cause a definite increase in the activity of the serum esterase. **XXIX.** The relation of serum esterase to liver destruction. *Ibid* 707-12.—Liver tissue showing fatty degeneration, obtained from animals poisoned with P or CHCl_3 , contains a decreased amt. of esterase. The serum of animals poisoned with P or CHCl_3 has a high esterase activity. The increased amt. of esterase in the serum is not derived from the disintegrating liver cells, as the esterase in the blood of the hepatic vein is less in amt. than that found elsewhere.

C. J. WEST.

Relation of the spleen to blood destruction and regeneration and to hemolytic jaundice. **XII.** The importance in the production of hemolytic jaundice of the path of hemoglobin to the liver. J. HAROLD AUSTIN AND O. H. PERRY PEPPER. Univ. Penn. *J. Exp. Med.* 22, 675-81(1915).—When hemoglobin is set free in the portal circulation a larger amt. is held by the liver and converted rapidly into bile pigment than is the case when it is set free in the general circulation; under the former condition overloading of the liver with bile pigment more readily occurs and jaundice is more apt to develop. This mechanical influence must, therefore, be a factor in the lessened tendency, after splenectomy, to the jaundice which follows blood destruction due to hemolytic agents. A large number of cells undergo their final disintegration in the spleen, after the action of hemolytic poisons, and the hemoglobin there liberated passes directly to the liver. When the spleen is removed, this disintegration occurs in other organs, notably in the lymph nodes and bone marrow, and the hemoglobin passes into the general circulation and reaches the liver more gradually and in a more dilute form. **XIII.** The influence of diet upon the anemia following splenectomy. RICHARD M. PEARCE, J. HAROLD AUSTIN AND O. H. PERRY PEPPER. *Ibid* 682-93.—The anemia which develops after splenectomy is most marked in animals on a mixed table scrap diet of meat, bread, cereals, and vegetables, which is essentially a cooked diet. Control studies in which a unilateral nephrectomy precedes splenectomy demonstrate that the anemia is not due to operation, hemorrhage, or accidents of convalescence but develops only in the absence of the spleen. The results of studies of the influence of food containing a large amt. of iron in presumably easily utilizable form, as in raw beef spleen, do not support the view that the anemia is due to lack of iron in the food. Observation on the influence of a diet of raw meat as contrasted with cooked meat shows a more severe anemia in animals on the cooked diet and suggests the possibility that heat alters some substance which, in the absence of the spleen, the body cannot utilize.

C. J. WEST.

The influence upon the spleen and the thyroid of the complete removal of the external function of the pancreas. J. E. SWEET AND JAMES W. ELLIS. Univ. Penn. *J. Exp. Med.* 22, 732-8(1915).—The complete removal of the function of the pancreas concerned in digestion is followed by marked changes in the spleen and in the thyroid apparatus. The spleen shows an extreme simple atrophy. The thyroid apparatus exhibits a constant change shown by the macroscopic transparency of the gland, by the microscopic increase in the amt. of colloid, by the chem. increase of the iodine

content of the gland, and by the functional test of the delayed appearance of tetany after the complete removal of the thyroid apparatus. C. J. WEST.

An experimental study of blood glucolysis. The effects of thyroid and adrenal extracts and phlorhizin on glucolysis *in vitro*. GEORGE M. MACKENZIE. Columbia Univ. *J. Exp. Med.* 22, 757-65(1915).—Blood glucolysis *in vitro* during a period of 3 hours' incubation proceeds at practically the same rate under sterile conditions as when no effort is made to prevent contamination. Fresh thyroid extract, epinephrine, and phlorhizin, do not contain any substances which have a const. effect upon the rate of blood glucolysis outside of the body. No evidence of the presence of an anti enzyme was found. C. J. WEST.

Diet and tumor growth. WILLIAM H. WOGLOM. Columbia Univ. *J. Exp. Med.* 22, 766-79(1915).—Lactose does not increase the receptivity of mice and rats for the transplantable carcinomata of their species. C. J. WEST.

Relationship of chronic protein intoxication in animals to anaphylaxis. WARFIELD T. LONGCOPE. Columbia Univ. *J. Exp. Med.* 22, 793-9(1915).—Such foreign protein as horse serum and egg-white in the amts. employed in these expts. do not produce evidences of intoxication immediately after injection into rabbits. Single large injections do, however, produce changes in the parenchymatous organs after a period of 10 to 21 days. These develop at the time or immediately after the animal has formed antibodies for the foreign proteins. The mechanism of the development of the lesions in the myocardium, liver, and kidneys of rabbits is thus the same, whether a single inoculation is given or whether repeated inoculations are made in sensitized animals. By the latter method, however, much more marked and extensive changes may be produced. C. J. WEST.

Bilirubin. HANS FISCHER. Univ. München. *Z. physiol. Chem.* 95, 78-80 (1915).—The possibility of bilirubin occurring in the urine in combination with protein is discussed. All samples thus far examd. contain small amts. of S (0.08-0.94%), which may be derived from protein. This was not removed by boiling with glacial AcOH for 2 hrs. Because of this the more probable formula for bilirubin is the one with 33 C atoms. C. J. WEST.

Immunization with autogenous proteins in bronchial asthma. HENRI ISKOWITZ. *N. Y. Med. J.* 102, 950-3(1915).—In the prepn. of the protein, 60 cc. of bronchial secretion, drawn from the bronchus by means of a bronchial catheter, is sterilized by heat, concd. to a gelatinous mass on the water bath and 60 cc. of physiological salt soln. added. 0.25% phenol is added as a preservative. The filtered soln. is injected in graduated amts., the first dose being 0.5 cc. of the prepn. dild. 1:10. A. H. R.

H. PHARMACOLOGY.

ALFRED N. RICHARDS.

Poisonous gases. E. KOHN-ABREST. *Ann. fals.* 8, 215-39(1915).—Toxic gases and vapors may be roughly divided into 3 groups: (I) irritants, (II) poisons, (III) those possessing both of these properties. The most important irritants are: Cl, HCl, Br, HBr, HI, SO₂, and NO₂. These injure because of their distinctive effect on the mucous membranes, and cannot as a rule be detected, after death, in the victim by chem. means. To the second class belong those gases which act like chem. poisons and which remain in the organism in traces and can usually be identified chemically. In this group are CO, H₂S, H₂Te, AsH₃, PH₃, (CN)₂, HCN and CS₂. Group III contains COCl₂, CNCl, H₂Se. Data upon the physical properties and physiological and toxicological effects of each of the gases are given in detail, and incompatibles and active absorbents suggested. As a summary is given a table showing the d., wt. per l., color, temp. and pressure of liquefaction, and toxicity of each substance. H. S. BAILEY.

Emetine in the treatment of periodontal suppurations. ALLEN J. SMITH AND M. T. BARRETT. Univ. Penna. *Dental Cosmos* 57, 1201-9(1915).—Symbiosis of *Entameba gingivalis* Gros and bacteria in the pockets of pyorrhea alveolaris may give rise to toxins which produce arthritic, alimentary, hemic, nervous, and other complications. Vaccines may be used to destroy the bacteria, and emetine-HCl to destroy the ameba. Emetine-HCl soln. loses amebicidal power on standing for several days, being decompd. by bacteria. Local application of emetine was found preferable to hypodermic administration; administration *per os*, as pellets, was least efficient. Local application of aq. soln. of neosalvarsan was effective in cases of pyorrhea, due primarily to spirochetes—probably to those of Vincent.

JOSEPH S. HEPBURN.

Influence of oil of chenopodium on circulation and respiration. W. SALANT AND A. E. LIVINGSTON. *Am. J. Physiol.* 38, 67-92(1915).—Intravenous injection of an emulsion of oil of chenopodium, 0.02 to 0.085 cc. per kg., caused in dogs, cats or rabbits (1) a fall of blood pressure, greater with dogs than with cats or rabbits, and of cardiac origin, (2) a diminished pulse, (3) a decrease of vagus irritability, (4) a depressed respiration both in amplitude and rate. Respiratory depression and apnea may be due to the liberation of O in the body from ascardiole, a peroxide. Apparently it is not due to a lowered sensitiveness of the respiratory center to CO₂. The fact that chenopodium has less depressant effect on respiration in the rabbit is due to the relatively larger amt. of CO₂ in the blood. No methemoglobin nor appreciable hemolysis was noted.

J. F. LYMAN.

Lime therapy of diabetes. MAX KAHN AND MORRIS H. KAHN. *Med. Record* 88, 744-6(1915).—Treatment with Ca salts reduced a daily minimum output of glucose of 90 g. to less than 10 g. The combination of Ca with various organs appears to influence the glucose production. In the case of the liver, Ca seems to act as an aid to glycogenesis, while the lack of Ca salts induces glycogenolysis. A further report is promised.

A. H. RAHE.

The effect of smoking on the circulation. JOHN AIKMAN. *N. Y. Med. J.* 102, 501-7(1915).—The subjects of these tests were men from 16 to 31 yrs. old. One Turkish cigarette of the better grade was consumed in each test. Sixteen out of 27 subjects showed an increase of 8 heart beats per min., 7 showed a smaller increase and 4 showed no effect. Two of the latter had abnormally high pulse rates at the start. In every instance the effect lasted for at least 15 min. after smoking ceased. Twenty-five tests were made of systolic pressure, there being a fall in 12 cases, an increase in 5, and no change in 8. The av. fall was 6.16 mm. and the gain 5.8 mm. If changes of less than 4 mm. be disregarded, 4 subjects showed an increase and 8 a decrease. Twenty-four observations on pulse pressure showed an av. fall of 8.16 mm.; 7 showed increased and 2 unchanged pressure. In 5 cases, in which the change in pulse pressure was marked, there was an increase in 2 instances and a fall in 3.

A. H. RAHE.

The recovery of *Entameba buccalis* in pyorrhea pus and treatment by emetine hydrochloride. ERNEST STURRIDGE. *Proc. Roy. Soc. Med., Odontological Section* 8, 501-3(1915). *Entameba buccalis* was found in 78% of the cases of pyorrhea examd. Emetine-HCl injected into the pus pockets killed this organism in every instance. Treatment with Zn ions proved equally effective. The weak point in the emetine treatment is its failure to kill organisms other than entameba. Cf. C. A. 9, 3300.

A. H. RAHE.

The relation of the fatal dose to the surface. KARL KISSKALT. Univ. Königsberg. *Biochem. Z.* 71, 469-77(1915); cf. Dreyer and Walker, C. A. 8, 2001, 3203, 356.—From expts. on rats and mice it is shown that Dreyer's statement, that the maximal dose can be calcd. from the body surface alone, is incorrect, and that other factors must be considered.

C. J. WEST.

Chemopathological studies with compounds of arsenic. I. Types of the arsenic kidney. LOUISE PEARCE AND WADE H. BROWN. Rockefeller Inst. *J. Exp. Med.* 22, 517-24(1915).—Arsenious acid, atoxyl, arsacetin, arsenophenylglycine, salvarsan, neosalvarsan and galyi were studied. In general, two types of kidney were produced in the treated animals, the red and the pale, with a variety of subdivisions of each type, depending upon the modifications in the chem. constitution of the compd. used, dosage, and length of survival of the animal. **II. Histological changes in arsenic kidneys.** *Ibid* 525-34. The type of renal lesion produced by As compds. varies widely. Some arsenicals produce changes in which vascular injury predominates; others produce an equally dominant tubular injury. Each compd. of As tested produces a lesion-complex in the kidney that is relatively characteristic for that compd. The mode and character of the action of arsenicals are dependent upon their chem. constitution. **III. The pathological action of arsenicals on the adrenals.** *Ibid* 535-43.—The following figures represent roughly the doses in g. per kg. body wt. causing death in guinea pigs in 1 to 3 days: Arsenious acid, 0.010-0.012; arsenic acid, 0.015-0.020; Na cacodylate, 0.700-1.000; atoxyl, 0.080-0.100; arsenophenylglycine, 0.250 or less; neosalvarsan, 0.300-0.350. Toxic doses of all known arsenicals produce definite pathological changes in the adrenals of guinea pigs. These changes include congestion, hemorrhage, disturbances in the lipid content, cellular degeneration and necroses and reduction of the chromaffin content. The character and severity of the injury varies with the chem. constitution of the compd. used. Adrenal injury may be an important factor in arsenical intoxication. Therapeutic doses of some arsenicals may produce adrenal stimulation. Cf. *C. A.* 9, 3296. C. J. WEST.

Further study of the bactericidal action of ethylhydrocuprein on pneumococci. HENRY F. MOORE. Rockefeller Inst. *J. Exp. Med.* 22, 551-67(1915); cf. *C. A.* 9, 2921.—The serum of rabbits which have been previously treated with a single dose of ethylhydrocuprein exerts a bactericidal action on, and later inhibits the growth of, pneumococci in the test-tube. These actions are most evident in the serum of rabbits when the base is given in oil subcutaneously; they are least evident, or absent, when the hydrochloride in H_2O is introduced directly into the stomach. In the case of the base given in oil subcutaneously to rabbits in dosage of 0.1 g. per kg. of body wt., the bactericidal action of the serum is at its max. about 1 hr. after administration, and it passes into an inhibitory effect about 4 hrs. after the drug has been given. In men the same inhibitory and bactericidal actions of the serum are present when a single dose of 0.5 g. of the hydrochloride is given by mouth or subcutaneously, but the bactericidal action is not so marked as in rabbits. When the concn. of the hydrochloride in the serum has diminished to a certain point in relation to the number of pneumococci present, the pneumococci which have survived the bactericidal action for a few hrs. acquire the power of growing freely. C. J. WEST.

Action of the lethal dose of strophanthin in normal animals and in animals infected with pneumonia. ROSS A. JAMIESON. Rockefeller Inst. *J. Exp. Med.* 22, 629-45(1915).—When a given amt. of strophanthin is injected intravenously, the mortality is the same in normal cats and in cats suffering with exptl. pneumonia. The minimum lethal dose of strophanthin is the same in normal dogs and in those with exptl. pneumonia. The presence of an acute infection does not interfere with the action of strophanthin on the heart. Electrocardiographically the changes occurring in the heart action when strophanthin is injected are found to be similar in normal and in infected animals. These facts renders it probable that a like similarity may be anticipated in man, under normal conditions and in pneumonia. C. J. WEST.

The toxic substance in cottonseed meal (WITHERS) 12.

I. ZOÖLOGY.

R. A. GORTNER.

The influence upon tadpoles of feeding desiccated thyroid gland in variable amounts and of variable iodine contents. C. H. LENHART. Western Reserve Univ. *J. Exp. Med.* 22, 739-46(1915).—The feeding of dried thyroid gland to tadpoles causes an early differentiation in proportion to the quantity fed or the % of I content of the gland used. With the larger doses and the higher I %, metabolism is stimulated to such an extent that the animals emaciate rapidly and die early, before there is time for much differentiation. With smaller amts. and lower I % the size of the animals is roughly inversely proportional to the amt. or %, so that a close association of differentiation with pigmy size is not characteristic of thyroid feeding as such, as Gudernatsch seems to conclude. One may see early and marked differentiation along with large size. Non-thyroid I does not have this effect. The thyroid effect is inhibited by exposure to cold and by cracker feeding. Exposure to cold probably acts by lowering metabolism, cracker feeding by substituting food other than the animal's own tissues to meet the increased demands caused by the stimulating effect of the thyroid feeding. The reaction of tadpoles to thyroid feeding is so sensitive that the procedure might well serve as a biological test for the activity of thyroid tissue, superior even to chemical methods.

12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

The development of food chemistry and pure food legislation in the German Empire. H. KUTTENKEULER. Elberfeld. *Naturwissenschaften* 3, 509-13(1915).—K. quotes the earliest laws passed in Germany and briefly reviews the present state control of foodstuff, quality, methods of production, storage, etc.

C. G. F.

A useful modification of the so-called Mohler reaction of benzoic acid. J. GROSSFELD. *Z. Nahr.-Genussm.* 30, 271-3(1915).—The use of hydroxylamine hydrochloride instead of $(\text{NH}_4)_2\text{S}$ for the reduction is recommended because the former has no color of its own to interfere with subsequent colorimetric comparisons. The method is based in other respects upon the modification of von der Heide and Jacob (cf. *C. A.* 4, 1523). The ether ext. is evapd. to dryness in a test tube, heated for 20 min. in a water bath with 0.1 g. KNO_3 and 1 cc. concd. H_2SO_4 , cooled and treated with 2 cc. H_2O . After cooling it is made alk. with 10 cc. of 15% NH_4OH and mixed with 2 cc. of a soln. of 2 g. hydroxylamine hydrochloride in 100 cc. water. In the presence of benzoic acid more or less of a red color appears according to the amt. present. Estn. may be made by comparison with the color developed by adding KCNS to a soln. of ferric alum (0.860 g. Fe alum in 1 l. of acidified H_2O).

L. D. ELLIOTT.

Report on vegetables. E. W. MAGRUDER. *J. Assoc. Official Agr. Chemists* 1, 199-200(1915).—For detg. the % of easily separable liquid in canned tomatoes the regular fertilizer sieve with 1 mm. round holes is very satisfactory. The tomatoes should stand on the sieve about 5 min., being gently stirred with a spatula when first poured on and at the end of the time. As a result of testing in this way 77 cans of tomatoes, M. considers that those which do not contain more than 50% of separable fluid are excellent.

H. S. BAILEY.

Report on water in foods. W. J. MCGEE. *J. Assoc. Official Agr. Chemists* 1, 218-21(1915).— H_2SO_4 , CaCl_2 , Na, CaCl_2 , P_2O_5 , BaO_3 , and glycerol as drying agents at room temp., under both 76 mm. and atm. pressure, were tested. The foods dried were cheese, cocoa, corn meal, and raw sugar. A study of the tabulated results shows that

H_2SO_4 , P_2O_5 , CaC_2 and metallic Na are about equal in dehydrating power. Probably CaC_2 and Na are the most practical reagents. Dehydration in a partial vacuum is not always more nearly perfect than over the same medium at atm. pressure. In a desiccator at room temp. under 760 mm. in 48 hrs. the materials used for tests lost 80 to 96% of their total H_2O , and at 75 to 100 mm. they lost as much in 24 hrs. The detn. of H_2O by the vacuum method over H_2SO_4 is recommended as an optional official method.

H. S. BAILEY.

The estimation of starch in cocoa by means of taká-diastase. CECIL REVIS AND H. R. BURNETT. *Analyst* 40, 429-32(1915).—Weigh 5 g. fat-free dry cocoa matter into a beaker, thoroughly stir with 50 cc. of 10% (by vol.) alc., and filter under pressure, preferably on a Büchner funnel. Wash with two 50 cc. portions of 10% alc., and then with 10 cc. of 95% (by vol.) alc., taking care that the cocoa sucks dry at no stage. Scrape and wash the moist cocoa into a 250 cc. flask with 125 cc. of boiling water. Mix well, and place in a boiling water bath with const. shaking for 15 min. to gelatinize the starch. Cool to 38°, mix with 0.05 g. taká-diastase rubbed in a little water, add 2 cc. toluene, and after shaking and stoppering place in an incubator at 38° for 24-36 hrs., shaking at intervals. Then add 10 cc. 0.1 N NaOH to stop the action. Cool to 15°, add about 100 cc. water, run in 10 cc. acid mercuric nitrate soln. (pure HgO dissolved in twice its wt. HNO_3 (d. 1.42) and the soln. dild. to 5 times its vol. with water) on the surface, and finally add water to the mark below the toluene. Mix well and filter. Carefully measure 100 cc. of the filtrate into a flask, add 0.5 g. $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$, and after this has dissolved run in 10 cc. NaOH soln. with agitation. Ten cc. of the NaOH soln. should just neutralize 4 cc. of the mercuric nitrate soln., and on no account should there be an excess of alkali. A slight acidity is preferable. Mix and filter the contents of the flask, and use 50 cc. of the filtrate for a grav. Cu detn. The polarimetric readings are also made on this filtrate. Examns. of cocoa shell by this method gave only negligible reductions, showing that no true starch is present, and confirming microscopic results. Detns. by the acid conversion or diastase methods invariably indicate considerable amts. of starch.

P. B. DUNBAR.

Report on cocoa and cocoa products. H. C. LYTHERG. *J. Assoc. Official Agr. Chemists* 1, 200-2(1915).—The present (1913) methods of the A. O. A. C. for the detn. of milk fat and lactose are satisfactory. The Baier and Neumann method (*C. A.* 4, 353) for casein is recommended for provisional adoption.

H. S. BAILEY.

The tea of Tchakva near Batoum (Caucasus). P. G. MÉLIKOV AND M. ROSENBLATT. *Russ. J. Exp. Landw.* 16, 213-6(1915).—The mild and humid climate of Batoum as well as the soil (laterite) are completely favorable to the culture of tea (*Thea chinensis* L.). The processes of harvesting, desiccation, and fermentation recall those used in India. In its content of theine, tanning substances, total N, organic and mineral matter sol. and insol. in water, and matter sol. in ether, this tea resembles the teas of China and India. The soil of Tchakva is rich in Mn and the ash of the tea of this region is also remarkable for its considerable content of this metal.

W. H. F.

Some effects of storage on coffee. R. E. DOOLITTLE AND BURNETT B. WRIGHT. *Am. J. Pharm.* 87, 524-6(1915).—An investigation of the effect of storage on the gain or loss in wt. of freshly roasted coffee, prepd., transported and stored under ordinary commercial conditions. The results showed that there was an increase over the original wt. in all samples and at all weighings during the 60 weeks covered by this expt.

W. G. GAESSLER.

Caffeine determinations in coffee. G. FENDLER AND W. STÜBER. *Z. Nahr.-Genussm.* 30, 274-6(1915).—Supplementing their previous work (*C. A.* 8, 3599), F. and S. have tried the Burmann method (*C. A.* 4, 1777) for the detn. of caffeine in coffee. Operating upon a coffee containing 1.34% caffeine as described by B. only 0.45 to

0.79% was recovered. It was found that the process of subliming the caffeine quant. is incomplete at the end of 3 hrs. but that better yields are obtained if the sublimation is continued for 12 hrs. Even then too little caffeine is recovered and the results are too variable (0.93 to 1.25%), the method being pronounced inaccurate for these reasons.

A. F. SEEKER.

Report on tea and coffee. J. M. BARTLETT. *J. Assoc. Official Agr. Chemists* 1, 203-8(1915).—The methods proposed by Gorter, and Fuller, and a modification of Stahlschmidt's method, for the detn. of caffeine were tried out on a sample of coffee and of tea by 4 collaborators. The details of these methods and various modifications, and comments on them, are given. Results by all 3 methods are quite satisfactory on coffee, but those by the Fuller method were low on tea. This method yields a fairly pure caffeine, but the extns. are tedious and incomplete. In the Gorter method the caffeine is impure, so that it is necessary to det. the N in the residue to get correct results. Further work on all the methods is recommended before any is adopted.

H. S. BAILEY.

Report on vinegar. E. H. GOODNOW. *J. Assoc. Official Agr. Chemists* 1, 496-8 (1915).—Collaborative work on methods 6, 11, 15, 16, and 17 (solids, ash, fixed acid, volatile acid, and Pb ppt., resp.) *Bur. Chem. Bull.* 152 (1911) showed that these are accurate and reliable and should be adopted as provisional.

H. R. SMITH.

Report on food adulteration. J. HORTVET. *J. Assoc. Official Agr. Chemists* 1, 465-70(1915).—A summary of the reports for 1914.

H. R. SMITH.

A bacteriological study of retail ice cream. S. H. AYERS AND WILLIAM T. JOHNSON. U. S. Dept. Agr., *Bull.* 303, 24 pp.(1915); cf. *C. A.* 9, 1810.—A study of the number of bacteria in commercial ice cream as purchased from retail stores in Washington, D. C., during the summer and winter seasons showed a wide range in the bacterial content, and that the av. number of bacteria in ice cream from each manufacturer is distinctly lower during the winter months: The summer av. of 94 samples was 37,859,907 per cc. with a max. of 510,000,000 and min. of 120,000, while the winter av. of 91 samples was 10,388,222 with a max. of 114,000,000 and min. of 13,000 per cc. The bacterial groups bore much the same relation to each other in the av. summer and winter samples; however, in the summer samples, a higher % of the acid-coagulating group of bacteria and a lower % of the alkali and peptonizing groups than in the winter group was noted. Gas-forming bacteria of the colon-aerogenes group detd. on litmus-lactose-asparagine agar were found in 0.1 cc. in 88.33% of 120 samples examd., the greatest number being in the summer samples. Methods of examn. and tables classifying the bacteria found are given.

E. H. INGERSOLL.

Rapid method for determining water and fat in butter and margarine. A. A. BESSON. *Basel. Chem. Ztg.* 39, 770-2(1915).—The fat detn. is carried out in Huggenberg and Stadlinger's "Sapometer" (*C. A.* 6, 2341) as follows: Weigh 5 g. substance into a beaker, add about 40 cc. HCl (2:1), boil a few mins., cool (but not till the fat solidifies), wash carefully into the sapometer, add about 100 cc. Et₂O and enough H₂O (or Et₂O) to bring the Et₂O layer into the graduated portion of the app., shake well, let stand 15 mins., read the volume of the Et₂O soln., draw an aliquot portion into a weighed flask, evap. the Et₂O, then heat 30 mins. in a steam oven and weigh. The H₂O is detd. in an app. consisting of 2 Al dishes, the outer about 8 cm. diam. and 2.5 cm. high, the inner 6 cm. diam. and 1.5 cm. high. A cross lying on the inner dish supports an inverted Al funnel of about 2 mm. less diam. than the outer dish, and stem 1 cm. long, loosely closed with a wad. The app. is weighed, then about 5 g. substance weighed into the inner dish and the whole heated in an air bath so that 150-160° is reached in 15-20 mins. Cool the app. by standing in H₂O and weigh after about 10 mins. Cf. *C. A.* 1, 70; 3, 1098; 8, 1624; 9, 670.

J. H. MOORE.

Report on dairy products. J. HORTVET. *J. Assoc. Official Agr. Chemists* 1, 186-94(1915).—Samples of pure, sweet cream, the same cream homogenized with oleo oil (20%), and ice cream made from the same cream, with added gelatin, sugar and cottonseed oil, were submitted to 5 collaborators for analysis. The % of fat present was detd. by the Roese-Gottlieb and the continuous extn. method of Paul. The results indicate that the extn. method may be relied upon when carried out under proper conditions and by an experienced analyst. The results for fat by the extn. method will be higher than those obtained by the R.-G. method. It is recommended that the extn. method be adopted by the A. O. A. C. provisionally. Analytical results and details of the methods are given. H. S. BAILEY.

The effect of feeding on the composition of milk and butter, linseed cake and hempseed cake. H. T. CRANFIELD AND MARGARET G. D. TAYLOR. *Analyst* 40, 433-9(1915).—The compn. and quality of milk and butter produced by feeding hempseed cake is quite equal to that obtained by feeding linseed cake. The effect of removing cows from poor pasture to a well balanced ration in stall is shown by a large fall in % of fat and considerable rise in R.-M., Kirschner, and Polenske values, and a fall in the refractometer figure. P. B. DUNBAR.

The relation between the Reichert-Meissl, Kirschner and Polenske values for butter. H. T. CRANFIELD. *Analyst* 40, 439-42(1915).—The R.-M., Kirschner and Polenske values of 31 samples of butter (cf. preceding abstr.) are compared.

Kirschner value.	Average Polenske value.	Limits of Polenske value.
19-20	1.46	1.4-1.7
20-21	1.65	1.4-2.2
21-22	2.05	1.7-2.7
22-23	2.43	1.8-2.9
23-24	2.41	2.2-2.6

The ratios R. M.-K./P. varied from 1.97 to 2.98, but the majority of the samples lay between 2.2 and 2.8. P. B. DUNBAR.

Report on fats and oils. R. H. KERR. *J. Assoc. Official Agr. Chemists* 1, 181-6(1915).—With the assistance of 6 collaborators, the referee studied further the glycerol-KOH method for the prepn. of titer acids. On cottonseed oil the av. titer obtained by the proposed and the official method agreed to within 0.1°, on inedible grease within 0.01°, and on oleostearin were identical. The Emery method for the detection of beef fat in lard was submitted to 7 collaborators, each of whom worked on 8 samples of pure and adulterated lards. Their reports on the purity of these agreed very closely. It is recommended that the glycerol-KOH saponification method be adopted as official, and the Emery method as provisional by the A. O. A. C. H. S. BAILEY.

Report on fats and oils. R. H. KERR. *J. Assoc. Official Agr. Chemists* 1, 513-5(1915).—A study of 2 methods for the detection of phytosterol in mixts. of animal and vegetable fats: (1) Bureau of Animal Industry method (U. S. D. A. Bur. Animal Ind., *Circ.* 212) and (2) the digitonin method of Marcusson and Schilling (*C. A.* 8, 1022). Three samples were sent out: (1) Lard containing 5% cottonseed oil and 0.25% vaseline. This amount of vaseline would effectually prevent accurate observations by the present provisional method. (2) Pure lard, rancid. Rancidity interferes decidedly with the present method. (3) Lard containing 2.5% hydrogenated cottonseed oil and 2.5% soy bean oil. Three collaborators were led to correct conclusions by each method. The digitonin method is more simple and convenient but the reagent is expensive and difficult to obtain. The Bur. Animal Industry method requires more time and labor in manipulation but does not depend on an expensive reagent. Both

methods are decidedly superior to the present provisional method and are recommended for adoption by the association as provisional methods. H. R. SMITH.

Various methods for the determination of phytosterol by means of digitonin and a proposed new apparatus for this purpose. H. WAGNER. Duisberg. *Z. Nahr.-Genussm.* 30, 265-7(1915).—W. reviews the various methods proposed for this detn. The Marcusson and Schilling method (*C. A.* 8, 1022) is defective in that it does not ppt. the phytosterol existing as esters. The Klostermann method (*C. A.* 8, 536) appears to possess no special value, while that of Fritzsche (*C. A.* 8, 1315) also fails to ppt. the phytosterol esters and yields a product contaminated with digitonin. The Klostermann and Opitz procedure (*C. A.* 8, 3246) is too complicated though the results are good. Kühn and Wewerinke have proposed a method (*C. A.* 9, 1079) further modified by Kühn, Bengen and Wewerinke (*C. A.* 9, 2270) which W. considers to be the best of the procedures mentioned. W. employs a special app. for this detn.; it consists essentially of a short filtering tube into which a perforated porcelain plate can be fitted, the latter being covered, first with a paper disk, and then with a layer (5 to 7 mm. thick) of granulated pumice (0.5-1.0 mm. in diam.). The filter tube is fitted, by means of a rubber stopper, with a glass cup which surrounds the tube at the level of the porcelain plate and which is filled with warm water to prevent solidification of the fatty acids during filtration. When operating by the Klostermann method (*loc. cit.*) this app. is supplemented by a cylindrical separatory funnel fitted a short distance above the stem with a side outlet and stopcock. The digitonide may be pptd. in this funnel, the ppt. allowed to settle, and the clear liquid drawn off from the side outlet. The ppt. may be washed in the same way. The separatory funnel is then connected to the filtering tube described above by means of a ground glass joint, after which the stopcock at the stem of the separatory funnel is opened and the ppt. washed into the filtering tube by means of CHCl_3 or ether. After thorough washing of the ppt. the filtering tube may be disconnected from the separatory funnel, the water jacket, and the suction flask, dried at 105° in an oven, cooled and weighed. When operating by the K., B. and W. method the separatory funnel is not required. Illustrations are given. A. F. SEEKER.

Investigations on fatty fruits and seeds of our (German) colonies. V. Coula edulis and Limonia warneckei. H. WAGNER AND J. B. LAMPART. *Z. Nahr.-Genussm.* 30, 221-6(1915); cf. *C. A.* 9, 1811.—(1) *Coula edulis*. Nuts received from Kamerun are described and their dimensions given. The sound nuts yielded 30.48% fat, which was liquid at room temp., brown in color and had no especial odor or taste. Constants were detd. on the fat and fatty acids. (2) *Limonia warneckei*. The dimensions and description of some seeds obtained from Lome (Togo) are given. The amt. of fat extd. was 38.50%. Constants were detd. and other tests made on this fat. L. D. ELLIOTT.

Report on meat and fish. W. B. SMITH. *J. Assoc. Official Agr. Chemists* 1, 170-81(1915).—Methods for the detn. of starch in meat products proposed by Price and by Mayrhofer-Sachsse were studied. Although both depend upon the same principle, the Price method is the more simple, rapid and accurate. For the detn. of NH_3 nitrogen, the EtOH vapor method, the Folin-Pennington, and new Folin methods, were investigated. "Since the latest modification of the Folin method makes it as easy of operation as the EtOH method, it seems the best possible." For the detn. of sugar in meats, the provisional A. O. A. C. method (*Bur. Chem. Bull.* 107, Rev., p. 111), as given, and with the further addition of phosphotungstic acid, and a 3rd method based upon that of C. A. Browne (*Handbook of Sugar Analysis*), using $\text{Hg}(\text{NO}_3)_2$, followed by treatment with phosphotungstic acid were studied. The details of all methods are given. It is recommended that the Price method be made official for

starch, that the new Folin method (*C. A.* 7, 2643) be adopted for NH_3N , and that further study be made on the Hg phosphotungstic acid method for clarifying meat sugar solns., with reduction according to Munson-Walker or Bertrand. H. S. B.

Report on cereal products. H. L. WHITE. *J. Assoc. Official Agr. Chemists* 1, 195-9(1915).—The method of Bryan, Given and Straughn (*Bur. Chem., Circ.* 71) for sol. carbohydrates was tried out with 2 samples of flour. The results obtained warrant its adoption as an official method of the A. O. A. C. The official method, a vacuum desiccator, and a vacuum oven method for the detn. of H_2O in flour were investigated by 2 collaborators (details of results and methods are given). Apparently 5 or 6 days in a vacuum desiccator gives the max. loss of wt. Detns. of gluten in 2 flours were made by the Olsen method, and that given in *Bur. Chem. Bull.* 122, p. 54. Results on the detn. of the acidity of the water ext. of flours by extg. at 40° indicate that it is desirable to limit the extn. to 2 hrs., and that perhaps 1 hr. will be more satisfactory.

H. S. BAILEY.

Judging cereal flours. A. HEIDUSCHKA AND K. HEINICH. *Z. Nahr.-Genussm.* 30, 226-8(1915).—Because of war regulations in Germany resulting in the grinding of a greater proportion of the bran into the flour, interest in detg. bran content has been aroused. Work previously done on bran residue by Raumstedt (*C. A.* 9, 2952) was incomplete due to the lack of numerical data. H. and H. have devised a method which is both rapid and accurate. Grind 2.5 g. of meal very fine with 10 cc. H_2O , add 20 cc. concd. HCl (d. 1.19), mix thoroughly and allow to stand covered $\frac{1}{2}$ hr. at room temp. Centrifuge the mixt. about 10 min. (centrifuge 2000-3000 r. p. m.), decant, and filter the residue through an 11 cm. weighed filter. Wash the residue on the paper once with dil. HCl (25%), and twice with water, using 10 cc. in each washing, and dry to const. wt. By this method it is possible to get all the hydrolyzable substances of the meal into soln. and the insol. residue in a form possible to weigh. It is then possible to make a further microscopical analysis of the bran. This method can be used in conjunction with the starch detn. of C. J. Lintner (*C. A.* 2, 553). Tables are given showing % H_2O and bran residue in rye, wheat and white flour meals.

HELEN N. ELLIOTT.

Gossypol, the toxic substance in cottonseed meal. W. A. WITHERS AND F. E. CARRUTH. N. C. Agr. Exp. Sta. *J. Agr. Research* 5, 261-88(1915); cf. *C. A.* 9, 1516.—Cottonseed kernels, previously extd. with gasoline, were treated with ethyl ether. Evapn. of the ether leaves a crude product designated "gossypol extract." A purer product, "precipitated gossypol," was obtained from the ethereal soln. by the addition of gasoline, and a cryst. product, "gossypol acetate," by pptn. by acetic acid. Gossypol was fatal to rabbits when administered intraperitoneally in the form of gossypol ext. or cryst. gossypol acetate, either when fed in one large dose in the form of gossypol ext. or when fed in small daily doses in the form of gossypol ext., pptd. gossypol, or gossypol "acetate." The smallest amt. of gossypol administered intraperitoneally and found fatal to rabbits was 0.24 g. of cryst. gossypol acetate per kg. of live wt. Gossypol forms an oxidation product which is non-toxic. Cottonseed kernels are rendered less toxic by the partial extn. of gossypol and non-toxic by a more nearly complete extn. of it. Methods for rendering cottonseed kernels non-toxic depend upon extg. the gossypol or changing it to physiologically inert forms by oxidation or by pptn. A bibliography is appended.

W. H. FRY.

The question of the quantitative determination of potato addition to bread, and the determination of the milling grade of the flour used for bread-making. J. ABEL. *Z. Nahr.-Genussm.* 30, 129-138(1915).—A. finds that the ash of wheat and rye flour is high in mineral acids (phosphates) and low in bases while that of potato flour is high in bases and low in acids. The alkalinity of the various ashes was calcd. by adding

the mg. of each base figured as oxide in 1 g. of flour or bread and subtracting from the total the acid value figured as the total mg. of P_2O_5 , SO_3 and Cl in 1 g. of bread or flour. (CO_2 and SiO_2 were not counted.) In the case of rye and wheat this number is negative; in potato it is positive. The analytical procedure is as follows: Rub up 20 g. of the dried and pulverized bread (or flour) with ten cc. 0.5 N Na_2CO_3 , adding a little water to make a paste, if necessary. Transfer this to a Pt dish with the aid of a glass rod, which is cleaned with a piece of ashless filter paper. After drying gradually burn over a piece of asbestos which is arranged so as to prevent the flame from coming in contact with the charred material. Leach with a little hot water and ash again until no more gas is given off; evap. the aq. ext. and return to Pt dish. Dry at $110-120^\circ$ and heat until the dish is at low red heat. Transfer the weighed ash to a small Erlenmeyer flask with 30 to 40 cc. boiled water, and det. the CO_2 by the Fresenius-Classsen method. For driving out the CO_2 use 10 cc. of N HNO_3 . After expelling the CO_2 transfer the ash soln. with as little boiled water as possible to a 100 cc. glass-stoppered cylinder, add 5 cc. of exactly neutral $Ca(NO_3)_2 \cdot NH_4NO_3$ soln. (5 g. $Ca(NO_3)_2$ and 10 g. NH_4NO_3 in 100 cc. H_2O) and 20 cc. 0.5 N NH_4OH , make up to 100 cc., shake hard, and let stand for 24 hrs. Pipet 50 cc. of the clear supernatant liquor and neutralize with 0.1 N HNO_3 , using methyl orange as indicator. Then titrate the neutralized soln. for Cl with 0.1 N $AgNO_3$ against K_2CrO_4 (with bread dil. to 250 cc., with flour direct). In calcg. the alkalinity of the ash the N HNO_3 and 0.5 N NH_4OH used are disregarded as they exactly neutralize each other. The 10 cc. 0.5 N Na_2CO_3 used equals 50 cc. of 0.1 N Na_2CO_3 and the 0.1 N HNO_3 (x) used for back titration gives the alkalinity, $-50 + 2x/10$. This is only positive when $x = 25$. Since 1-2% NaCl is added in bread making, a correction for that is made by subtracting from the total ash the amt. of NaCl found by the Cl detn. Also 10 cc. 0.5 N Na_2CO_3 was added at the start and the corresponding quantity of Na_2O (0.155 g.) and CO_2 (0.110 g.) must be subtracted in order to get the net ash. Correction should also be made for the ash of the yeast soln. used. Figures are given for various breads and flours to prove the feasibility of detg. the addition of potato flour. This may be made quant. if the ash analysis of the original wt. of rye flour used is known. The milling grade of flour used in bread making can be judged if the ash of the flour is known. Increases in the ash would indicate the various grades.

H. L. LOURIE.

New methods of preparing conserved foods. W. SCHEFFER. *Z. Nahr.-Genussm.* 30, 261-5 (1915).—A review on the American "puffed" rice and wheat, with a study of their physical and microscopical properties.

HELEN N. ELLIOTT.

Quantitative determination of the amino acids of feeding stuffs by the Van Slyke method. II. H. S. GRINDLEY AND M. E. SLATER with H. C. ECKSTEIN AND J. C. ROSS. *J. Am. Chem. Soc.* 37, 2762-9 (1915); cf. *C. A.* 9, 2407.—In addition to the values previously given for cottonseed meal, tankage and alfalfa hay, the following are now reported for blood meal, wheat, rolled wheat, barley, oats and white soy beans, resp. (expressed in % of the total N): Ammonia N, 5.85, 17.59, 17.04, 15.16, 13.06, 10.12; humin N, 3.95, 9.21, 9.04, 8.79, 9.94, 6.63; arginine N, 9.16, 7.99, 8.20, 9.46, 11.42, 12.67; cystine N, 0.69, 1.34, 1.66, 1.26, 1.16, 0.67; histidine N, 8.53, 1.67, 3.21, 3.64, 4.32, 5.77; lysine N, 9.73, 2.47, 2.48, 2.19, 3.49, 6.14; amino N in filtrate from bases, 56.57, 47.67, 47.70, 45.81, 51.72, 49.79; non-amino N in filtrate from bases, 4.42, 13.59, 13.93, 13.84, 7.90, 8.56. The results are also given in % of the feeding stuffs. The results confirm the earlier conclusion that the V. S. method for the detn. of the chem. groups characteristic of the amino acids of proteins can be applied directly to feeding stuffs with at least a fair degree of accuracy. The values found, however, do not agree well, on the whole, with Nollau's (*C. A.* 9, 2780); this is probably due in the main to differences in the details of exptl. procedure. There are pronounced variations in

the free and combined amino acid content of the common feeding stuffs, expressed in % of the total N or of the feeding stuff. The high results for humin N are due, in part, to the presence of sol. carbohydrates during the hydrolysis of the proteins and probably in part to the presence of cellulose which mechanically prevents complete hydrolysis; these high results constitute a source of error in the direct application of the V. S. method.

CHAS. A. ROULLIER.

The utilization of bones for food. G. MORPURGO. *Oesterr. Chem. Ztg.* 18, 139 (1915).—A nitrogenous food can be prepd. from bones in a manner similar to the prepn. of glue. Bones, which have been boiled, are better suited than fresh ones. The ground material is treated with dil. HCl. The insol. matter, containing the valuable nutritive constituents, is treated with dil. NaHCO₃ soln. to ppt. the remaining Ca salts. The resulting product is concd. and added to soups.

ARTHUR LEDERER.

Proso and kaoliang as table foods. N. E. HANSEN. South Dakota Agr. Expt. Sta., *Bull.* 158, 147-76(1915).—Analysis of the unhulled seed of white Siberian proso introduced from Siberia by H. gave crude protein 13.12, ether ext. 2.10, fiber 8.30, ash 3.51, moisture 9.90%. This variety of millet is very drought resistant. Results of milling and eating tests are given, as well as a number of recipes for bread, cakes, etc., in which proso is one of the ingredients. Analysis of a flour made from kaoliang using a no. 100 screen analyzed as follows: fat 2.09, crude fiber 0.65, crude protein 7.81%. As the coarsely ground kaoliang runs 14.93% it is evident that this screen takes out too much protein. Recipes are given in which kaoliang is substituted for Kafir flour.

Use of blood as human food and the behavior of formaldehyde in the organism (SALKOWSKI) 11A. Occurrence of manganese in wheat (HEADEN) 11D. Color reactions of furfural and hydroxymethylfurfural (SCHENK) 17.

Economizing yeast in bread-making. H. A. KOHMAN, C. HOFFMAN and A. E. BLAKE. U. S., 1,158,933, Nov. 2. About 0.06% of NH₄Cl and 0.12% of CaSO₄ is

added to the dough. This addition either decreases the necessary time of fermentation if the usual amt. of yeast is used or permits the use of less than the usual amt. of yeast if the usual time of fermentation is allowed. Cf. *C. A.* 9, 2784.

Accelerating fermentation or saving yeast in bread-making. H. A. KOHMAN, C. HOFFMAN AND A. E. BLAKE. U. S., 1,158,934, Nov. 2. About 0.12% of CaSO_4 is added to the dough which promotes the growth of the yeast.

Desiccated milk. E. F. W. WIEDA. U. S., 1,159,455, Nov. 9. A dried milk powder each of the fat-containing particles of which is enclosed by a layer of sugar and gelatin is formed by mixing milk and cream with sugar and gelatin in a finely divided or homogenized condition, and then drying the mixt. The product may be used in making ice cream.

Smooth creamy bacterial milk product. C. F. C. KNUDSEN. U. S., 1,160,086, Nov. 9. Sweet skim-milk is coagulated by the action of about 2% of combined cultures of *B. bulgaricus* and *B. lactic-acidi*, heated to 35° for 14-18 hrs. and washed free from whey. The residue is an amorphous product containing protein and milk sugar and about 0.2% butter fat. It somewhat resembles cottage cheese but is free from acid and of low cohesion and better keeping quality than cottage cheese. It has a mild nutty flavor, smooth creamy consistency and cream color.

Cheese. J. W. SPENCER and F. P. SCHWINGEL. U. S., 1,159,808, Nov. 9. Coagulated milk is forced from the coagulating tank under air pressure into a moisture-expressing compartment and the air pressure is utilized also to express the whey from the coagulated milk.

Shredded wheat biscuits. J. L. KELLOGG. U. S., 1,159,045, Nov. 2. Crushed wheat is cooked with steam in a retort under 15 lbs. pressure per sq. in. The material is allowed to dry in the air for 24 hrs. after cooking, granulated and further dried by a current of air, treated by shredding rollers, baked in covered pans at a temp. of 205-260° and dried, after removal from the pans, at 120-150°.

Puffed flake cereals. F. B. MARTIN. U. S., 1,161,323, Nov. 23. Flaked cereal, e. g., corn, containing moisture is slowly dried at a low temp., preferably about 22°, to form a tough film on the flakes and then quickly heated to a considerably higher temp. to puff them by expansion of steam within the flakes.

Food. N. SULZBERGER. U. S., 1,160,783, Nov. 16. A mixt. of flour dough with peptonized vegetable albumin is baked to form crackers.

Laxative cracker. W. L. BREYFOGLE. U. S., 1,161,450, Nov. 23. Exhausted sugar beet pulp, 15, wheat flour 60, lard 10, honey 13, salt 1, NaHCO_3 0.5 and phenolphthalein 0.5 part is used in making crackers.

Soluble coffee extract. G. H. BENJAMIN. U. S., 1,158,431, Nov. 2. Green coffee beans are allowed to stand in warm H_2O for 12-24 hrs. to effect partial germination and production of maltose. Then they are heated to about 55° and treated with warm air to remove moisture, roasted, ground and extd. with H_2O at 55-65° and the ext. is concd. and dried with dehydrated air. Alc. and ether may be used for extg. the beans instead of H_2O .

Cooking pulse or similar foods. E. J. VAUDREUIL. U. S., 1,159,136, Nov. 2. A series of measured batches of the material are successively passed through a cooking app. and then scoured and strained to sep. the liquid.

Bread. G. F. HUMPHREY. Brit., 17,750, July 27, 1914. Mfg. bread or the like with little or no yeast or its equiv., by placing the dough in an oven heated initially

to about 180° F., reducing the pressure to between 10 and 20 in. of Hg, raising the temp. gradually to about 230° F., and, after the dough has risen sufficiently, allowing the pressure to rise to that of the atm. The bread, during baking, may be subjected to the action of elec. incandescent lamps or the like, and wet or satd. steam may be introduced to maintain the elasticity of the crust during the rising stage, and be followed by dry or superheated steam to harden the crust. The oven may be initially heated from the bottom alone and subsequently from the top alone.

Malt compositions. B. COMBE. Brit., 17,113, July 20, 1914. In making a food consisting of milk or cream, honey, barley malt, and, if desired, wheat flour, elec. currents are passed through the materials during the mixing. The currents may be passed between C grills in the mixing vessel.

Electrolytic treatment of grain, seeds, and flour. C. W. CHITTY, W. JAGO and W. WATSON. Brit., 16,664, July 13, 1914. Obtaining food products and flour-improving compns. by electrolyzing a mixt. of H₂O and wheat or other cereal, peas, beans, or other pulse, or their products such as middlings, bran, germ, or offals. The H₂O may be rendered conductive by adding H₂PO₄ or the acid or alk. product from a previous operation. A mixt. of the cereal substance and H₂O may be treated in a simple elec. cell, and the liquid, after or without the removal of the exhausted cereal substance, evapd. to dryness or otherwise treated to remove H₂O, the residue forming a flour improver. Or a glass cylinder may be employed, having at the bottom a Sn cathode, and at the top a Pt anode. Some of the alk. liquid produced at the bottom is drawn off, and the remaining liquor is strained from the solid residue, may be re-electrolyzed, and is then employed for treating flour. If an electrolytic cell having a porous partition be employed, wheat placed in the anode compartment will absorb the products of electrolysis and is then dried, ground, and added to flour. Or a mixt. of bran and H₂O in the cathode compartment, with H₂O in the anode compartment may be electrolyzed, and the liquor strained from the solid added to the product in the anode compartment and re-electrolyzed, being placed in the anode compartment of a cell having a porous partition, with H₂O in the cathode compartment. The product in the anode compartment is used for treating flour. With a cell having 2 porous pots into which the electrodes project, the pots are filled with H₂O and surrounded by a mixt. of cereals or their products and H₂O. The acid ext. produced in the anode pot is used for treating flour, and the liquid in the cathode pot and exterior part of the cell may contain food products. The liquid product may be concd. to form a food product to be employed directly or in combination with other substances. The grain used may be malted or germinated before use. A cathode of Al may be employed.

A sour milk preparation. W. KUNTZE. Ger., 285,211, Jan. 28, 1914. Heated sterilized milk is mixed, with or without evapn., after cooling to 45-55°, and with stirring, with previously dissolved pure citric acid (0.5-1 g. to 1 liter or equiv. amt. of lactic acid), and then inoculated with pure cultures of *Diplostreptococcus bulgaricus* in solid or liquid form in predetd. amts. From 1 to 2% of the liquid pure culture is taken. After the first inoculating material has distributed itself sufficiently, 1% of a pure liquid culture of *B. bulgaricus* is added, the acid-forming power of which has been weakened, for the time, by heating to about 60°, or for a shorter period to higher temps. The milk which has been thus pretreated and inoculated is hermetically sealed in sep. portions and is kept at 40-50° until coagulation has been effected. If pasteurized milk is inoculated with such cultures, the milk prepd. in this manner, does not sour further upon pr.

Mechanical analyses of sands. PHILIP BURGESS. *J. Am. Water Works Assoc.* 4, 493-514(1915); *Can. Eng.* 29, 496-8(1915).

LANGDON PEARSE.

Development of ultraviolet water disinfection. ANON. *Eng. News* 74, 634-6 (1915).—The 320 plants installed or approaching completion in the U. S. comprize 20 for swimming pools. The cost is about \$750 per 1000 gal. per hr. capacity for machines of 200 to 3000 gal. per hr. and \$900 for those of 60 to 120 gal. per hr. capacity. Direct current is used at 110 to 500 v. For swimming tanks, a pressure filter is used followed by sterilization.

LANGDON PEARSE.

Treatment of water with hypochlorite. JOSEPH RACE. *J. Soc. Chem. Ind.* 34, 931-4(1915); *Can. Eng.* 29, 613-6(1915).—Thorough mixing aids efficiency. Velocity of reaction is lowered by reduction of temp. Color and turbidity increase the amt. of Cl required. At Ottawa use of $CaOCl_2$ reduced typhoid death rate from 85 (2 years preceding) to 21 and 13 per 100,000 (2 years following). R. recommends concrete tanks painted with asphaltum, galvanized Fe pipes of generous size, cast Al stirring vanes on bronze shafts and hard bronze or vulcanite valves. The cold water was odorless, but on heating it sometimes acquired a fish-like odor. Treated water had no effect on animals or plants. Corrosion in hot water systems was traced to CO_2 .

LANGDON PEARSE.

Saving by water softening. ANON. *Practical Engineer* 19, 766(1915).—In-crusting solids are reduced from 28 grains per gal. to about 0.5, greatly increasing the efficiency of the boilers. Comparative costs and savings are given. W. H. B.

Softening plant for converting hard, impure river water into boiler feed supply. J. C. W. GERRA. *Eng. Record* 72, 622-4(1915).—The water from the Mahoning River is treated at Youngstown, Pa., with lime and soda ash. The plant consists of steel reaction and settling tanks, 30 ft. in diam. and 26 ft. high, each holding 120,000 gal. Each tank is equipped with mechanical stirring devices, 3 centrifugal pumps for reagent—
for
at:
ical gravity filters of steel, each 15 ft. in diam. with a capacity
Automatic scales are used in measuring the chemicals. Med-
ided crushed quartz supported by a layer of gravel are used.
* no permanent hardness and the Ca and Mg salts are re-
ilities in distd. H_2O . The mechanical features of the plant

FRANK BACHMANN.

Method of softening and purifying feed-water. ANON. *Elec. World* 66, 413 (1915).—The app. consists of 3 tanks with filling and inside arrangements similar to those of a sand filter but with a layer of special porous mineral substance (permutite). One tank contains Mn permutite and 2 contain Na permutite. The feed H_2O passes into the tank containing Mn where Fe is removed by oxidation and deposited as a sludge, and into one of the other tanks where Ca and Mg are removed. The Ca and Mg remover consists of a perforated tray containing gravel or crushed marble, below which is an open space, then a layer of Na permutite resting on a bed of gravel which is supported on another perforated platform. A pipe connecting with the upper part of the tank delivers the raw water on the gravel where acid is removed and the water distributed over the permutite. Regeneration of the material is necessary. Both kinds of tanks have to be regenerated, the Mn by back washing and satn. with 2% $KMnO_4$ and the Na by back-washing and subsequent treatment with 10% NaCl. These tanks are duplicates and are used alternately as regeneration requires about 10 hrs. Analysis shows the efficiency of this app. W. H. BOYNTON.

The value of mechanical filters in the purification of water. MARTIN DEACON, S. RIDEAL, F. PULLEN CANDY AND OTHERS. *Surveyor* 47, 742-4 (1915).—Discussion of paper by OTT (cf. C. A. 9, 2787). W. D. C.

Seven years successful operation of double sand filtration plant at So. Norwalk, Conn. H. W. CLARK. *New England Water Works Assoc.* 1915; *Eng. Contr.* 44, 262-3 (1915).—The prevalence of tastes and odors caused by *Asterionella*, *Anabena*, *Dinobryon* and *Aphanizomenon*, particularly from Aug. to Oct., led to the construction of a plant comprizing aeration, filtration through sand (0.35 mm. effective size), aeration, and secondary filtration. For the year ending May 1, 1915, rates of filtration, in mil. gal. per acre, were on primary 3.3, on secondary 10. For a daily av. use of 2.5 mil. gal. the cost was \$5.23 per mil. gal. filtered. LANGDON PEARSE.

New filter and fixation process for plankton. C. M. LÜTTGENS. *Mikrokosmos* 1915-16, 25.—A filtration app. is described with illustrations. The advantages claimed for the process consist in the fact that a practically automatic sepn. of the plankton is accomplished and the organisms are prevented from drying out on the filter. The app. may also be directly used for the fixation of the plankton present on the filter. C. A. NOWAK.

Practical process for sterilization of polluted waters in the field. ROLLAND. *J. pharm. chim.* 12, 179-82 (1915).—Water in a barrel is treated with sufficient excess of $CaOCl_2$ of known strength to impart to the H_2O a distinct Cl taste. It then runs into a large funnel containing absorbent cotton, and upon a perforated disk, alternate layers of finely powdered charcoal, fine sand, powdered charcoal, coarse sand, again wood charcoal, crushed stone and straw to distribute the water. S. WALDBOTT.

Collective and individual sterilization of water in the field. HENRI PÉNAU. *J. pharm. chim.* 12, 123-32 (1915).—For troupes at rest, several methods may be used: (a) To sterilize 100 l. of clear H_2O , use 10 cc. Javel- H_2O (50 g. Cl per l.) or 2.5 g. $CaOCl_2$ (200 g. Cl per kg.); after 30 min. add 5 g. $Na_2S_2O_3$. (b) For 200 l. of H_2O , use 1 tablet of Pellerin (0.85 g. I); after 30 min. add 2 g. $Na_2S_2O_3$. (c) For brackish, or muddy water, use 5 g. $KMnO_4$ per 100 l., after 30 min. add 5 g. $Na_2S_2O_3$, filter, if possible. The amts. of active Cl or $KMnO_4$ should be doubled if the waters are very suspicious. (d) Hot drinks, e. g., tea are advized in winter. Individual sterilization, for troupes in action is based on the complete germicidal power of $KMnO_4$ (0.1 g. per l.) on colon bacilli at the end of 35 min., and reduction of excess of $KMnO_4$ by $Na_2S_2O_3$. Two powders are used: (1) *gray*: $KMnO_4$ powdered, 50; Na_2SO_4 dry powder, 30; pptd. $CaCO_3$ 20. (2) *white*: $Na_2S_2O_3$ powdered, 35; Na_2SO_4 dry, 35; pptd. $CaCO_3$ 30. The 2 mixts. are filled separately into 2 empty Lebel cartridge cases soldered together at the base,

each numbered plainly. The cases are closed with Al caps which serve as measuring cups. Each case contains enough powder to sterilize 40-50 l. of H_2O . S. W.

Erie water works improvements. *Munic. J.* 39, 358-9(1915).—Prior to introduction of rapid filters 7.06 lbs. $CaOCl_2$ per mil. gals. were used. After filtration only 3 to 3.5 lbs. are required. From 0.15 to 0.6 grain per gal. of $Al_2(SO_4)_3$ are used. Wash water averages 3.22 %: *B. coli* is entirely removed. LANGDON PEARSE.

Manufacture of sulfate of alumina at Columbus water softening and purification works. C. P. HOOVER. *J. Am. Water Works Assoc.* 2, 693-702(1915); *Eng. Contr.* 43, 448-9(1915); see C. A. 9, 495. E. BARTOW.

New water conservation scheme at Fall River, Mass. FAY, SPOFFORD AND THORNDIKE. City Report, Fall River, Mass. *Eng. News* 74, 760-1(1915).—A report of the Watuppa Ponds and Quequechan River Commission providing for regulation and storage of pure water supply from ponds, the diversion of sewage from the river, and the handling of condenser water. Oil separators were studied. LANGDON PEARSE.

Lowell filtration plant. W. B. CONANT. *Munic. J.* 39, 613-5(1915).—This plant is designed to remove Fe and Mn from H_2O . The plant has a daily capacity of 8 mil. gal. and includes six coke prefilters, two settling basins and six sand filters. The raw water contains Fe 1.6 and Mn 3.26 p. p. m. The entire cost is \$225,000 with an annual cost of \$18,225 or \$8.60 per mil. gal. LANGDON PEARSE.

Water supply and power at Medicine Hat. *Can. Eng.* 29, 509-14(1915).—The plant includes a standard 6 mil. gal. rapid filter. LANGDON PEARSE.

Small mechanical filter plant, Franklin Furnace, N. J. R. H. EURICH. *Eng. News* 74, 776-9(1915).—This plant has a capacity of 150,000 gals. per day, comprising a coagulation basin provided with perforated baffles, a clear well with 90,000 gals. capacity and 2 filter units. These run alternately for 12 hrs. each, then are washed with water at a vertical rate of 2 ft. per min. Bacterial counts show 0 to 3 per cc. on lactose agar after 48 hrs., *B. coli* negative in 10 cc. L. PEARSE.

Sooke Lake water supply for Victoria, B. C. C. H. RUST. *Am. Soc. Munic. Improvements* 1915; *Eng. News* 74, 996-9(1915); *Can. Eng.* 29, 590-2(1915).—An engineering description of a project costing \$2,500,000, serving 50,000 people, including storage reservoir, pipe line and appurtenances. A watershed of 15,000 acres was purchased at \$12 per acre to protect the supply. LANGDON PEARSE.

Water undertakings of England and Wales. ANON. *Surveyor* 48, 180-1, 247-51 (1915).—Abstracts from and comments on a Government report (House of Commons, Blue Book, ordered printed July 28, 1914) which gives full details of every public water supply in England and Wales. W. D. C.

Water-borne typhoid in Sacramento, Calif. N. E. WILLIAMSON. *Bull. Calif. State Bd. Health*, July, 1915; *Eng. Contr.* 44, 314(1915).—The use of 2.9 lbs. Cl per mil. gal. river water has reduced markedly an average typhoid fever death rate of 53.5 per 100,000. Typhoid fever cases were reduced 73%. The turbidity of the raw water varies from 50 to 1000 parts per mil. LANGDON PEARSE.

A water-borne dysentery epidemic. H. A. WHITTAKER. *Public Health Reports* 30, 3473-5(1915).—Eighty cases of dysentery were caused in the St. Paul Union Stock Yards by contaminated river water entering a pure water system through a fire connection. LANGDON PEARSE.

Water-supplies and health in Massachusetts. A. L. GAMMAGE. *Eng. News* 74, 1077-9(1915).—Data available in Mass., between 1904 and 1913, show no difference in the effect on public health of hard and soft waters, with hardness ranging from 4

to 150 parts per mil. The lowest typhoid and total death rates were found with waters of the least color. LANGDON PEARSE.

Permanent sediment records for water and sewage. G. C. WHIPPLE AND J. W. M. BUNKER. *Am. J. Pub. Health* 5, 989-93(1915); cf. *C. A.* 9, 340.—The Wizard sediment tester is used. It consists of a cotton disk, as a filter medium, held between 2 supports of wire cloth in a cap attached to a milk bottle. The H_2O is placed in the bottle and allowed to flow through the cotton. The amt. of H_2O to use depends upon the clearness of the H_2O , the presence of algae, etc. In the case of sewage less is used. The method is very good in the case of testing filter effluents. J. GAUB.

Sewage works operation and analytical methods. Committee report. W. L. STEVENSON, Chairman. *J. Am. Pub. Health Assoc.* 5, 935-43; *Eng. News* 74, 591-2; *Can. Eng.* 29, 498-500; *Eng. Record* 72, 316-7; *Munic. J.* 39, 434(1915).—The committee recommends detailed reports under the supervision of state boards of health and suggests special analytical methods for sewage works control. E. BARTOW.

Technical apparatus for the purification of waste water. P. ROHLAND. Stuttgart. *Chem. App.* 2, 235-7(1915).—A description of a testing pipe for submitting various materials to the action of waste H_2O to det. its deleterious effect, and of the Halvor Breda dosing app. for automatically adding the correct amt. of colloidal clay, or other purifier, to the H_2O . Cf. *C. A.* 8, 2014. J. H. MOORE.

Disposal of suspended matter in sewage. RUDOLPH HERING. *Intern. Eng. Congress* 1915; *Can. Eng.* 29, 644-8(1915).—H. summarizes the state of the art of sewage disposal, showing that with sanitary collection and delivery of sewage, the proper velocities in sewers being maintained, the liquid can be disposed of in a sanitary manner without nuisance. The materials separate into floating and suspended matter and liquid. Double-deck tanks prove most successful, provided the sludge be kept alkaline. Pptn. by chemicals is sometimes desirable. LANGDON PEARSE.

The action of certain bacteria on sewage. E. G. BIRGE. *Am. J. Pub. Health* 5, 1048-56(1915).—B. studied the effects of *B. coli communis*, *B. cloacae*, *B. pyocyaneus*, *B. proteus vulgaris*, *B. mesentericus ruber*, and *B. subtilis* on fresh, filtered and sterilized sewage under aerobic and anaerobic conditions, also in pure and in symbiotic cultures, observing their effects on free NH_3 , organic N, NO_2 and NO_3 . From the results it appears possible to predict what the changes in the chem. compn. of the sewage are going to be if a certain group or species of bacteria is predominant. *B. subtilis* can be used to good advantage in the treatment of sewage. J. GAUB.

Activated sludge. O. J. WILKINSON. *Eng. News* 74, 948(1915).—W. calls attention to the similarity of sprinkling filters to activated sludge, in that both depend upon the passing of sewage in thin films over active sludge. Grit should be removed. Uniform contact and distribution are requisite. The cost is not yet definitely known. LANGDON PEARSE.

Activated sludge treatment for the packing-house wastes. *Eng. News* 74, 1148(1915).—At the Chicago Stockyards, Armour & Co. have a 20,000 gal. exptl. plant. LANGDON PEARSE.

Choosing air compressors for activated sludge tanks. CARL H. NORDELL. *Eng. News* 74, 904-6(1915).—Reciprocating and hydraulic air compressors, turbo-blowers and positive pressure blowers are discussed. Positive pressure blowers are useful in small installations while turbo-blowers are best for large plants. LANGDON PEARSE.

Recovery of fat in sewage slimes. ROBERT COHN. *Pharm. Ztg.* 60, 424-5(1915).—Expts. made with material from Barmen-Elberfeld sewage point to a probable yearly recovery among other things of some 1277 tons raw fat from a daily treatment of 250 cu. meters of slime. W. O. R.

The utilization of the constituents of city sewage. EDWARD R. BESEMPFELDER. *Chem. Ztg.* 39, 813-5(1915).—The scheme outlined is to have traps in the waste H_2O pipes from kitchens, etc., to catch the oils and grease before they are mixed with the sewage, the traps to be emptied regularly by authorized persons. The sewage is then settled, the clear H_2O used as fertilizer, the greases extd. from the sediment and the residue, containing about 50% H_2O , coked in rotary calciners, the coke passing to water-gas generators. The products are tar, NH_3 , gas, and slag containing K, suitable for fertilizer. From tests on a large scale at Elberfeld B. estimates the yearly saving for Germany in crude fats, gas and $(NH_4)_2SO_4$ at about \$30,000,000. Cf. *C. A.* 3, 440; 4, 72, 804, 3268; 5, 341, 1146; 6, 1483; 7, 191, 192, 671, 882; 8, 542, 543, 1498, 2440, 3700. J. H. MOORE.

Separation of grease from sewage. P. N. DANIELS AND J. B. ROSENFELD. *Cornell Civil Eng.*, Oct. 1915; *Can. Eng.* 29, 541-3(1915).—Barrel expts. were conducted on the use of $Al_2(SO_4)_3$ (50 g. per 40 gal.), and SO_2 (2 oz. per 40 gal.). After 24 hr. settling, 4590 lbs. solid were recovered per million gals. of which 1046 lbs. were grease. The suspended matter was 170 parts per mil. The cost estimate for a plant to handle 3 mil. gal. daily was \$59,000, for annual needs \$56,670; the revenue is estd. at \$38,905. Although effective, SO_2 and alum are too expensive. LANGDON PEARSE.

Relative stabilities in polluted waters carrying colloids. ARTHUR LEDERER. *Can. Eng.* 29, 573-5(1915); see *C. A.* 9, 2785. LANGDON PEARSE.

Stream pollution by surface drainage. G. H. NORTON. *Am. Soc. Munic. Improvements* 1915; *Munic. J.* 39, 584(1915); *Eng. Contr.* 44, 327-8(1915); *Can. Eng.* 29, 561.—At times surface drainage becomes as important an element as city sewage in detg. the potability of a water. Treatment of sewage should only be sufficient to prevent undue burden on water purification plants. LANGDON PEARSE.

Dunbar's second report on the waste liquor from the potash industry. C. L. REIMER. *Z. angew. Chem.* 28, I, 241-5(1915).—A criticism of Dunbar's report on the mineralization of streams by waste water of the potash industry (*C. A.* 7, 3395; 8, 541. H. P. CORSON.

Dye for measuring sewage flow. F. E. DANIELS. *Munic. J.* 39, 550-1(1915).—Expts. using Uranin show a horizontal diffusion of a 10% soln. through a travel of 4.5 in. in 14 hrs. Weaker solns. diffused more slowly. This dye is therefore a reliable agent in studying flow through sewage tanks, drains, etc. LANGDON PEARSE.

Coloration of water with Uranin O. W. QUITZOW. *Das Wasser* 1915, 75-6, 95-7; *Wasser u. Abwasser* 10, 3(1915).—The K salt of fluorescein (Uranin) is employed to det. subterranean connections of surface and ground waters, velocities of underground water courses, etc. The dye possesses, however, an insufficient absorption power. For this reason the Na salt is to be preferred. None of these dyes will work in acid soils. In such a case the addition of NaOH is advisable. Helpful directions are given for the application of actual tests. ARTHUR LEDERER.

A summary of the experience gained in the treatment of the wastes from the scouring of wool. H. R. CROHURST AND A. D. WESTON. *Eng. Contr.* 44, 370-6(1915).—This article describes wool, its compn., impurities, handling, scouring, shrinkage, oiling and packing, combing, finishing and weaving. Av. analyses of wool wastes are given with fats from 46,300 parts per mil. down to 30. Suspended matter may run up to 66,000 p. p. m. The quantity varies per 100 lbs. of wool. For treatment, sedimentation separates only gritty matter, generally less than 30% of suspended matter. Chem. pptn. requires excessive amts. of coagulant. Coke and sand filters work only on waste mixed with domestic sewage. Purification by recovery may be by steeping, by use of volatile solvents, by cracking with acid, or by partial evapn. and centrifuging

to separate grit, potash and wool grease (Smith-Leach process). Sewage treatment methods usually fail, but acid recovery of grease may prove profitable when the price of grease is high. The Smith-Leach process may be profitable at times. L. P.

Refuse collection and disposal. *Munic. J.* 39, 722-39(1915).—Complete statistics for cities in U. S. are summarized in tables and text. LANGDON PEARSE.

Experience in refuse collection and disposal with reference to odors. SAMUEL A. GREERLEY. *J. Am. Pub. Health Assoc.* 5, 835-7(1915); *Eng. Contr.* 42, 576(1915).—Effect of odors is largely relative, depending on environment and industrial odors present. Good design followed by clean careful operation is advantageous. L. P.

Marysville, Ohio, sewage treatment plant provides for high degree of purification. E. D. BARSTOW. *Eng. Record* 72, 636-7(1915).—Population is 4000. The plan used involves screening, sedimentation in two-story tanks, treatment in crushed-stone contact beds and the use of the sprinkling filter. The capacity of the plant is 500,000 gals. per day. Steel-bar screens with 1 in. openings are used. The tanks are designed for a 3 hr. settling period and a sludge storage of from 4 to 6 hrs. The four contact beds are each 90 ft. square and are filled with crush stone to a depth of 4 ft. The filters are each 125 × 175 ft. with sand to a depth of 2 ft. The sludge from the tank is dried on beds of stone. The treatment plant cost about \$55,000. FRANK BACHMANN.

The fitting up and working of a sewage works laboratory. JAMES H. EDMONDSON. *Surveyor* 47, 739-41(1915).—The plan of a small lab. is shown, dimensions being given. Brief directions are given for the usual tests. W. D. C.

Refuse incinerator at Portland. *Munic. J.* 39, 774-5(1915).—The 150-ton incinerator cost \$99,900 in 1910. In 1914, the operating expenses were, in cents per ton of material, 30.25 for labor, 3.5 for supplies and repairs. The total expense was \$15,383. LANGDON PEARSE.

Garbage collection and incineration in Sewickley. E. E. DUFF, JR. *Munic. J.* 39, 719-22(1915).—In a town of 5000, a 10-ton incinerator cost 8000. The operating cost of collections and incinerator are 5,324 per year. LANGDON PEARSE.

A year of activated sludge at Milwaukee, Wisc. GEORGE W. FULLER. *Eng. News* 74, 1146-7(1915).—F. accepts the theory of activated sludge as correct, but comments on practice. At Milwaukee 2 to 3 hrs. aeration removes 96 to 99% bacteria, and nitrifies the effluent according to the amt. of air used. Odors are removed. The sludge dries readily. The process may fail through excessive aeration, presence of mineral grit, or insufficient aeration. LANGDON PEARSE.

Activated sludge progress at Houston, Texas. E. E. SANDS. *Eng. News* 74, 717(1915); *Can. Eng.* 29, 503(1915).—A 14,000 gal. tank is in operation. L. P.

Garbage reduction in Columbus, Ohio. T. D. BANKS. *Munic. J.* 39, 846-7(1915); cf. *C. A.* 9, 2413.—The total amt. treated in 1914 was 21,629 tons. The garbage per capita has increased from 190 (1910) to 211 lbs. with an av. daily amt. of 69.3 tons, the daily av. being 46.3 in Feb. and 100.6 in Sept. Grease, hides and tankage were sold, the receipts being 3.085 per ton of garbage, expenditures 1.859 for operating, with a profit per ton of \$1.226. Allowances for depreciation and interest reduce this to \$0.24 per ton actual profit. Analyses are given. L. PEARSE.

Disposal of Greater New York's sewage. C. E. GREGORY. *Mun. Engineers of N. Y. City* 1915; *Munic. J.* 39, 692-4(1915).—The work of the Metropolitan Sewerage Commission and the Bureau of Sewer's Plan is described. Settling or screening will be used. A clean harbor, free from visible slime or floating matter, is sought, with a dissolved O content above 20% satn. Dredging will be used to relieve existing conditions temporarily. N. Y. harbor should care for 7 million people. LANGDON PEARSE.

Electrolytic sewage treatment plant at Durant, Oklahoma. W. L. BENHAM. *Munic. Eng.* 49, 141-6(1915).—This plant handles about 428,000 gal. daily. Details of stability and bacteriological tests are given, showing reductions in bacteria.

LANGDON PEARSE.

Construction and operation of Gloversville sewage works. H. P. EDDY AND H. J. HAMMER. *Eng. News* 74, 744-7, 780-1(1915).—The design, construction and cost, \$188,754, of a 3 million gal. sewage treatment works are given. The plant serves a population of over 20,000. Lack of dilution necessitated a high degree of purity. The plant comprises coarse screens, primary settling tanks (Dortmund type, vertical velocity 8.7 per hr.), fine screens ($1/2$, $1/4$, $1/8$ in. mesh) on tank effluent, dosing tank, sprinkling filter (3 units of total area 3.07 acres, of 1 to $2\frac{1}{2}$ in. crushed limestone, 4.6 ft. deep), secondary settling tanks, and sand filters (3 beds, 3 ft. deep, of total area 2.72 acres). Four sludge beds are provided of total area 2.63 acres. The flow is estimated at 2.75 mil. gal. daily. About 4 cu. ft. of screenings are daily removed from the coarse screens. Nine cu. yd. per mil. gal. of primary tank sludge are caught and from 0.8 to 2.5 cu. yd. secondary tank sludge. The sludge is pumped to sand drying beds. Two sprinkling filters are operated at a time, the third being rested from 2 to 7 days. No odors are noticeable over 200 ft. away. Flies are reduced by the use of CaOCl_2 . Temporary wooden covers are used over the filters in winter. Analyses of effluents are given. Cost of operation per year was \$5179 in 1913 and \$5952 in 1914.

LANGDON PEARSE.

Garbage disposal at Reading, Pa. W. C. MATTHIAS. *Munic. J.* 39, 544-5 (1915).—The incinerators use 1 ton coal to 10 tons garbage. Costs are given.

LANGDON PEARSE.

Albany sewage disposal works. JOHN H. GREGORY. *Eng. News* 74, 692-5 (1915).—The plant is intended to prevent visible nuisance and sludge deposits in the Hudson River. It has a capacity of 30 mil. gal. with a max. of 45 mil. gal., comprizing pumping station, grit chamber, Imhoff tanks and sludge drying beds. A complete engineering description is given.

LANGDON PEARSE.

A comparison between bleach and liquid chlorine disinfection. C. R. AVERY. *Ann. Rep. Prov. Bd. of Health, Ontario* 33(1915); *Can. Eng.* 29, 661 (1915).—A. concludes that if the same amt. of available Cl is present, both bleaching powder and liquid Cl are equally efficient. Detailed results are given.

LANGDON PEARSE.

Hydrocyanic acid gas as a routine fumigant. R. H. CREEL, F. M. LAGET AND W. D. WRIGHTSON. *Pub. Health Reports* 30, 3537-50(1915).— SO_2 , while fairly effective, does not penetrate; it diffuses poorly, giving vermin a chance to survive. Thus it requires an exposure from 6 to 12 hrs. as against 1 hr. by HCN. CO is valueless for lower forms of animal life and requires complicated app. for generation. Both of these fumigants cause danger by fire which is not the case with HCN. HCN is penetrating and very toxic, easily generated, requires little app. and is not destructive to inanimate objects. The effect on human life depends upon the care used in performing the fumigation.

J. GAUB.

A note on the testing of disinfectants. S. RIDEAL AND J. T. A. WALKER. *Am. J. Pub. H.* 27, 1175(1915).—Discussion is invited on the approved technic of the

(1) Use of a buret instead of the pipet; (2) variations in resistance and culture of *B. typhosus*—for the phenol column—life in $2\frac{1}{2}$ and after. Dilns. ranging between 1 in 80 and 1 in 140 may be too affected when the diln. is higher than 1 in 110 or lower than 1 in 100 becomes so attenuated as to call for dilns. higher than 1 in 1000. J. GAUB.

Fertilizer from municipal waste (TURRENTINE) 15.

Apparatus for purifying water. M. B. CRESSWELL. U. S., 1,158,450, Nov. 2. The process includes boiling, skimming and sedimentation.

Apparatus for purifying and aerating water. J. F. QUIGLEY. U. S., 1,161,971, Nov. 30.

Apparatus for purifying and softening water by chemical treatment. R. H. GRAY and A. F. STAHLHUT. U. S., 1,159,929, Nov. 9.

Apparatus for purifying water electrolytically. J. A. MURDOCK. U. S., 1,159,699, Nov. 9.

Filter for purifying water, etc. I. KITSKE. U. S., 1,162,244, Nov. 30. The filtering material is formed of small particles of sawdust, charcoal or charred blood bonded together with a phenol-CH₂O condensation product.

Composition for softening water. G. BUCHNER. U. S., 1,162,024, Nov. 30. A mixt. of borax 20 and Na₂HPO₄ 70 parts is added to H₂O to "soften" it, preferably with 10 parts of Na₂CO₃ or CaCO₃.

Preserving mineral waters containing carbon dioxide. D. M. PERINE. U. S., 1,160,317, Nov. 16. Mineral waters which tend to give off CO₂ and form a ppt. on exposure to the air are charged with CO₂ before much of the natural CO₂ of the H₂O has been permitted to escape and then sealed in bottles under pressure to retain the CO₂ during storage.

Obtaining solids from sewage. J. ORTEN-BÖVING. U. S., 1,161,600, Nov. 23. Sewage sludge is heated under pressure, cooled to about 30° by heat interchange with untreated sludge and then freed from most of its H₂O by settling, decantation and filter-pressing.

Purifying sewage by sedimentation. L. LINDEN. U. S., 1,160,918, Nov. 16.

Apparatus for purifying sewage or other liquids by sedimentation. L. LINDEN. U. S., 1,162,624, Nov. 30.

Fumigating composition. F. SIGNORET. U. S., 1,159,109, Nov. 2. Grains of about 3 mm. in diam. are coated with sol. silicate and the mixt. is dried and molded into blocks or pieces of the desired form for burning.

Disinfectant. P. FLEMING. U. S., 1,162,152, Nov. 30. A mixt. of chlorinated xylenol and chlorinated cresol is used. The mixt. is found to have a greater germicidal action than that of either component alone.

Purifying liquids. H. KRIEGSHKIM. Brit., 17,494, July 23, 1914. Purifying or freeing H₂O from Cl, which has been added for sterilizing purposes, by filtering the H₂O through a microscopically porous body, such as a silicate of Al or a zeolite, which has been coated with or penetrated by a catalyst, such as oxides of Fe, Pb, Co, etc.

Softening water. PERMUTIT AKT.-GES. Ger., 285,377, Jan. 10, 1913. Addition to 280,691 (C. A. 9, 1647). A larger yield of softening agent is obtained by heating alkali silicate solns. with Na₂HPO₄ soln. The resulting ppt. is from 4 to 5 times greater than that obtained according to the principal process.

15. SOILS AND FERTILIZERS.

R. O. E. DAVIS.

Soil fertility. J. E. RUSH. Carnegie Inst. Technology. *Science* 42, 632-4 (1915).—A general discussion of the interrelation of soil physics, chemistry and bacteriology.
W. H. FRY.

Albuminous bases which are formed of organic substances of soils by hydrolysis. A. SCHMUK. *Russ. J. Exp. Landw.* 16, 281-98(1915).—By boiling soil or humic acid a sufficient time with H_2SO_4 , 2 amino acids were isolated and identified. The 3rd amino acid which comes for the most part from albuminous substances was not found. The quantity of arginine and lysine was detd., by calcn. from N, in 3 different soils. The presence of arginine and lysine and the absence of histidine is not an indication for a group characteristic belonging to the class of albuminous combinations; at the same time it is not contradictory to the fact that these substances are formed of soil albumin during its hydrolytic destruction.

W. H. FRY.

A method for the estimation of hygroscopic moisture in soils. W. D. HAIGH. *Roy. Coll. Sci., Dublin. Sci. Proc. Roy. Dublin Soc.* 14, 529-34(1915).— CaC_2 is mixed with soil in an app. which is described, and the vol. of C_2H_2 evolved is detd. This method was compared with the ordinary method of heating in an oven, and it was found that the results obtained by the carbide method were more consistent and agreed more closely between themselves than did the results obtained from the same sample in the oven.

W. H. FRY.

The determination of nitrates in soil. R. S. POTTER AND R. S. SNYDER. *J. Ind. Eng. Chem.* 7, 863-4(1915).—With soils low in nitrates the use of $CaCO_3$ is to be preferred to CaO , and when the colorimetric method is to be used the carbonate is always better. Carbonate in all cases yields as clear and as nearly colorless a soln. as the oxide.

W. H. FRY.

A new method for the determination of lime requirements in soils. W. H. MCINTIRE. *Agr. Exp. Sta., Knoxville, Tenn. J. Assoc. Official Chemists* 1, 417-8(1915); *J. Ind. Eng. Chem.* 7, 864-7(1915).—A stock soln. of $CaCO_3$ is obtained by passing CO_2 through about 10 g. pptd. $CaCO_3$ suspended in 5 l. distd. water. Excess of carbonate is removed by gravity filtration. The clear soln. of dissolved $CaCO_3$ is received in about $1/10$ of its volume of carbonated distd. water. This soln. is kept cool and under pressure. Pipet 100 cc. of the carbonate soln. into a 150 cc. porcelain evapg. dish and add 10 g. of $1/2$ -mm. or 100-mesh soil. Evap. to a thin paste, the mixt. being stirred after the pptn. of the $CaCO_3$ from soln. and again when reaching volumes of about 75 and 50 cc. The paste is then used to effect scouring of the sides of the evapg. dish by means of a rubber tipped glass rod. The soil is washed into a 300 cc. Erlenmeyer flask by means of CO_2 -free distd. water to a volume of about 60 cc. A series of flasks is connected with a shaking device, 5 cc. of 85% H_3PO_4 are added and the liberated residual CO_2 detd. by passage of the gas through 25 cc. of 4% NaOH in a Camp absorption tower, the air passing into the system being first purified of CO_2 . CO_2 -free distilled water is used to increase the volume of 25 cc. NaOH to an amount sufficient to cover the beads before the passage of CO_2 through the absorbent soln. A vacuum of 4 in. is maintained in the app. during the 30 min. agitation and aspiration. The amt. of $CaCO_3$ in 100 cc. of the carbonate soln. is detd. by boiling off the excess of dissolved gas and decomposing the pptd. carbonate by the above procedure. The difference between the added and the residual $CaCO_3$ in the soil is then detd., correction being made for the CO_2 in the atmosphere of apparatus and the carbonate in the NaOH soln.

W. H. FRY.

Report on soils. J. W. AMES. *Agr. Exp. Sta., Wooster, Ohio. J. Assoc. Official Agr. Chemists* 1, 411-7(1915).—Comparative work on methods for detn. of carbonates and organic C is reported.

W. H. FRY.

Report on availability of potash. E. E. VANATTA. *Agr. Exp. Sta., Columbia, Mo. J. Assoc. Official Agr. Chemists* 1, 398-9(1915).—Progress report on pot tests with feldspar.

W. H. FRY.

Report on determination of potash. T. D. JARRELL. Agr. Exp. Sta., College Park, Md. *J. Assoc. Official Agr. Chemists* 1, 400-11(1915).—The work includes tests on the use of denatured alc. for washing K_2PtCl_6 with special reference to denaturing agents, the necessity for the use of HCl in the aq ext., and the perchlorate method. Cf. C. A. 9, 3318. W. H. FRY.

Report on phosphoric acid. A. J. PATTEN, Agr. Exp. Sta., East Lansing, Mich., AND L. S. WALKER, Agr. Exp. Sta., Amherst, Mass. *J. Assoc. Official Agr. Chemists* 1, 360-9(1915).—Comparative work on basic slag by the official gravimetric and molybdic, optional volumetric, Lorenz, and iron citrate methods is reported. Cf. C. A. 9, 3318. W. H. FRY.

Report on neutral ammonium citrate. L. S. WALKER. Agr. Exp. Sta., Amherst, Mass. *J. Assoc. Official Agr. Chemists* 1, 369-75(1915).—The results of comparative work on 3 fertilizers are given. W. H. FRY.

Triammonium citrate. ROBERT A. HALL. Univ. Minn., Minneapolis, Minn. *J. Assoc. Official Agr. Chemists* 1, 375-80(1915).—Dry NH_3 gas was passed into an abs. alc. soln. of citric acid. Triammonium citrate was thus pptd. quant. The properties and analysis of the salt are given. W. H. FRY.

Report on nitrogen. R. N. BRACKETT, Agr. Exp. Sta., Clemson Coll., S. C., AND H. D. HASKINS, Agr. Exp. Sta., Amherst, Mass. *J. Assoc. Official Agr. Chemists* 1, 380-96(1915).—Comparative results of various methods for detg. N are given and discussed. W. H. FRY.

Analysis of nitrogen in leather waste. R. P. ROSE. Mellon Inst., Pittsburgh. *J. Assoc. Official Agr. Chemists* 1, 396-8(1915).—Neutral and alk. permanganate methods are compared. W. H. FRY.

The interpretation of soil analyses. G. S. FRAPS. Agr. Exp. Sta., College Sta., Tex. *J. Assoc. Official Agr. Chemists* 1, 418-21(1915).—The estn. of the total N, the active P_2O_5 , the active K_2O and the acid consumed of the soil at present affords the best measure of the soil fertility and the best means of judging of its deficiencies. W. H. FRY.

Report on nitrogenous compounds of soils. C. B. LIPMAN. Agr. Exp. Sta., Berkeley, Cal. *J. Assoc. Official Agr. Chemists* 1, 422-4(1915).—Methods for the detn. of NH_3 , nitrites, nitrates, and total N, are discussed. W. H. FRY.

Report on alkali soils. R. F. HARE. Agr. Exp. Sta., State Coll., N. Mex. *J. Assoc. Official Agr. Chemists* 1, 424-6(1915).—Results of a comparison of methods for black alkali are given. Cf. C. A. 9, 3316. W. H. FRY.

A review and discussion of some of the methods for the determination of alkali in soils. R. F. HARE. Agr. Exp. Sta., State Coll., N. Mex. *J. Assoc. Official Agr. Chemists* 1, 426-34(1915).—Various necessary detns. are discussed. W. H. FRY.

Influence of growth of cowpeas upon some physical, chemical and biological properties of soil. C. A. LECLAIR. Univ. Mo. *J. Agr. Research* 5, 439-48(1915).—Cowpeas (*Vigna sinensis*) tend to maintain the friability of loose and compact seed beds. While they take more water from the soil than evaps. from uncultivated adjacent lands, the removal of water is from below the 2nd foot of soil. Land that was plowed and left uncultivated or plowed and seeded to cowpeas contained a greater quantity of nitrates in the soil at the end of the season than unplowed land similarly treated. The bacterial activities of the soil upon which cowpeas were grown tended to show that the soil organisms are probably a factor in preventing the packing of soil, as also is the mechanical shade effect of the crop grown upon the land. W. H. F.

Changes in soils brought about by heating. A. WILSON. *Sci. Proc. Roy. Dublin Soc.* 14, 513-20(1915).—Part of the increased productivity of heated soil may be due to

the increase in sol. matter induced by heating, and to the change in soil texture, which has a remarkable effect on the retention of water by the soil. The increase in the amt. of sol. matter is seen in (a) the range of coloration of the solns. extd. from soil heated at different temps.; (b) the increase in elec. cond. of the soln.; (c) the increased depression of f. p. found in exts. from soil heated at the higher temps. About half the total depression throughout the expts. is due to electrolytes. W. H. FRY.

Soil temperature as influenced by cultural methods. JOSEPH OSKAMP. Purdue Univ. Agr. Expt. Sta. *J. Agr. Research* 5, 173-80(1915).—Temp. records were taken under natural field conditions during a period of 2 years on 3 plots in a young apple orchard as follows: (1) Tillage with a cover crop, (2) straw mulch and (3) grass land. The data are given. It is concluded that a system of clean cultivation with a winter cover crop is characterized by extreme diurnal and annual fluctuations in soil temp., and that a straw mulch equalized these fluctuations to a marked extent, as does also a grass crop, though in less degree. W. H. FRY.

Soil temperature. J. W. LEATHER. *Mem. Dept. Agr. India (Chem. Ser.)* 4, 19-84(1915).—Temp. changes in a highly calcareous soil in the alluvium of Pusa are recorded. Comparisons are made between a fallow soil and one growing oats and hemp by means of max. and min. thermometers. There is a close correspondence between the temp. of fallow soil at 1 inch from surface and that of the air in the shade. The soil minimum is about 2° higher than the air and the soil max. about 3° higher than the air max. The diurnal change at 1 in. depth is about 1.5° greater in the soil than in the air. A change in the sp. ht. of the soil, due to change of moisture content, does not effect the max. or min., but rainfalls during the dry season have a marked effect. The effect of a covering crop on soil temp. prevents the surface soil from rising to the temp. which fallow land assumes and also modifies the diurnal change. The temp. of exposed soil at 1 in. depth rises 3° above that of air and that of cropped land about 2° below it. J. J. SKINNER.

Some problems of forestry soil science (a critical consideration). G. A. R. BORGESANI. Rome. *Internat. Mitt. Bodenkunde* 5, 225-31(1915).—Forest litter is considered. Transformation processes, measure, and appropriateness of removal are discussed. W. H. FRY.

Fertilizers. A. MCGILL. Inland Revenue Dept., Ottawa, Canada, *Bull.* 317, 45 pp.(1915).—Of 420 samples analyzed 398 were accepted as satisfactorily meeting their guarantee. E. H.

Fertilizer from municipal waste. J. W. TURRENTINE. *U. S. Dept. Agriculture Year Book* 1914, 295-310; *Munic. J.* 39, 739-40(1915); cf. *C. A.* 9, 2558.—Street sweepings are low in fertilizer value and may contain mineral oil. Dead animals are valuable; garbage, when treated by the reduction process, may be. Av. costs are quoted. LANGDON PEARSE.

Report on insecticides. R. C. ROARK. Bur. Chem. *J. Assoc. Official Agr. Chemists* 1, 435-57(1915).—This work includes a study of methods for the detn. of moisture, CO₂, Cu, arsenic and lead oxide as they occur in one or more of the following: Bordeaux, Bordeaux-lead arsenate, and Bordeaux-Paris green. Work was also done on the comparison of new methods for the detn. of nicotine, and of arsenious oxide in Paris green, with the present official methods. W. H. FRY.

Chemical Abstracts.

and enriching phosphate fertilizers. M. M. HAY and T. L. WILSON. 1473, Nov. 28. Mono-Ca phosphate or similar phosphoric fertilizer materials in a closed chamber and NH_3 and air are passed through the material under no effect absorption of the NH_3 .

Utilizer. S. B. NEWBERRY and H. N. BARKETT. U. S. 1,158,711, Nov. 2. The rock is heated to 1400-1650° with 5-15% its wt of hydronitride, carbonate of Na or K. The alkali metal compounds are volatilized and the phosphate is citrate-sol.

16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Progress in the chemistry of the fermentation industry in 1914. A. BAUDOUIN. E. H. gew. Chem. 28, I, 437-40. 445-8. 455-6 (1915).—Col-

Wine. B. G. HARTMANN. J. Assoc. Official Agr. Chemists 1, 131-8 (1915).—Col-
 ative work on the Hartmann-Eoff method for tartaric acid in wine was found to
 satisfactory results in white wines. The method is as follows: Titrate the acidity
 e wine after bringing to incipient boiling, with 0.1 N NaOH, using phenolph.
 ure 50 cc. into a 250 cc. beaker, completely neutralize with N NaOH and make
 100 cc. Multiply the number of cc. of N NaOH used above by 0.075, weigh this
 in g. of tartaric acid (prepd. by drying powdered acid for 2 hrs. in water oven;
 dissolve it in 50 cc. of the neutralized and dild. wine. After soln. add 15 g. of KCl
 1 cc. of glacial AcOH and stir until dissolved. Add 20 cc. of 95% alc., stir 1 min.
 side for 15 hrs., to collect cream of tartar crystals, filter and titrate the crystals
 0.1 N NaOH, using phenolph. Add to the buret reading 1.5 cc. and multiply by
 From this subtract the tartaric acid added and multiply by 2 to get the results
 in the sample. Analyses of 2 wines by this method agreed closely with results
 ed by the Kling racemate method (C. A. 4, 1590). Collaborators suggested the
 on of Rochelle salt instead of tartaric acid to convert all the tartaric acid present
 wine to bitartrates, and also the possibility of stirring the soln., to ppt. the cream
 tar, with a mechanical stirrer to supplant the standing for 15 hr. without for-
 accuracy when the acid present exceeds 0.1 g. per 100 cc. of the sample. Data
 free tartaric acid and cream of tartar in the wine from the total tartaric acid
 above and alkalinity of the ash are also given.

does the coloring matter in grape wine. A high citric acid content and a low tartaric and tannic acid content indicate its use as an adulterant in grape wine. H. N. E.

Beer. J. G. RILEY. *J. Assoc. Official Agr. Chemists* 1, 138-43 (1915).—Collaborative work on phosphoric acid in beer showed that the method by which 25 cc. of beer measured at 15.6° and free from CO₂ is ashed after the addition of 25 cc. of standard Ca acetate soln. and the P₂O₅ detd. volumetrically in the ash after soln. in HNO₃ gives more concordant results than the uranium acetate, straight ashing, or wet combustion methods. The analyses given indicate that a beer made from malt, 55% (by wt.) with corn, 45% contains about 1/2 as much phosphoric acid as a straight malt beer. This method has been recommended as the official method for phosphoric acid in beer. H. A. L.

A cause of sluggish fermentation. ED. MOUFANG. *Allgem. Z. Bierbr.-Malzfabr.* 43, 305-8, 313-4 (1915).—Sluggish fermentation was observed in a number of cases, when the malt employed was prepd. from barley which had not been dried before malting. The trouble could not be remedied by different mashing methods, but was eliminated when steam-cooking of the wort was replaced by direct fire or steam pressure cooking. M. sees the cause of sluggish fermentations in his cases in the presence of a colloidal substance which is not pptd. by steam-cooking in the ordinary way.

L. W. HAAS.

Methodics of the biological examination of brewing waters. H. WILL. *Z. ges. Brauw.* 38, 329-31, 337-40 (1915).—In his exptl. work W. finds that the microorganisms in the same brew water may behave in a widely different manner towards different beer worts. The biol. exam. of brew-waters therefore may lead to a totally wrong interpretation as to the biol. condition of a brew-water, whenever a foreign wort is used in the tests.

L. W. HAAS.

The determination of ammonia in wine and its significance. W. I. BARAGIOLA AND C. GODET. *Z. Nahr.-Genussm.* 30, 169-216 (1915).—A survey with a good bibliography is given of the work hitherto done on NH₃ detns. in wine and in other biochemical fields. Six methods were used by the authors in their work: (1) Distn. *in vacuo* with MgO: Place 100 cc. of wine and 5-10 g. of freshly ignited MgO in a liter Claisen flask having 2 necks; use a liter suction flask containing 10 cc. 0.2 N H₂SO₄ surrounded with ice water as a receiver, and a second suction flask connected with the suction pump as a safety flask; fit a capillary tube extending to the bottom of the flask into the second neck of the Claisen flask, the tube being connected with a gas wash bottle contg. H₂SO₄. Distil at 15 mm. (Hg) pressure in a water bath heated to about 40°, until a residue of about 15-20 cc. remains in the flask, washing out the app. at the end with a stream of air. Titrate the distillate with 0.1 N alkali using Congo red. (2) Distn. *in vacuo* with Na₂CO₃ and NaCl: Charge the distn. flask with 100 cc. wine, 20 g. NaCl and 15 cc. of satd. Na₂CO₃ soln. proceeding as above. (3) Distn. in steam with NaOH: Place 100 cc. of wine, 400 cc. of water, and 20 cc. NaOH (sp. gr. 1.3) in a liter flask and distil the NH₃ into 0.2 N H₂SO₄. (4) Pptn. of NH₄ as MgNH₄PO₄: For exact analysis the free NH₃ must be sepd. from amines and other bases in the distillate by pptn. as MgNH₄PO₄ and the NH₃ therein subsequently titrated. (1) is sufficiently accurate for food inspection and technical work since the true NH₃ content is only slightly increased by amino compds. and other bases carried over in the distn. (5) Distn. with MgO at ordinary pressure: Follow the usual procedure. (6) Pptn. of the NH₄ in the distillate of (1) and (4) with PtCl₄: Follow the usual procedure. The NH₃ content of sound wines varies from none to 150 mg. N per l. The French limit of 20 mg. is untenable. Fruit wines are especially low in NH₃. The detn. of NH₃ has a large significance in the "balancing" of acids and bases in wine in physico-chem. investigations.

L. D. ELLIOTT.

Drying and enriching phosphate fertilizers. M. M. HAFF and T. L. WILLSON. U. S. 1,161,473, Nov. 28. Mono-Ca phosphate or similar phosphatic fertilizer materials are placed in a closed chamber and NH_3 and air are passed through the material under pressure to effect absorption of the NH_3 .

Fertilizer. S. B. NEWBERRY and H. N. BARRETT. U. S., 1,158,711, Nov. 2. Phosphate rock is heated to $1400\text{--}1650^\circ$ with 5-15% its wt. of hydroxide, carbonate or sulfate of Na or K. The alkali metal compds. are volatilized and the phosphate rendered citrate-sol.

16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Progress in the chemistry of the fermentation industry in 1914. A. BAUDREXEL. *Z. angew. Chem.* 28, I, 437-40, 445-8, 455-6(1915). E. H.

Wine. B. G. HARTMANN. *J. Assoc. Official Agr. Chemists* 1, 131-8(1915).—Collaborative work on the Hartmann-Eoff method for tartaric acid in wine was found to give satisfactory results in white wines. The method is as follows: Titrate the acidity of the wine after bringing to incipient boiling, with 0.1 *N* NaOH, using phenolph. Measure 50 cc. into a 250 cc. beaker, completely neutralize with *N* NaOH and make up to 100 cc. Multiply the number of cc. of *N* NaOH used above by 0.075, weigh this result in g. of tartaric acid (prepd. by drying powdered acid for 2 hrs. in water oven) and dissolve it in 50 cc. of the neutralized and dild. wine. After soln. add 15 g. of KCl and 2 cc. of glacial AcOH and stir until dissolved. Add 20 cc. of 95% alc., stir 1 min., set aside for 15 hrs., to collect cream of tartar crystals, filter and titrate the crystals with 0.1 *N* NaOH, using phenolph. Add to the buret reading 1.5 cc. and multiply by 0.015. From this subtract the tartaric acid added and multiply by 2 to get the tartaric acid in the sample. Analyses of 2 wines by this method agreed closely with results obtained by the Kling racemate method (*C. A.* 4, 1590). Collaborators suggested the addition of Rochelle salt instead of tartaric acid to convert all the tartaric acid present in the wine to bitartrates, and also the possibility of stirring the soln., to ppt. the cream of tartar, with a mechanical stirrer to supplant the standing for 15 hr. without forfeiting accuracy when the acid present exceeds 0.1 g. per 100 cc. of the sample. Data to calc. free tartaric acid and cream of tartar in the wine from the total tartaric acid as detd. above and alkalinity of the ash are also given. H. A. LEPPER.

Report on wine. B. G. HARTMANN. *J. Assoc. Official Agr. Chemists* 1, 485-90(1915).—Further study on methods for the detn. of tartaric acid in wines and also the use of dry phenolph. as an indicator for detg. the acidity of highly colored solns. The results of collaborative work show that the bulletin method for tartaric acid is entirely unreliable in solns. containing free phosphoric acid. The two methods of Hartmann and Eoff, (1) one-half neutralized and (2) completely neutralized, although giving fairly good results are far from satisfactory. In the detn. of the total tartaric acid content in alc. mixts., sapon. of the esters must precede the final detn. The indicator for acidity seems to be very satisfactory and promises to fill a long felt want in the analysis of highly colored solns. H. R.

The extraction and composition of elderberry wine from the province of Schleswig-Holstein. G. MAUE. *Z. Nahr.-Genussm.* 30, 231-4(1915).—The process of manuf. of elderberry wine takes from Oct. to March for its completion. After the is extd. it is necessary to add sugar but not a yeast to bring about fermentation. Analyses are given. The coloring in elderberry wine responds in the same way to reagents

does not stain. At rest, the volutin occurs mostly in the form of large drops, while in vital cells it is distributed in small droplets over the whole vacuole wall; in this latter condition it is only visible after staining. The volutin drops are distinguished from fat globules by their smaller refraction of light. In stored yeasts the volutin gradually disappears, first at the surface of the bulk of yeast. In spite of this fact volutin is no real reserve material. Stored yeast retains for some time the capacity of restoring in aq. sugar solns. larger quantities of volutin than it originally contained. With fermenting yeast the volutin is in fine distribution, clinging to the vacuolar walls. The presence of sugar puts the volutin almost instantaneously in this condition and position, indicating that the vacuoles are the probable places of the formation of alc. and CO_2 . The more volutin present, the higher the fermenting power of yeast. Bottom beer-yeast is always richer in volutin than common compressed yeast. In plain sugar solns., the quantity of volutin increases, reaching a max. after 1.5 to 2.0 hrs. After 2 hrs., a translocation takes place, the volutin being pressed to the cell wall by the accumulating glycogen. Later a decrease is observed, due to the passing of volutin over to daughter cells and to assimilation. A decrease due to fermentation alone could not be established. In the presence of certain salts (stimulants or nutriment for yeast) the formation of volutin is decidedly stimulated. K_2HPO_4 proved to be a specific "volutin former." Peptone added to wort decidedly increases the volutin content of the cells. In volutin-free cells, the former is formed in very small droplets. Daughter cells receive it always by translocation from the mother cells; spores, too, receive part of their volutin. The volutin remains preserved in yeast dried without application of heat. On heating living cells, it disappears at 60° . In amoebae-eating yeast, fat and volutin accumulate, indicating difficult digestibility or non-digestibility of both. With culture yeasts, fermenting power and volutin content are closely related, and it is obvious that the volutin must be the fermentation enzyme itself or its zymogen or another substance playing a very important role in fermentation. With some species of lactic bacteria, a relation between volutin content and acidity produced could be established and also with acetic bacteria examd. From these facts it seems that the volutin with different molds is different. In these cases the metachromatism would be a general reaction for a certain group of enzymes (as, e. g., the guaiacum reaction for oxidases).

L. W. HAAS.

Maraschino. J. G. RILEY AND L. SULLIVAN. *J. Assoc. Official Agr. Chemists* 1, 490-6(1915).—The methods of manuf. of genuine and imitated maraschino are briefly reviewed and the analyses of 10 samples of genuine Dalmatian maraschino, 9 samples of the French, 4 of the Dutch and 3 of the American products are given. The following conclusions are drawn: Dalmatian maraschino prepd. from the marasca cherry has a delicate fragrance and aroma and a distinctive flavor which is different from products prepd. from other varieties of cherries and fruits. Such maraschino may contain traces of BzH and HCN . The amt. of congenics (acids, esters, aldehydes, furfural and fusel oil) is low, indicating the use of alc. in the manuf. of the product. The French, Dutch, and American products generally have an entirely different flavor from the Dalmatian product. Genuine maraschino when dild. with water and satd. with NaHSO_3 and extd. with ether imparts its original odor to the ether. If the ether is evapd. at a low temp., the aroma of the original product can be detected. This is a useful test where the BzH flavor is strong, as the NaHSO_3 fixes the BzH and allows the removal of other flavors by means of ether.

L. W. HAAS.

Waterproofing cement beer-fermenting tanks. F. W. RICKERS. U. S., 1,162,515. Nov. 30. The walls of the tank are treated with H_2O for sufficient time to dissolve out the sol. Ca and Mg compds. Then the walls are heated to drive out occluded air and

moisture and while they are still hot are coated with a plastic water-proof lining, *e. g.*, pitch or paraffin.

Saccharifying and fermenting starch. A. C. MOLHANT. *Brit.*, 17,009, July 17, 1914. See U. S., 1,134,281 (*C. A.* 9, 1365).

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

Evodin, a crystalline constituent of the fruits of *Evodia rutacearpa*. Y. ASAHINA AND M. ISHIO. *J. Pharm. Soc. Japan* 404, 1148(1915).—Evodin was first isolated by Keimatsu (*J. Pharm. Soc. Japan* 248 (Oct., 1902)) and found to be insol. in H_2O , alc., ether, petr. ether, and somewhat sol. hot C_6H_6 , EtOAc, HOAc, and $CHCl_3$, m. 285° . The formula as detd. by A. and I., is $C_{17}H_{18}O_4$. The acrid properties are due to an ethereal oil, which A. and I. were unable to isolate on account of its susceptibility to oxidation and tendency toward polymerization. A number of other cryst. compds. were extd. but were not further sepd. They contained over 10% N. An abstr. in German precedes the article. H. W. DAUDT.

Color reactions of furfural and hydroxymethylfurfural. D. SCHENK. *Apoth. Zig.* 30, 382-3(1915).—A discussion of the more important color reactions, with especial reference to their applicability in testing flour. W. O. E.

A comparison of the results secured by the use of chemical and physiological assay methods for tincture of aconite. CHARLES C. HASKELL AND H. W. ZIRKLE. *Am. J. Pharm.* 87, 537-40(1915).—Four samples of tincture of aconite secured from representative manufacturers showed little variation in compn. as detd. by the official method of assay. By tests of these same samples, upon guinea pigs, great variations in toxicity were apparent. The results secured by the guinea-pig test were confirmed by the use of Hatcher's method. The assay process demanded by the U. S. P. for tincture of aconite is not only useless but actually harmful in giving a false sense of security. W. G. GAESSLER.

Concerning two sweet tasting drugs. R. ROBERT. Rostock, Germany. *Am. J. Pharm.* 87, 555-9(1915).—(1) A really hemolytically active saponin does not exist in glycyrrhiza. The only biologically active substance is a preformed prosapogenin, which resides in the bark of the plant. (2) Glycyrrhiza pharmacologically belongs to the group of saponin-containing plants. It is, however, the mildest in the group and consequently the least harmful expectorant of all of them. Properly purified glycyrrhizin is exceedingly sweet, a diln. of 1 in 20,000 still having a lasting pure sweet taste. This property should make it a valuable substitute for saccharin as a sweetening agent. (3) It is practically impossible to distinguish by biological tests the true saponins from preps. made from unpeeled glycyrrhiza. There is, however, a chemical test; namely, the aglykones of glycyrrhizin yield on zinc-dust distn. naphthol derivs., while those of the true saponins appear to be cholesterol derivatives, giving color reactions similar to those of the cholesterol. (4) The fact that the different saponins differ physiologically from each other is of significance to authorities and legislatures. The position taken by the Australian Government, that saponins must be excluded from all food stuffs, has been untenable, since saponins have been found to exist in spinach, lettuce, caraway, etc. Present laws concerning saponins should be so amended as to require that in every case the name of the plant which yields the saponin entering into the food stuffs should be printed on the label. Since the knowledge concerning the individual saponins is steadily growing, it is possible that before long all non-poisonous saponins will definitely be sepd. from the poisonous saponins. W. G. GAESSLER.

Ammonia. AZOR THURSTON. Agricultural Comm. of Ohio. *Ammonia Bull.* July, 1915, 19 pp.—Analyses are given of 157 samples of *aqua ammonia*. The pharmaceutical requirement is 10% by wt. of NH_3 gas. The samples analyzed averaged 5.56% NH_3 gas and only 6% were of standard strength. E. H.

Ernst Ludwig. THEODOR PANZER. *Chem. Ztg.* 39, 857-8(1915).—Died Oct. 14. An obituary. J. H. MOORE.

Progress in the field of tobacco chemistry. RICHARD KISSLING. *Chem. Ztg.* 39, 873-5(1915).—A review, with bibliography. J. H. MOORE.

Thymol. A. DUBOSC. *Mat. grasses* 8, 4314-5(1915).—A consideration of various plants as sources from which thymol may be obtained. E. J. K.

Incorporation of sulfur into vaseline. L. PAUL. *Seifensieder-Ztg.* 42, 868-9, 886-7(1915).—At a temp. of 250-300°, S and vaseline form a black powder. By heating 10 g. of vaseline and 1.5 g. S to 80° the reaction begins but leaves a red-brown residue which, however, changes at 180°, and at 270° the vaseline volatilizes and the heating should cease. The mass can be filtered if 10 cc. petroleum are added. The residue after a second treatment as above is termed V. S. and is a black odorless powder which does not melt at 300°. The petr. ether-sol. matter contains a salve residue which P. terms V. S. L. and which has a sulfurous, burned-rubber odor. A yield of 50% of V. S. can be obtained. The possible uses in pharmacy or the color industry of these preps. has not yet been ascertained. E. SCHERUBEL.

Determination of methyl alcohol (FENDLER) 7. Volatile oil of *Cymbopogon sennaarensis*, Chiov (ROBERTS) 10.

Preserving hops. H. WENNERSTEN. U. S., 1,161,272, Nov. 23. Comminuted hops are formed into a pasty mixt. with warm sugar sirup. The particles are coated with the sirup. The exclusion of the air from the hops results in the better retention of their volatile constituents.

Coating pills and tablets, etc. K. KAWAI and Z. MIWA. U. S., 1,161,690, Nov. 23. A mixt. of gelatin 38, agar-agar 1.5, H_2O 56, sugar 16 and glycerol 36 parts is used in the coating.

Tarry medicinal product from oil of cade. I. BUGARSZKY. U. S., 1,160,992, Nov. 16. Oil of cade is distd. under 20 mm. pressure and the fraction taken which comes over between 220° and 300°. The product has a sp. gr. of 1.053, a honey-like consistency and is completely sol. in alc., CHCl_3 and CS_2 . Cf. C. A. 9, 2424.

Making esters of lactic acid or other similar fatty acids. R. GRÜTER and H. POML. U. S., 1,160,595, Nov. 16. Lactic acid is heated to 107-180° while passing air through it to form anhydride and the latter is then heated under a reflux condenser with alc. containing 2% of HCl to promote the formation of lactic ester. Instead of HCl, $\text{Al}_2(\text{SO}_4)_3$, or titanous acid compds. or anhydride may be used to accelerate the formation of lactic, glycolic or similar esters.

Dihalogen-substituted derivatives of paraffin hydrocarbons. F. E. MATTHEWS and H. J. W. BLISS. U. S., 1,158,524, Nov. 2. The pat. relates especially to the manuf. of $\text{C}_6\text{H}_{11}\text{Cl}_2$ and $\text{C}_6\text{H}_{11}\text{Cl}_3$, which are made by distg. a mixt. of satd. and olefin hydrocarbons such as is produced by cracking mixed satd. hydrocarbons from $\text{C}_{10}\text{H}_{22}$ to $\text{C}_{12}\text{H}_{26}$, in order to obtain relatively pure olefin hydrocarbons, and then treating this fraction with just sufficient Cl (or other halogen) to effect satn. of the unsatd. hydrocarbons.

Diacyldiaminophenol compounds. D. MARON. U. S., 1,159,403, Nov. 9. 3-Acetyl-amino-4-lactylaminophenetole is made by dissolving lactyl-*p*-phenetide in

glacial HOAc, nitrating, reducing and treating the 3-amino-4-lactylphenetide with As_2O_3 . It forms needles m. 139° , sol. in hot H_2O and easily sol. in alc. and acetone. 3-Ethoxycarbonylamino-4-lactylaminophenetole m. $108-9^\circ$. 3-Acetylamino-4-ethoxycarbonylamino-phenetole m. $143-4^\circ$. 3-Acetylamino-4-ethoxycarbonylamino-phenol m. $208-9^\circ$ and 4-acetylamino-3-ethoxycarbonylamino-phenetole m. 115° . All are antipyretics.

α -N-Methylpyrrolidylpropan-1-one. K. HESS. U. S., 1,158,496, Nov. 2. α -N-Methylpyrrolidylpropan-1-one is made by heating an acidulated soln. of α -pyrrolidylpropan-1-ol for 4 hrs. to $115-120^\circ$ with CH_2O , pptg. with alkali and extg. with ether. It is an oily liquid of disagreeable odor, sol. in H_2O and the common org. solvents. It b_{12} $70-5^\circ$ and forms a picrate, m. at 103° . From α -pyrrolidylpropan-2-ol an oily liquid is obtained which b_{14} $79-83^\circ$ and yields a picrate, m. 174° , and an oxime m. at 125° .

Hexamethylenetetramine-silver glycocholate. K. KAUTZSCH. U. S., 1,161,867, Nov. 30. A colorless or slightly colored powder is made by reaction together of Ag glycocholate and $(\text{CH}_2)_6\text{N}_4$ or of Ag_2O , glycocholic acid and $(\text{CH}_2)_6\text{N}_4$. It is readily sol. in H_2O , in hot 90% alc. and in MeOH and almost insol. in ligroin and is decompd. with HCl in aq. soln. with formation of $(\text{CH}_2)_6\text{N}_4\text{-HCl}$, AgCl and glycocholic acid.

Silver-ammonium glycocholate. K. KAUTZSCH. U. S., 1,161,866, Nov. 30. A colorless powder of the formula $\text{C}_{26}\text{H}_{39}\text{O}_7\text{CO.NH.CH}_2\text{COOAg(NH}_2\text{)}$ is made by reaction of NH_4OH on Ag glycocholate, or NH_4 glycocholate on Ag_2O or Ag_2SO_4 on Ba glycocholate and NH_4OH . It m. at about 195° while effervescing and darkening in color, is readily sol. in H_2O and hot 90% alc., more difficultly sol. in cold 90% alc., insol. in ether, C_6H_6 and toluene and is decompd. in aq. soln. with HCl, yielding NH_4Cl , AgCl and glycocholic acid.

Apparatus for manufacturing alcohol in solid form. G. MORFURGO. Aust., 7,653, Nov. 13, 1914. Separately prepared alc. solns. of NaOH and stearic acid are mixed cold, so that the Na stearate forms after mixing, whereupon the mass, at first semi-liquid and gelatinous, solidifies to a homogeneous product.

Arsenobenzene derivatives. C. F. BOEHRINGER & SÖHN. Brit., 15,657, June 30, 1914. 2,2-Dihalo-4,4'-bismethylamino-3,3',5,5'-tetraaminoarsenobenzenes, useful in therapeutics, are prepd. by nitrating a 2-halogen-4-methylaminobenzene-1-arsenoxide or -1-arsonic acid, or a deriv. of either compd. containing a 2nd Me group or an acid residue attached to the N atom, and reducing with strong reducing agents the 2-halo-4-methylnitroamino-3,5-dinitrobenzene-1-arsonic acid resulting. The prepn. of the Cl compd. is described. 2-Halo-4-dimethylaminoarsenobenzene-1-arsenoxide is prepd. by heating *m*-halodimethylaniline with AsCl_3 . 2-Halo-4-dimethylaminobenzene-1-arsonic acid is prepd. by oxidation of the corresponding arsenoxide.

Urea derivatives. BAYER & Co. Brit., 13,866, June 8, 1914. Urea derivs. of the naphthalene series are prepd. by the action of COCl_2 upon derivs. of 1,8-aminonaphtholsulfonic acids containing 1 or more aminobenzenesulfonyl groups or derivs. thereof, in place of some or all of the aminobenzoyl residues referred to in 9,472, 1914 (C. A. 9, 2697). In examples *m*-aminobenzenesulfonyl-, and *m*-aminoanisoyl-*m*-aminobenzenesulfonyl derivs. of 1,8-aminonaphthol-3,6-disulfonic acid are treated with COCl_2 . The products are useful in therapeutics. Nitro- and aminobenzenesulfonyl derivs. of 1,8-aminonaphthol-3,6-disulfonic acid are prepd. by treating the acid with *m*-nitrobenzenesulfonyl chloride, and subsequently reducing the product. *m*-Nitro- and *m*-aminoanisoyl-*m*-aminobenzenesulfonyl derivs. of 1,8-aminonaphthol-3,6-disulfonic acid are prepd. by treating *m*-aminobenzenesulfonyl-1,8-aminonaphthol-3,6-disulfonic acid with *m*-nitroanisoyl chloride and subsequently reducing the product.

Ureas. FABRIQUES DE PRODUITS DE CHIMIE ORGANIQUE DE LAIRE. Brit., 17,501, July 23, 1914. Ureas of the general formula $RR^1N.CO.NR^2R^3$, where R, R^2 = alkyl and R^1 , R^3 = aryl, are prepd. by the usual methods, *e. g.*, by forming an alkylarylurea chloride and condensing this with a 2nd alkylarylamine. According to examples: ethylphenylurea chloride is prepd. from ethylaniline and $COCl_2$ and is condensed with methyl-*o*-toluidine; methylphenylurea chloride is similarly prepd. and condensed with ethyl-*o*-toluidine; diethyldi-*o*-tolylurea may also be obtained by the action of 1 mol. of $COCl_2$ on 4 mols. of ethyl-*o*-toluidine. The products are liquids or solids of low m. p., and are suitable for stabilizing nitro compds., or nitric esters, *e. g.*, nitrocellulose explosives, celluloid, etc.; they readily absorb nitrous fumes.

Alcamines; alcamine esters. A. B. DAVIS. Brit., 17,085, July 18, 1914. Alcamines and esters thereof of the general formula $R^1R^{II}N.CH_2C(OR^{IV})(R^V).CH_2.CH_2.R^V$, where R^1 , R^{II} = alkyl, aryl, or one of them = H, R^V = alkyl, aryl, or aralkyl, R^{IV} = H or acyl, are prepd. by treating chloromethyl ω -bromopropyl ketone with an alkyl, aryl, or aralkyl Mg halide, condensing the resulting chlorohydrin with an amine to produce the alcamine, which may then be esterified; the ester may be converted into salts, such as the HCl. According to an example, the parent materials used are chloromethyl ω -bromopropyl ketone, $EtMgBr$, Me_3NH and $BzCl$. Cf. C. A. 9, 2696.

Alcamine esters. A. B. DAVIS. Brit., 17,086, July 18, 1914. Alcamine esters of the general formula $R^1R^{II}NCH_2C(OR^{IV})R^{III}CH_2CH_2CHMe_3$, where R^1 , R^{II} = alkyl, or one of them = H, R^{III} = alkyl, aryl, or aralkyl, and R^{IV} = acyl, are prepd. by treating chloromethyl isoamyl ketone with an alkyl, aryl, or aralkyl Mg halide, condensing the resulting chlorohydrin with an alkylamine to produce the alcamine, and esterifying; the ester may be converted into salts such as the HCl. According to an example, chloromethyl isoamyl ketone, ethylmagnesium halide, Me_3NH and $BzCl$, are the parent materials. The products are local anaesthetics.

Acetaldehyde. CONSORTIUM FÜR ELEKTROCHEM. IND. Brit., 16,957, July 17, 1914. In the manuf. of CH_3CHO by passing an excess of C_2H_2 through a hot soln. containing Hg compds., the conditions are so adjusted that a state of thermal equilibrium is attained or approx. attained; this is effected by adjusting the rate of flow of C_2H_2 and the temp. of the reaction vessel so that the heat evolved by the reaction is balanced by the heat lost by evapn. of H_2O , and by addition of fresh H_2O to keep the vol. of liquid const. The reaction may be performed in thermally insulated vessels, or in a vessel surrounded by a water-bath. A temp. of about 80° is suitable; H_2SO_4 of 6-35% strength is a suitable acid; HgO is periodically added, and the Hg formed removed.

Papaverine derivatives. A. PICTET. Brit., 17,578, July 24, 1914. Condensation products are obtained by treating tetrahydropapaverine or its derivs. with aliphatic or aromatic aldehydes, or with the corresponding acetals in presence of a mineral acid. According to examples, products are obtained from tetrahydropapaverine and methylal or acetal, and from aminotetrahydropapaverine and acetal. The aminotetrahydropapaverine is prepared by reducing nitrotetrahydropapaverine. The products have therapeutic properties.

Phenylcinchoninic acid. KALLE & Co. Brit., 17,725, July 27, 1914. 2-Phenylquinoline-4-carboxylic acid is prepd. by condensing isatin with acetophenone in the presence of aq. caustic alkali solns.

Nicotine from tobacco. F. T. BIRDWOOD. Brit., 17,024, July 17, 1914. In app. for extg. nicotine, NH_3 , etc., from tobacco, cigars, or cigarettes, by heating in receptacles in a chamber, the nicotine is condensed upon a conical surface and is run off from a trough by a pipe.

Tobacco. F. T. BIRDWOOD. *Brit.*, 17,265, July 21, 1914. Nicotine, etc., is removed from tobacco, cigars, cigarettes, etc., by subjecting them to the action of reduced pressure in a dry atm. with or without the aid of heat. The tobacco is placed in containers in a chamber connected to a condenser and exhaust pump and heated by a jacket supplied from a heater with hot air, which may pass in addition or alternatively through the said chamber to which air may be admitted.

2-Naphthylquinoline-4-carboxylic acids. CHEM. FABRIK AUF AKTIEN (v. E. SCHERING). *Ger.*, 284,232, June 19, 1914. Isatin or methylisatin in alk. soln. is condensed with acetonaphthones or their nucleus condensation products or aniline or its derivs. with naphthaldehydes or pyroracemic acid. The products are applied therapeutically.

Acyl compounds of anthranilic acid, its homologs and derivatives. F. HOFFMANN-LA ROCHE & Co. *Ger.*, 284,735, Sept. 2, 1913. Therapeutically active products result from the action of salicyl chloride on anthranilic acid, its homologs and derivs.

Strongly active stable technical pancreas preparations. LEPETIT, DOLLFUS & GANSSER. *Ger.*, 285,050, Aug. 5, 1913. Glycerol may be employed. Cf. *C. A.* 9, 724.

18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

T. LYNTON BRIGGS.

Chemical industry and academic education. OSKAR NAGEL. *Chem. Ztg.* 39, 749-50(1915). J. H. MOORE.

The university and industry. NICHOLAS M. BUTLER. *J. Ind. Eng. Chem.* 7, 1069-71(1915).—An address. E. J. C.

Evaporation of potash brines. W. B. HICKS. U. S. Geol. Survey, *Professional Paper* 95-E, 65-72(1915).—In literature on the evapn. of sea water and other natural waters there is a lack of data regarding K. The present expts. show the distribution of K when certain solns. are evapd. on the steam bath. For solns. containing KCl and NaCl, K_2CO_3 and Na_2CO_3 , K_2SO_4 and Na_2SO_4 the K/Na ratio after evapn. was 0.54, 0.67 and 0.58, resp., showing that the K was best concd. in the K_2CO_3 soln., but much of the K was crystd. from the soln. before this condition was reached. In more complicated mixtures containing several components, including $Na_2B_4O_7$, the amt. of K sepd. at different stages of the evapn. was detd. Apparently any soln. containing over 4% K begins to sep. K rapidly on further evapn., so that other processes than evapn. are to be recommended. R. C. WELLS.

New method for increasing potash supply. ANON. *Oil, Paint and Drug Rep.* 88, No. 19, 34(1915).—Brief description of a Canadian method in which feldspar is heated with limestone and Fe oxides. The partly fused mass is treated with dil. acid. E. W. BOUGHTON.

The present status and the future of the soda industry in Japan. TORAKICHI NISHIKAWA. *J. Chem. Ind. (Japan)* 18, 946(1915). E. H.

Canadian production of salt. FELIX S. S. JOHNSON. *Commerce Reports* 265, 602-3(1915).—Rock salt beds occur in the part of Ontario bordering on Lake Huron, the St. Clair River, Lake St. Clair and the Detroit River, an area of about 3000 sq. mi. The deposits vary in thickness from thin beds interstratified with dolomite and shale to solid beds of 200 ft. in thickness. The av. depth of the salt is more than 1000 ft. E. H.

Salt peter. A. MCGILL. Inland Revenue Dept., Ottawa, Canada, *Bull.* 323, 15 pp. (1915).—Analyses are given of 166 samples collected under the name of "salt peter." 109 were found to be KNO_3 , 49 were NaNO_3 , 7 were mixts. of KNO_3 and NaNO_3 and 1 was Na_2SO_4 . E. H.

Catalyst for the synthesis of ammonia. F. W. DE JAHN. U. S., 1,159,364, Nov. 9. Metallic Na is treated with NH_3 at about 300° and a catalyst is formed by distributing the resultant Na-N compd. over pumice, which has previously been washed with acid and H_2O and ignited, or other inert carrier. The Na may be melted on the pumice (before treatment with NH_3) in an atm. of H.

Catalyst for the synthesis of ammonia. F. W. DE JAHN. U. S., 1,159,365, Nov. 9. A mixt. of Co 59 and metallic Na 69 (or K 117) parts is treated with NH_3 at about 300° and the resultant Co-Na- (or K)-N compd. is used as a catalyst in making NH_3 from H and N at 520 – 540° under 80–90 atm. pressure. The Co may be reduced, from its nitrate, on the pumice. Catalysts containing (instead of Co) Mn, Ce, B, Ti, U or Si may also be used.

Pure alumina from clay containing iron. M. BUCHNER. U. S., 1,162,130, Nov. 30. Clay is treated with H_2SO_4 or other inorganic acid to dissolve both the Fe and Al and the soln. is treated with ammoniacal waste gases to ppt. hydroxides of Fe and Al and form a soln. of NH_4 salt. The ppt. is sepd. and the $\text{Al}(\text{OH})_3$ is dissolved with hot NaOH soln. and alumina and alkali are recovered from the soln.

Toughening crystalline fused aluminium oxide. L. B. COULTER. U. S., 1,161,620, Nov. 23. Granular fused Al_2O_3 is heated to about 1600 – 1800° to produce a stable physical equil. and greater resistance to crushing as well as more uniform diffusion of coloring matter throughout the grains.

Zirconium oxide. P. ASKENASY. U. S., 1,158,769, Nov. 2. A soln. of basic ZrCl_4 or other inorganic Zr salt containing Fe with or without other discoloring substance, is heated under pressure to a temp. above the b. p. of the soln. under atm. pressure and the ppt. is sepd. from the impurities, which remain in soln.

Alkali metal salts from kelp ashes. C. KLINGBIEL. U. S., 1,162,617, Nov. 30. A soln. leached from kelp ashes is treated with H_3PO_4 to destroy the thiosulfates present and the excess of H_3PO_4 is neutralized and K salts then may be more nearly all crystd. from the soln. than without the presence of phosphates.

Potassium sulfate. G. S. MORGAN. U. S., 1,161,239, Nov. 23. Alunite is roasted with CaO at a temp. of 650 – 930° , the roasted product is leached, the soln. concd. and K_2SO_4 recovered by crystn.

Recovering potash from greensand marl. H. P. BASSETT. U. S., 1,159,464, Nov. 9. Greensand marl consisting principally of glauconite is washed and screened to remove lighter particles and relatively large particles of quartz, etc., and the concentrates after drying are mixed with NaHSO_4 and NaCl and heated with coke to a dull red heat for 20–40 min. or without coke for 1–3 hrs. The coke is used in sufficient amt. to reduce only a portion of the NaHSO_4 to sulfide. The reaction products are treated with H_2O to recover the K_2SO_4 and other sol. substances formed.

Manufacture of zeolites. P. DE BRÜNN. U. S., 1,161,200, Nov. 23. Solns. of alkali metal silicates and aluminates are mixed and the resulting jelly- or paste-like ppt. is washed, filter-pressed and the press-cake dried. Cf. C. A. 9, 2573.

Nitrogen compounds of aluminium and alkali or alkaline earth metals. D. A. PENIAKOFF. U. S., 1,159,989, Nov. 9. Porous masses formed by agglomerating a mixt. of coal and an alk. earth or alkali metal aluminate are heated in a current of N to produce cyanides or other volatilizable N compds.

Adhesive mixture. J. W. and R. SCHLEICHER. U. S., 1,162,712, Nov. 30. Talc 1 and 3.6° Bé. soln. of water-glass 16 parts are mixed, forming an adhesive for use either hot or cold for making veneer boxes, etc.

Ink for printing on cloth. C. J. BULLINGER. U. S., 1,162,027, Nov. 30. A harmless ink, for printing on cloth, which is easily removable by brushing or by washing with H_2O but resistant to hydrocarbons, is formed of gelatin glue 1, H_2O 76, Zn white 52, glycerol 3 oz., and thymol 16 grams.

Fire-extinguishing composition. W. W. WALKER. U. S., 1,161,090, Nov. 23. A foam retaining and fume deterring ingredient for use in fire-extinguishing compns. is formed by boiling "spent licorice root" (obtained as a residue from the extrn. of licorice root with H_2O) with NaOH soln. under 120 lbs. per sq. in. pressure.

Sharpening worn files chemically. A. J. ZIRSEN. U. S., 1,161,816, Nov. 23. Worn files are covered with H_2O and then fuming H_2SO_4 and HNO_3 are added to the bath to heat it and act on the files.

Molding varicolored casein masses. F. THOMAS. U. S., 1,159,878, Nov. 9. Varicolored spherical casein masses are formed by allowing several differently colored streams of alkali caseinate to fall vertically in the form of drops, to a common point in a soln. containing CH_2O and $CaCl_2$ or other alk. earth salt. The casein solns. used may have different viscosities, to prevent too great blending. The varicolored particles thus obtained are used to imitate horn, etc.

Small casein spheres. F. THOMAS. U. S., 1,159,879, Nov. 9. Separate cells or chambers open at their upper ends are formed within a body of coagulating soln., formed, e. g., of $MgCl_2$ or $CaCl_2$ and CH_2O , and streams of alkali caseinate soln. are allowed to flow freely into each of the cells. This produces spherical masses of coagulated casein which are then sepd. from the remaining coagulating liquid. Rough blanks for buttons, beads, etc. are thus obtained.

Lithographic printing plates. J. JAMES. U. S., 1,162,168, Nov. 30. The impression paper is pressed on the plate and the paper soaked off, the plate then coated with a soln. of gum arabic, rubbed with ink, dusted with talcum powder, etched with an acid soln. containing gum arabic, again coated with gum arabic, dried, washed with turpentine, coated with an asphalt soln. in turpentine and after testing is finally coated with a mixt. of kauri gum, turpentine and Chinese oil and again etched.

Electric insulating composition. J. F. MENNINGEN. U. S., 1,162,092, Nov. 30. A mixt. of sand 5, asbestos 3 and shellac 4 parts with a solvent is molded under pressure while heated, then heated without pressure to volatilize the solvent of the shellac and finally again heated under pressure to compact the somewhat shrunken article. Cf. C. A. 9, 179.

Electrical insulation. L. H. BAEKKELAND. U. S., 1,160,362, Nov. 16. Paper pulp is beaten with a phenolic condensation product capable of transformation into infusible form by heating, and after thorough mixing is effected the product is pressed into the desired form and heated sufficiently to render it infusible. 15-50% of condensation product is preferably used. Knife handles, buttons, etc., may also be made of the compn.

Paper-like phenolic condensation mixture, for use in making molded articles. L. H. BAEKKELAND. U. S., 1,160,365, Nov. 16. Wet paper pulp is treated with a soln. of phenolic condensation product (transformable into insol. form by heating) containing alkali metal hydroxide and the condensation product is then pptd. on the fiber by the addition of a sol. salt of Al, Cu, Fe, Zn, Ni, or Co. China clay or other fillers may be added.

Gears, pulleys, etc., from phenol condensation products. L. H. BARKLAND. U. S., 1,160,364, Nov. 16. Perforated sheet metal reinforcing plates are united by a body material of hard, insol., infusible phenolic condensation product, mixed with wood fiber, asbestos or other fibrous filler, which penetrates the perforations of the sheet metal and forms the principle portion of the gear or wheel. 10% of graphite may be included in gears as a lubricant.

Heat insulating material. C. P. BYRNES. U. S., 1,162,450, Nov. 30. Air is injected into a mixt. of cork with a binder of asphalt, or other similar heat-insulating material, before it has hardened, to increase the porosity of the final mixt. by providing air cells in it additional to those naturally present in the cork or other porous filler.

Friction-lining for brakes, etc. E. F. KELLEY. U. S., 1,162,371, Nov. 30. A brake-lining fabric of asbestos is impregnated with a soln. formed by dissolving $MgSO_4$ and alum in a hot decoction of ground bone and beer vinegar.

Artificial gold leaf. J. A. C. FICHTMUELLER. U. S., 1,160,979, Nov. 16. Leaves are formed of a pyroxylin varnish carrying naphthalene yellow or auramine and Al powder, dried upon a sized paper backing so as to permit partial stratification of the yellow coloring at the face of the leaf.

Fuller's earth for decolorizing oils. M. J. WELSH. U. S., 1,159,450, Nov. 9. Raw fuller's earth is treated with hot acid, *e. g.*, HCl, to dissolve alk. earth compds. and other impurities tending to fuse or sinter during calcining, then washed to remove the sol. substances and calcined. Cf. C. A. 9, 1257.

Lubricant for packing stuffing boxes. A. J. BAILEY. U. S., 1,158,770, Nov. 2. Pulverized white metal 112 parts is mixed with talc 4, graphite 6, tallow or other fat 6, carded asbestos 4 and pulverized cork 2 parts.

Decarbonizing internal-combustion engines. W. E. AHERN. U. S., 1,160,682, Nov. 16. The C deposits in the engine, while hot, are treated with cold 20% NH_3 soln. which is further refrigerated by the resulting vaporization and effects cooling, contraction and disintegration of the C.

Depositing carbon in the pores of wood and other porous materials. W. A. BEATTY. U. S., 1,158,965, Nov. 2. Wood, paper or other porous substance to be impregnated and colored by deposition of C in its pores is impregnated with a soln. of sugar, H_2O , turpentine and H_2SO_4 and then heated with steam under a pressure of 75-100 lbs. per sq. in. to hasten the deposition of C. Leather may be treated similarly, using CrO_3 , $K_2Cr_2O_7$ or $ZnCl_2$ instead of H_2SO_4 .

Composition for filling cavities in trees. C. H. ERWIN. U. S., 1,160,701, Nov. 16. A mixt. is formed of ground asbestos 40, refined coal tar 50, pine oil 8 and a pigment (such as to match the bark of the tree to be filled) 2%.

Gramophone records. W. A. BEATTY. U. S., 1,158,964, Nov. 2. Fillers such as graphite, wood powder, steel dust, lampblack or Fe_2O_3 are mixed with a condensation product of acetone, PhOH and CH_2O and records are molded of this mixt.

Phonograph records. T. A. EDISON. U. S., 1,158,659, Nov. 2. A mixt. of diphenylamine 15, shellac 70 and acetanilide 2 parts is used for forming the records.

Phonograph records. T. A. EDISON. U. S., 1,158,660, Nov. 2. The records are formed of an emulsified mixt. of shellac with about 35% its wt. of stearic acid or an emulsion of shellac with $C_{10}H_8$ and benzoic acid. A camphor-shellac mixt. is too readily deformable by heat to give as durable a record.

"Artificial snow" for christmas trees, etc. B. W. HEYMAN. U. S., 1,162,060, Nov. 30. A mixt. of soap 2 and glycerol 1 part, with ground mica and H_2O is used.

Calcium hypochlorite. CHEM. FABRIK GRIESHEIM-ELEKTRON. Brit., 17,859, July 28, 1914. $\text{Ca}(\text{OCl})_2$ is obtained by treating a pulp of lime and H_2O containing comparatively little H_2O with Cl , the quantity of H_2O being preferably such that only the $\text{Ca}(\text{OCl})_2$ is pptd., the CaCl_2 remaining in soln.; the soln. is sepd., and the $\text{Ca}(\text{OCl})_2$ may be freed from H_2O of crystn. by drying *in vacuo*. In carrying out the process, the Cl is passed into a pressure vessel containing the lime pulp, which is kept stirred, and the temp. is chosen to avoid the production of basic intermediate products. Cf. C. A. 9, 2436.

Magnesium carbonate. A. HAMBLOCH. Brit., 17,311, July 21, 1914. Raw or roasted minerals containing Mg and Ca as carbonates or silicates, are treated with a soln. of alkali carbonate or bicarbonate and CO_2 under pressure at $60\text{--}70^\circ$. The liquor is filtered, CaCO_3 remaining behind, while from the soln. of Mg alkali carbonate, MgCO_3 is pptd. by heating to 100° , and the soln. of alkali carbonate and the evolved CO_2 may be used again. Cf. C. A. 9, 1536.

Double silicates. W. E. EVANS and E. L. LEBLANC. Brit., 17,663, July 25, 1914. In the production of base-exchanging bodies by the wet method from Na aluminate and Na silicate, the reaction is carried out under pressure in an autoclave. A hard granular ppt. is obtained which is suitable for use without further treatment. The autoclave may be provided with a filter-plate at the bottom. The reagents may be mixed before being placed in the autoclave, the concn. in this case being such as to render pptn. under ordinary conditions difficult or impossible. The proportions mentioned in 15,090, 1913, may be used, but the concns. may advantageously be reduced. Particles of an inert substance, such as coke or wood, may be maintained in suspension to serve as centers upon which pptn. may take place.

Removing iron from aluminium silicates, kaolin, clay, etc. F. SCHULZ, AKT.-GES. and H. GRUBER. Brit., 2,309, Jan. 28, 1914. These and other inert materials such as BaSO_4 , fluorspar, cryolite, Zr earth, and sand, are treated with a soln. of an aldehydesulfoxylic acid, or a ketone-sulfoxylic acid, or a deriv. thereof, in the presence of a mineral acid, the other inert materials above mentioned being treated with a soln. of hyposulfurous acid (hydrosulfurous acid) or a salt thereof in the presence of a mineral acid. Sand, fluorspar, and cryolite, thus purified, are suitable for making glass, Zr earth for making incandescent gas mantles, and BaSO_4 as a pigment.

Hydrogen. J. DEMPSTER. Brit., 16,893, July 16, 1914. In app. for the production of H by the alternate oxidation of Fe or the like by means of steam and reduction of the oxide by means of water gas or other reducing gas, leakage of water gas into the H connections is prevented by providing a liquid seal between the H outlet pipe and the H scrubber, the seal being also in connection with the water gas inlet main, so that increased pressure in the water gas inlet main increases the depth of seal of the H outlet pipe.

Iron oxide and like castings. SOC. ITALIANA DI ELETTROCHIMICA. Brit., 17,161, July 20, 1914. Fe oxide castings in which the ratio of Fe_2O_3 to FeO is greater than 3, and may reach pure Fe_2O_3 , are obtained by fusing an Fe oxide (which may be a crude oxide such as burnt pyrites) or metallic Fe in an elec. furnace and injecting into the mass in the furnace or in a converter, O or an oxidizing gas, or adding an oxidizing agent with stirring, the treatment being effected under pressure, and casting in an oxidizing atm. Mixts. of Fe oxide with other oxides, such as oxides of Mn , W , Ti , Cr , V , Co , Ni , Mo , and U , may be similarly treated. The castings may be vessels, pavements, coatings, etc., and articles for elec. use such as arc-lamp electrodes and anodes and cathodes for electro-chem. purposes.

Plastic compositions. K. HAGENDORF and A. BRESLAUER. Brit., 17,728, July 27, 1914. HCOOH and "trioxymethyl" or HCHO are added to bovine blood serum and the resulting mass heated with phenol and Na_2O_2 until it becomes hard. In an example, 100 parts of blood serum are mixed with 25 parts of HCOOH and 20-30 parts of "trioxymethyl," and 80-90 parts of phenol and Na_2O_2 in H_2O are then added until the mixt. becomes alk.; finally, 10 parts of Na_2SO_3 are added to the mass which is heated and poured into molds when it is again heated until it hardens. The use of albumins other than blood serum and of H_2O_2 instead of Na_2O_2 is mentioned.

Plastic compositions; linoleum; explosives. L. ZINSSER. Brit., 17,413, July 22, 1914. Ground earth-nut shells are used as an absorptive or filling material in the manuf. of linoleum, stone-wood flooring and the like, and dynamite.

Joint-making compositions. W. H. WALKER. Brit., 17,686, July 27, 1914. A compn. consisting of 60-80 parts of prepared chalk, 10-30 parts of vaseline, 1-5 parts of castor oil, and 1-5 parts of Fe_2O_3 paint, is employed for making water-tight the joints of covers of boxes for underground elec. mains and distributors and of other boxes in exposed positions.

Lubricant. S. H. BLICHFELDT. Brit., 15,463, June 27, 1914. It consists of an emulsion of relatively insol. liquids, 1 of which has comparatively low internal friction, the diam. of the suspended particles being 0.001 mm. or less. Emulsions of oil or fat in H_2O , in aq. solns. as of soap, or, where evapn. may be rapid, in glycerol or an aq. soln. of glycerol, are typical. Suitable emulsifying-app. is described in 7,498, 1912 (C. A. 7, 2999), 23,653, 1913 (C. A. 9, 943), 25,265, 1913 (C. A. 9, 1229) and 18,048, 1914.

Filtering colloidal solutions. J. VON KRUSZEWSKI. Brit., 17,503, July 23, 1914. Colloidal solns. are filtered by means of a number of superposed sieves, 1 or more of which is prevented from being wetted by the filtrate, by being smeared, as with a thin film of fat, oil, wax, paraffin, or the like. In the case of sludge containing fat, it is unnecessary to apply a special film to the sieves. Alternatively to greasing the sieves, two finely-meshed sieves may be secured together by soldering, riveting, or screwing, so as to cause them to be sepd. by capillary distances at as many points as possible. The greater part of the liquid passes through in a clear condition, and the less viscid part of the residue may be forced through by vacuum, or it may be sucked off from the top of the pptd. cake without filtration. The sieves are preferably arranged in the form of chambers to give the max. filtering surface in a given space.

Drying and superheating steam. G. RESTUCCI. Brit., 15,104, June 23, 1914. Steam is throttled in 1 or several sets of nozzles, each nozzle being formed with a convergent passage which merges into a slightly divergent passage at the small end; the axes of the nozzles are arranged approx. in the direction of flow of the steam.

Liquid for filling radiators. H. FRANK. Brit., 24,827, Oct. 31, 1913. A volatile liquid or solid of low sp. heat is mixed with a non-volatile liquid of high sp. heat to produce a mixt. of low sp. heat which can be heated without appreciable vaporization, the invention being thus distinguished from 20,241, 1911, 29,590, 1912, and 1,204, 1913. Mixts. of oil with trichloroethylene and hexachloroethane are described as suitable for the purpose of the invention.

Fire-extinguishing. J. STANZIG and R. KÖNIG. Brit., 16,967, July 17, 1914. In producing foam for fire-extinguishing by dissolving solid reagents, H_2O under pressure is conducted successively through 2 chambers, 1 containing the acid charge, in the form of powdered oxalic or tartaric acid, *e. g.*, and the other the alk. charge, consisting, *e. g.*, of powdered NaHCO_3 , quillaia bark, a saponin or other foam-forming substance, and in some cases an NH_4 or alk. alum.

Sensitized tracing cloth. R. A. RITSCHARD. Brit., 17,640, July 25, 1914. A transparent sensitized tracing-cloth is made by coating one side of ordinary tracing-cloth with an oil varnish or lacquer to render it waterproof and then applying to the other side of the cloth a sensitized coating of any known kind, such as Fe NH_4 citrate and $\text{K}_2\text{Fe}(\text{CN})_6$ with gelatin. The copies obtained are developed in H_2O mixed with chrome-alum, formalin, or other gelatin-hardening agent.

Drying the end lyes of the potash and soda manufacture. B. RINCK. Ger., 284,970, Sept. 7, 1912. An evapg. app. is used which comprizes a hollow cylinder into which the hot combustion gases and the end lyes are directed in the same direction.

Regulating the temperature of superheated steam. C. KOSE. Ger., 284,818, Apr. 5, 1914. The control is secured by both cooling and the addition of satd. steam.

Coloring stones with metal salt solutions. CANOVA-MARMOR-WERKSTATTEN. Ger., 284,689, Nov. 12, 1913. Polyhydric alcs., also phenols, aldehydes, ketones, or carbohydrates, are added to the alc. soln. of the metal salts, in amt. not over 50% of the solvent.

Stain removing composition. OCKELMANNSCHE SEIFEN-VERWERTUNGS G. M. B. H. Ger., 284,974, Oct. 11, 1913. Addition to 259,360 (C. A. 7, 3000). The principal process, according to which sugar is added to permit the use of a large amt. of alkali and thereby secure a more effective cleaning and detergent action, is applied in the production of a solid spot-removing, washing, or bleaching agent. The amt. of H_2O used is decreased, and the amt. of added sugar is greatly increased. The amt. of alc. added must be somewhat smaller in prepg. the solid form. E. g., 4% KOH, 80-83% sugar, 12-14% alc., or NaOH 3%, sugar 84-87%, and alc. 12%.

Impregnating belting with asphalt. AKTIESELSKABET ROULUNDS FABRIKER. Ger., 285,049, Nov. 4, 1913. After satn. with an asphalt soln., the material is treated with a soln. of balata, gutta percha, or like gum. The asphalt soln. may be used together with the soln. of balata or the like. The woven belting, or the like, is passed through a 10% benzene soln. of asphalt, and allowed to dry. This is repeated until the impregnated belting shows no further alteration in length. The material is then drawn through a soln. of balata or the like, and subjected to strong pressure.

Preventing oxidation of atomized liquid or vaporized metals. G. STOLLE. Ger., 284,911, Aug. 12, 1913.

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

Relation of chemistry and mechanical manipulation to the evolution of the glass industry. R. L. FRINK. *Met. Chem. Eng.* 13, 800-2(1915).—Historical.

C. H. KERR.

Enamel and its use in the chemical industry. J. SCHAEFER. *Z. angew. Chem.* 28, I, 419-20(1915).—History of the industry and a general description of enamels and enamelling methods.

C. H. KERR.

The subdivision of stoneware glazes into fritted and raw parts and their relation to glaze rules. H. HARKORT. *Z. angew. Chem.* 28, I, 422-8(1915).—In stoneware glazes not only the total mol. formula but the subdivision into raw and fritted parts must be considered. It has been common practice to frit a large part and sometimes all of the glaze and usually the effect of fritting has been ignored. This is erroneous since fritting exerts a great influence, so great that in some cases 2 glazes of the same chem.

formula but of different fritted compn. may show one to be useless and the other commercial. Harkort exptd. with 11 glazes of widely differing compns. (4 without PbO). The range of compn. was: CaO 0.54 to 0.29, Na₂O 0.50 to 0.01, K₂O 0.20 to 0.08, PbO 0.33 to 0, Al₂O₃ 0.35 to 0.20, SiO₂ 2.65 to 2.08, B₂O₃ 0.43 to 0.36 equiv. Studying the glazes at temps. from cones 01 to 6 the temp. effect was very great. With leadless glazes, especially those high in CaO, bubbles were hard to avoid. In general 0.4 equiv. CaO is the max. permissible with glazes of 2.5 or over of SiO₂, and CaO must be decreased if acidity decreases. B₂O₃ volatilizes easily, especially under the influence of SO₂ from furnace gases. With glazes of less than 2.5 equivs. SiO₂ and with 0.4 to 0.5 CaO the surface was a dull mat and in some cases the glaze was entirely destroyed. With more SiO₂ and less CaO the effect diminished. The presence of CaCO₃ in the raw addition affords protection against the attack of H₂SO₄. With PbO used only in the frit a much higher temp. is required to produce the same effect than is required if part of PbO is used raw. PbO in the raw addition exerts no influence on the volatilizability of B₂O₃. (Note by abstractor: In Germany the term "stoneware" includes higher grades of ware than in the U. S.) C. H. KERR.

Report of Committee C-3 on standard specifications for brick. A. V. BLEININGER, *et al.* *Proc. Am. Soc. Testing Materials* 15, Pt. 1, 150-9; appendix 160-2 (1915); cf. C. A. 9, 958.—*Building Brick*: Tabulated reports are given from 12 cooperating labs. testing compressive and transverse strength and absorption of representative bricks in their districts. Wide fluctuations in absorption made classification by those data impossible. They were classified according to compressive strength as follows: A, having a compressive strength of 5000 lbs. per sq. in. or more; B, 3500-5000 lbs.; C, 2000-3500 lbs.; D, 1500-2000 lbs. The av. compressive strength (lbs. per sq. in.), modulus of rupture (lbs. per sq. in.) and % absorption, resp., for the 4 classes were: A 8493, 1482, 9.82; B 4171, 668, 15.76; C 2791, 621, 18.97; D 1762, 469, 19.17. Compressive testing of bricks on edge is much preferable. A freezing test or suitable substitute should be investigated. *Paving Brick*: Standard specifications have been adopted. See 1915 Year Book of the Society. C. H. KERR.

Magnesite deposits in British Columbia. ANON. *Brit. Clayworker* 24, 134 (1915).—The ore found in large quantities along Lake Atlin in N. E. British Columbia has been tried with success. It runs as high as 98% MgCO₃. C. H. KERR.

Diatomite from Nova Scotia. ANON. *Brit. Clayworker* 24, 134-5 (1915).—The Nova Scotia product has good sp. gr. and other properties except its grayish color. The analysis is given. C. H. KERR.

The influence of bituminous matter in brick clays. ANON. *Brit. Clayworker* 24, 143-4 (1915).—Details are given of methods of regulating the air supply during burning. C. H. KERR.

Vitreous enamels or glazes for pottery, etc. S. H. HULL. U. S., 1,158,922, Nov. 2. Metallic Pb is used as a substitute for white lead in making up the glazing compns. to effect a saving in wt. and cost of the Pb required. The Pb is used in about the same state of fine subdivision as that of white lead previously similarly employed.

Refractory furnace linings, crucibles, etc. A. PFAFF. U. S., 1,159,264, Nov. 2. A homogeneous, dense and tough material for manuf. of crucibles, furnace linings, etc., is prepd. by mixing zirconia with about an equal amt. of somewhat coarser-grained carborundum, molding and burning.

Lining for basic open hearth furnaces. A. P. MEYER. U. S., 1,160,085, Nov. 9. Granulated dolomitic limestone is calcined and then heated to its sintering temp.,

cooled and mixed with sufficient granulated basic open hearth slag to fill the voids in the sintered material and act as a binder.

Heat-insulation for steam pipes, etc. B. J. CHRISTIE. U. S., 1,161,289, Nov. 23. Flax straw 1 and fire clay 16 parts are mixed with H_2O and with a binder formed of H_2O impregnated with Fe rust, vinegar, borax, glue and linseed oil.

Bricks. G. HIMOUX and J. BERNHEIM. Brit., 17,876, July 28, 1914. Pulverized clay, etc., for the manuf. of floor and roofing tiles, bricks, etc., after being prepd. by disaggregation and artificially dried, is pulverized, then sifted, and subsequently moistened by a fine spray, the mass being then compressed at high pressure in greased and closed molds.

Glass blowing machines. TREUHAND-VEREINIGUNG, AKT.-GES. Ger., 284,517, Nov. 26, 1912.

Process and apparatus for manufacturing earthenware vessels. MEISSENER OFEN- UND PORZELLANFABRIK V. E. TEICHERT. Ger., 284,722, Mar. 10, 1914. Addition to 282,773 (C. A. 9, 2579).

Surface-combustion plates. O. KNÖFLER & Co. Ger., 284,395, Feb. 21, 1914. Porous refractory masses which do not sinter in use are manufactured with the employment of ZrO_2 or of substances containing this oxide. The desired shape can be given to the plates by pressing or molding according as a greater refractory character and less porosity, or less refractory and greater porous properties are desired. When casting the ZrO_2 mass a binder is used which is driven off upon ignition, thereby securing greater porosity. The presence of TiO_2 is advantageous.

Alkali-containing clouding agent for white enamel. VEREINIGTE CHEM. FABRIKEN LANDAU, KREIDL, HELLER & Co. Ger., 283,792, Aug. 24, 1912. Metal compds., other than those of Sn, which are suitable for the purpose, are used. Cf. C. A. 9, 363.

Automatic cutting device for brick bar presses. J. OTTERPOHL. Ger., 284,337, May 2, 1914.

Automatic brick cutting machine. H. WEIHE. Ger., 284,723, Apr. 11, 1913.

Operation of automatic brick cutting machine. H. WEIHE. Ger., 284,724, Nov. 9, 1913.

Discharging pressed bricks. C. LUCKE. Ger., 284,760, May 25, 1913.

Stacking fresh bricks for drying. P. DÖRING. Ger., 284,306, July 11, 1913.

20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

The function of ferric oxide in the formation of portland cement clinker. E. D. CAMPBELL. *J. Ind. Eng. Chem.* 7, 835-7(1915).—A series of expts. indicates that " Fe_2O_3 is molecularly equiv. to Al_2O_3 so far as formation of celite goes."

C. N. WILEY.

Tests of Oregon fir piling. H. B. MACFARLAND, Eng. of tests, A. T. and S. F. Ry. System. *Am. Ry. Eng. Assoc.* 16, Part 2, 47-150(1915); cf. C. A. 9, 140.—Twenty pieces of Douglas fir piling were creosoted by the steaming process, using a max. steam pressure of about 90 lbs. Ten were steamed 3 hrs. and ten 9 hrs., followed by a long vacuum period and the injection of creosote under max. pressures of 114 lbs. and 125 lbs., resp. Twenty similar pieces were tested untreated. Details of treatments and methods used in subsequent strength tests are given together with numerous photographs, tables and diagrams. McF. concludes that the depth of penetration of

the oil was mainly dependent on the width of the sapwood; the treatments used decreased the strength approx. $\frac{1}{2}$; the injury to the fiber extended through both the heartwood and sapwood; and the more severe treatment caused the greater reduction in strength.

GEO. M. HUNT.

Application of the Davis spot test in preliminary examination of creosotes (CLOUKEY) 22. Concrete shoes 29.

Alkali and cement from feldspar and similar minerals. A. W. HEYMAN. U. S., 1,160,171, Nov. 16. The minerals, preferably feldspar, granite, mica or clay, are heated to about 900–1600° with CaCO_3 , CaSO_4 or marl in such proportions as to give a CaO content of 1.7–2.2 times the wt. of the argillaceous material in the product. The alkali hydroxide formed is recovered by lixiviation with H_2O and the residue is converted into cement by calcining and grinding.

Alkali and cement from feldspar or similar minerals. A. W. HEYMAN. U. S., 1,160,172, Nov. 16. After heating the minerals, *e. g.*, feldspar, clay, mica or slate, to about 900–1600° with marl or CaCO_3 (without addition of chlorides) the product is lixiviated with H_2O and CO_2 is passed through the soln. obtained. The residue is converted into cement by calcining and grinding.

Waterproofing cement or plaster articles. L. H. BAEKELAND. U. S., 1,160,363, Nov. 16. Hydrated cement or plaster tiles, etc., are coated with a phenolic condensation product and heated to 160–200° under 80 lbs. per sq. in. pressure. Elec. insulators may be made of plaster of Paris, asbestos, MgO and phenol condensation product.

Finishing plastered wall surfaces. C. M. GOULOCHER and J. N. STACY. U. S., 1,160,708, Nov. 16. The wall is first washed with a 25% soln. of KNO_3 , then treated with a soln. of alum and allowed to dry, sandpapered to a smooth finish, sized and finally dusted with sawdust, ground asbestos, mica or other finely powdered finishing material before the sizing has dried.

Coloring stone. L. SCHRATT. U. S., 1,158,730, Nov. 2. A mixt. for penetrating and coloring the surface of marble, granite, etc., is formed of tar 40, salicylic acid 10, Na_2CO_3 10, NaHCO_3 10, SCl_2 2, Mg 5 and MeOH 10 parts, heated to the b. p. with 100 parts of H_2O , filtered and mixed with a pigment.

Fire-resistant building board. R. A. PLUMB and C. R. WEGD. U. S., 1,159,866, Nov. 9. A layer of loose asbestos fibers mixed with H_2O is placed on one or both surfaces of a sheet of pasty mixt. of hydraulic cement and H_2O and the composite sheet thus formed is pressed and heated to 100° to effect a firm union between the fibers at the surface and the main body of the mass.

Composition for rendering wood resistant to water and fire. S. R. CHURCH. U. S., 1,162,453, Nov. 30. Hexachloronaphthalene or other waxy chlorinated naphthalene is mixed with about 25–40% its wt. of wax tailings and a volatile solvent such as coal-tar naphtha and the mixt. is used to impregnate shingles or other wood products.

Cement. E. LONGAN Y SENAN. Brit., 17,756, July 27, 1914. The free lime present in cements or hydraulic limes is caused to react with a suitable proportion of granite or diorite which has been heated for at least 2 hrs. at about 1000° and afterwards finely powdered. A concrete may be made from the cement thus produced by adding calcined fragments of granite or diorite of the same nature as that used in the prepn. of the cement or hydraulic lime. A suitable furnace is specified.

Cements. E. MÜLLER and E. EICHERT. Brit., 17,829, July 28, 1914. Magnesian cement is made by powdering together burnt magnesite and dry, unburnt clay

Determination of nitrogen in coal. A comparison of various modifications of the Kjeldahl method with the Dumas method. ARNO C. FIELDNER AND CARL A. TAYLOR. *Bur. of Mines, Tech. Paper 64*, 25 pp.(1915).—Of the several modifications of the Kjeldahl method applied to 8 coals with N contents ranging from 0.8 to 1.8%, the combined Kjeldahl-Gunning with the use of 0.7 g. Hg, 7.0 g. K_2SO_4 and 30 cc. H_2SO_4 proved the best, giving max. values for N with minimum digestion. The addition of $KMnO_4$ in the usual way shortened the time necessary for oxidation and in no case did it cause a loss of N; in all detns. it was necessary to continue the digestion 2 hrs. after the solns. became colorless. Modifications for nitrates or nitro compds. are unnecessary. Check detns. by the Dumas method to establish the accuracy of the Kjeldahl-Gunning showed max. variations in av. values of 0.10%, with mean differences of 0.05%. H. L. O.

A new method and furnace for the determination of the softening temperature of coal ash under fuel-bed conditions. A. C. FIELDNER AND A. L. FIELDS. *J. Ind. Eng. Chem.* 7, 829-35(1915).—The state of oxidation of the Fe in ash greatly influences the fusibility of the ash; hence the nature of the atm. in which the fusion tests are made is very important. Ashes fuse at a much higher temp. in an oxidizing atm. than in a reducing atm. A 50% mixt. of H_2 and H_2O leaves the iron in ashes in the same state of oxidation as the $CO-CO_2$ atm. actually present in a fire bed; F. and F. use the former atm. in the lab. fusion tests. An app. (furnace and saturator) is shown which involves electrical heating with Mo wire in a H_2-H_2O atm., which prevents oxidation of Mo at 1400° . The softening temps. of 19 ash samples in the H_2-H_2O atm. as detd. in the above app. are given. F. L. GROVER.

A new peat distillation process. ANON. *Elec. Rev. West. Elec.* 67, 994(1915).—The peat is broken up in a macerator, compressed into briquets, dried to reduce moisture to 25% and fed by means of a worm screw conveyer through a triple chamber retort in which the successive chambers have increasing temps. The gases are condensed and the condensate separated. Coke, fuel, oil, toluene, ammonia, paraffin wax and acetone are obtained. Z. SMILOVICI.

Wet distillation of fuels. E. H. STECK. *Feuerungstechnik* 3, 293-4(1915).—S. discusses a new method (distn. with steam) of distg. coal whereby the yield of by-products is greatly increased. Dry distn. of bituminous coal yields on an average 11 to 16% of the org. N as $(NH_4)_2SO_4$ and only 5% of the org. matter of the coal as tar; on the other hand, wet distn. of bituminous coal yields as much as 85% of the org. N as $(NH_4)_2SO_4$ and 10% tar. The most suitable temp. for the formation of NH_3 in dry distn. of coal lies between 350 and 800 and for lignite between 200 and 600°, while with the wet distn. the decompn. of the NH_3 does not take place until temps. above 1000° are reached. The chief importance of the new method lies in the fact that it cheapens the cost of distn. and increases the yield of by-products, making the value of the by-products much more valuable than the raw fuel. H. R. GUNDLACH.

Gaseous combustion. W. A. BONE. *Chem. News* 112, 211-7, 223-5(1915).—Presidential address. A review of the recent work of Dixon, Coward and Wheeler upon ignition phenomena, propagation of flames through inflammable mixts., and limits of inflammability. F. L. GROVER.

Examination of a condensate from carbureted water gas. E. T. STERNE. *J. Ind. Eng. Chem.* 7, 898-9.—An analysis of the condensate in the service pipes of a certain gas works showed 75.88% paraffins, 1.62% olefins and 22.5% aromatic. About 12% was commercial benzene distg. between 78 and 82°, while 10% was commercial toluene distg. between 108-112°. S. notes that the production of toluene during the manuf. of carbureted water gas is not unreasonable. F. L. GROVER.

Analysis of natural and illuminating gas by fractional distillation at low temperatures and pressures. G. A. BURRELL, F. M. SEIBERT AND I. W. ROBERTSON. Bureau of Mines, *Tech. Paper* 104, 38 pp.(1915).—This paper describes a method of sepn. the paraffin hydrocarbons in natural or illuminating gas, which depends upon the differences in b. ps. of the various constituents. With natural gas, CH_4 is removed at the temp. of liquid air; ethane is removed from propane and butane at -150° to -140° ; propane is pumped off at -135° to -120° . This is the only known method of sepn. of these gases. With illuminating gas, CH_4 , H_2 , CO , N_2 and O_2 are removed at the temp. of liquid air; ethane and ethylene below -140° ; and propane and propylene below -120° . Benzene is sepd. from the residue of benzene, butylene, and butane at -78° . Ethane and ethylene cannot be sepd. from each other because their b. ps. are too close together.

F. L. GROVER.

The maximum content of hydrocarbons in generator gas. F. HOFFMANN. *Feuerungstechnik* 3, 269-72, 285-8, 295-7(1915).—An attempt has been made to calc., on the basis of the compn. of gas obtained from the dry distn. of the same coal, the possible limits of the content of hydrocarbons in generator gas. The hydrocarbons considered are methane and the heavy hydrocarbons (ethylene, propylene, benzene, etc.). If the yield of hydrocarbons per unit of wt. of coal would be the same if distd. from a retort as from a generator, it can be calcd. that the yield of heavy hydrocarbons from a German gas coal must be approx. 0.25%, and the methane yield approx. 2.4%. Since the conditions for hydrocarbon formation are more unsuitable in a generator than in a retort the actual contents are approx. $\frac{1}{3}$ the above amts. Considered from a purely volumetric standpoint the hydrocarbon content remains the same whether steam is used in the generator or not. Introduction of steam, however, lowers the temp. of the reaction zone and the methane content probably becomes less with increased steam introduction, the content of heavy hydrocarbons also being decreased.

H. R. GUNDLACH.

Calorific value test in Canada. ANON. *Gas World* 63, 353-54(1915).—By a Canadian Act of 1910 the Governor in Council was given authority to make regulations for testing the calorific value of gas. This test has now been substituted for the illuminating power test throughout the whole of Canada. It is applicable to both artificial and natural gas. By the regulations made under the Act the B. t. u. is adopted. The standard cal. power of the gas supplied shall be 520 B. t. u. per cu. ft. of satd. gas when burned in satd. air and the vol. of gas corrected for a temp. of 60° F. and a pressure balanced by a column of 30 in. of Hg at the same temp. The Canadian authorities have adopted the Simmance & Abady total-heat calorimeter made by Messrs. Alexander Wright & Co., Ltd., of Westminster as the official instrument. This calorimeter insures automatically that constancy or balance of vols., temps. and humidity, the existence of which makes the use of any formula or correction quite unnecessary, and it, therefore, under all conditions, automatically indicates the total heat value. An illustration of the calorimeter is shown.

M. L. TROWBRIDGE.

Producer gas power plants in New York City and the Metropolitan district. C. M. RIPLEY. *Power* 42, 808(1915).—Operating data and costs are tabulated. The opinions of plant owners indicate that most of the plants, particularly the smaller ones, are giving satisfaction.

C. G. F.

Certain preliminary experiments on the utilization of peat tar. GILBERT T. MORGAN AND GODFREY E. SCHARFF. *Economic Proc. of the Royal Dublin Society* 2, No. 10, 161-7(1915).—This paper deals with the distn. of samples of peat tar obtained by the incomplete combustion of peat in a gas producer. The tar was collected in hydraulic scrubbers. Such tar can also be obtained by the destructive distn. of peat in a closed retort. On distn. this tar yields (1) neutral oils differing from aromatic

coal-tar oil and from the paraffins in having a highly unsatd. character, shown by rapid absorption of oxygen, (2) acidic oils consisting of higher homologs of phenol having great germicidal power, (3) higher boiling neutral oils similar to montan waxes, and (4) a typical soft pitch. Crude peat tar also contains small amounts of bases of the pyridine group.

F. L. GROVER.

Report of committee D-6 on standard specifications for coke. J. A. HOLMES, *et al.* *Proc. Am. Soc. Testing Materials* 15, Pt. I, 359-61(1915) and *Year Book* 1915, 55-62.—The committee has been working along 4 lines, *vis.*: (1) method of sampling coke; (2) standard methods of chem. analysis; (3) methods for physical testing; and (4) specifications for foundry coke. In this report they submit tentative specifications for foundry coke only. In sampling, a quantity of not less than 2 pecks shall be taken from each car by breaking walnut sizes from the exposed lumps at intervals of 18 in. along 3 lines, one running through the middle and the others 2 ft. from the respective sides. The gross sample is crushed (avoiding all rubbing action) to 4-mesh, mixed, and quartered to 5 lbs. At the option of the purchaser this may be used also for the approx. moisture detn. The methods of chem. analysis will not be available before the end of another year. The dry coke compn. shall not exceed the following values: volatile matter 2, ash 12, S 1%, while fixed C must reach 86%. They consider the compressive-strength test as detd. on 1-in. cubes worthless for purposes of comparison and other physical tests too indefinite to warrant their incorporation into standard specification at present.

H. L. OLIN.

Briquetting coke-fines with hard pitch. G. BEHR. *Z. Beleuchtungsw.* 21, 102 (1915).—Review of modern German methods.

C. G. F.

Technical bitumens (CHURCH) 22. Distillation of Douglas fir at high temperatures (TREMPPER) 22. **Philippine coal beds (PRATT) 8.**

Heat-treatment of peat. N. TÆSTRUP and T. RIGBY. U. S., 1,160,463-4, Nov. 16. The peat is heated to a "wet carbonizing" temp. while flowing through pipes with sufficient velocity to prevent deposition of the material in the pipes.

Intermittent production of gas from bituminous fuels. P. KOSTER. U. S., 1,160,908, Nov. 16. A bed of fuel is heated by a down blast, the blast is shut off and air and steam are passed upwardly through the fuel to support combustion and generate gas.

Continuous manufacture of coal and water gas. J. W. HORNSBY. U. S., 1,159,675, Nov. 9. Finely divided coal is heated successively in rotating retorts, first to form coal gas and then in another retort to form water gas, while being showered repeatedly in each of the retorts through the hot gases within them.

Removing hydrogen sulfide from coal gas and other gases. K. BURKHUISER. U. S., 1,160,375, Nov. 16. The gas is treated with an emulsion containing free S, Fe_2O_3 and NH_4OH to remove the H_2S . The resulting mixt. of sulfides and free S is then treated with $(\text{NH}_4)_2\text{S}$ or other alkali sulfide to remove free S, the remaining sulfides are oxidized by air to form oxides and free S and this mixt. is re-used for further gas-purification. Cf. C. A. 9, 1243.

Purifying gases from the dry distillation of coal and recovering by-products. K. BURKHUISER. U. S., 1,160,836, Nov. 16. The gas is treated with S and a soln. of NH_4OH (from the gas itself) or other alk. reagent to remove H_2S ; the alk. soln. is regenerated with Fe oxide. The S sepd. from the gas is converted into SO_2 or SO_3 and then employed to combine with the NH_3 in the gas.

Gas producer. W. B. CHAPMAN. U. S., 1,162,452, Nov. 30.

Gas producer. J. A. HERRICK. U. S., 1,162,357, Nov. 30.

Rotating gas producer. W. J. LINDSAY. U. S., 1,160,516, Nov. 16. The pat. relates principally to devices for rotating the producer and operating its stirring mechanism.

Gas producer. H. KOPPERS. Brit., 17,678, July 25, 1914. In a producer in which the slag is withdrawn in liquid form, a portion of the gas produced is discharged, with the slag, through the slag-discharge passage to prevent solidification of the slag.

Gas producers. H. J. GREEN. Brit., 17,687, July 27, 1914. In a gas-producer, the raw fuel is fed in small charges into the high-temp. zone in the lower part of the producer, and the body of fuel in such lower part is at the same time rotated, the raw fuel being thus evenly distributed in the high temp. zone. The rotation of the fuel is effected by means of a rotary ribbed fuel support assisted, if desired, by rotation of the upper part of the producer shell in the same direction. The lower part of the producer shell, which in either modification is stationary, is preferably a truncated cone, which may be fire-brick lined, or a water-cooled metal structure.

Gasifying peat. T. RIGBY and WETCARBONIZING, LTD. Brit., 16,918, July 16, 1914. In gasifying mixts. containing or consisting of peat in different conditions, the moisture content of the mixt. is maintained approx. const. by controlling the proportions of the constituents of the mixt.

Separation of tar from gas. BERLIN ANHALTISCHE-MASCHINENBAU AKT.-GES. Brit., 16,981, July 17, 1914. In a tar-separator of the kind comprizing 1 or more walls each consisting of 2 perforated casings, the outer casing of each pair is connected to the cover and inner casing so as to be readily detachable. Each outer casing may be divided vertically and held in place by clamping members or the like.

Peat; ammonia. B. F. HALVORSEN. Brit., 17,882, July 28, 1914. Acids or salts are added to peat before heating under pressure to a temp. of 160-300°, whereby a large proportion of the N present is converted into NH_3 and recovered from the liquid, which is subsequently sepd. from the peat fuel. Suitable chemicals mentioned are HCl , H_2SO_4 , and SO_2 , Fe chloride and sulfate, chloride of Ca, Mg, or Na, kainite and bisulfides. HNO_3 and nitrates are not suitable. MgCl_2 may be added as such, or may be heated to give HCl , which is added to the peat, and a basic chloride which replaces lime for use in distg. off the NH_3 . The crude peat may be dealt with directly, or being cut and dried on the moor. After heating in digesters or tubular app., the is pressed to sep. the ammoniacal liquid, which is distd. with lime, etc., in a column the NH_3 being absorbed by H_2O or acids. The solid residue is washed and made dried and briquetted for fuel. Slightly dried peat may be treated with an excess acid, the expressed liquid partially evapd. and used for the treatment of fresh peat.

Ammonia salts; purifying gas. F. DUVEIGUSART. Brit., 17,475, July 23, 1914. Gases are freed from NH_3 and H_2S by washing with a soln. of sulfited tar bases, which may be made by treating tar or tar oil with SO_2 and washing out the products with H_2O or salt solns., or by treating a mixt. of tar or tar oil and H_2O or salt soln. with SO_2 , or by treating crude tar oil with H_2SO_4 , displacing the tar bases with Na_2CO_3 and treating the bases with SO_2 and H_2O or salt soln. The liquor may be successively treated with SO_2 and crude gas until sufficiently concd., whereupon it may be removed for sepn. of $(\text{NH}_4)_2\text{SO}_4$. The mother liquor may be used again or mixed with fresh sulfited tar bases.

Coking. A. M. DUCKHAM. Brit., 17,502, July 23, 1914. Coal is coked in continuous vertical retorts while subjected to mechanical pressure uniformly applied over the cross-section of the charge and exerted constantly except during the short interval required for the admission of fuel.

Cooling coke. W. WALCH. Brit., 17,236, July 21, 1914. Incandescent coke is cooled by a current of inert gases, *e. g.*, waste combustion products, and the heat abstracted is utilized in a suitable heat-exchanging app. The coke may be cooled either in the oven itself, or after discharge into a sep. cooling chamber, and the gases from the heat-exchanger are preferably used over again for cooling. In one form described, the inert gases are passed in a circuit through the coke to be cooled, through the heating flues of another oven, and through a heat-exchanger back to the cooling coke. The supply of heat to the exchanger may be equalized by passing through it gases from chambers at different stages of the cooling process. When the heat abstracted from the coke is utilized for heating air, the temp. of the cooling gases may be first reduced in a water heater. The sep. cooling chambers employed may be transportable, so that the partially cooled coke may be transferred directly to the blast furnace.

Gas generator. H. KOPPERS. Ger., 285,112, July 4, 1914. Construction and operation of charging mechanism.

Firing furnaces with gaseous, liquid, or powdered fuel. APPARAT-VERTRIEBS-GES. M. B. H. Ger., 285,418, July 2, 1914. An automatic regulation of the fuel and air supplies is controlled by the combustion temp.

22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

F. M. ROGERS.

Thermal reactions of petroleum hydrocarbons in the vapor phase. W. F. RITTMAN. *J. Ind. Eng. Chem.* 7, 945-53(1915).—The author discusses theoretically the cracking reactions of hydrocarbons under the influence of heat and pressure. He gives experimental results of cracking Penn. kerosene, Okla. fuel oil and Cal. crude oil under varying conditions of temp. and pressure. These results indicate that the products of cracking are independent of the chem. and phys. properties of the original oils, but are dependent on the conditions of temp. and pressure. C formation is a marked exception to this, its formation being proportional to the amt. originally contained in the oil. The formation of aromatic hydrocarbons occurs best at moderate to high temp. and under high pressure; that of gasoline is favored by moderate to low temp. and high pressure.

F. M. ROGERS.

Viscosity and rate of flow of hydrocarbon oils. R. T. GLAZEBROOK, W. F. HIGGINS AND J. R. PANNELL. *Engineering* 100, 522-4(1915); *Gas World* 63, 515(1915).—The authors report in detail expts. on oils from Borneo, Persia, Mexico, Texas, Trinidad, Scotch, and Kimmeridge shales. The object of the research was to investigate the laws of flow of the oil in drawn-steel pipes of 3, 4 and 5 in. diam., with a view to detg. how far the pressure difference required to produce a given flow could be calcd. from a knowledge of the pipe dimensions and the viscosity of the oil. The results indicate that the ordinary laws of viscous flow hold so long as the velocity of flow is less than the "critical velocity," which is given by the equation: $\rho Vd/\eta = 2500$, where V is the velocity of flow in ft. per sec., d the diam. of the pipe in ft., ρ the density, and η the viscosity coeff. of the oil expressed in ft.-lb.-sec. units. In this case $P/V = 2\eta/9gd^2$, P being the pressure difference in lbs. per sq. in. per ft. run, and g the gravity acceleration in ft.-sec. units. The d. of mixts. of oils at 15.5° was found to be in accordance with the calcns.; but there was apparently no simple law connecting the viscosity of a mixt. with the viscosity of the components, the addition of a low-viscosity oil to a high-viscosity oil producing in general a much greater decrease in the viscosity of the mixt. than would result from the law of proportion, *e. g.*, the addition of 10% of Scotch shale oil (of low viscosity) to Mexican oil reduced the viscosity from 72×10^{-2} to

15.3×10^{-3} ; 50% mixts. = 4.25×10^{-3} . The flash point of mixts. is likewise reduced, and in some cases is lower than that of either constituent. Thus it may happen that 2 oils which individually comply with a specification regarding flash point, may, when mixed in certain proportions, produce a mixt. which flashes below the specified limit. Expts. with mixts. of oils from different sources showed sepn. was very slight, and that the storage of mixts. would not appear to call for special precautions. F. W. S.

Petroleum and residual bitumens in Leyte. W. E. PRATT. *Philippine J. Sci.* 10A, 241-78(1915).—In Leyte, in the Philippine Islands, petroleum and residual bitumens occur in the Canguinsa sandstone and Malumbany limestone and calcareous sandstone. The crude oil is a light, fluid oil, olive-green color, sp. gr. 0.8597, contains 8.14% of paraffin scale, and yields 5.4% gasoline, 33.7% kerosene, 55.3% of heavy oils, and 5.6% of residual pitch. Several samples of the residual bitumens gave from 26 to 94.53% of bitumen sol. in CS_2 , from 36.78 to 2.88% of mineral matter, 7.68 to 26.62% of fixed carbon, 0.30 to 21.6% of paraffin scale, and had sp. grs. varying from 1.016 to 1.068. No large deposits of petroleum seem to exist. At some places the presence of very large deposits of residual bitumen or rock asphalt is indicated. The geology of the oil- and asphalt-bearing rocks and strata are described in detail. O. E. B.

The occurrence of petroleum in the province of Cebu. W. E. PRATT. *Philippine J. Sci.* 10A, 281-6(1915).—A sample of crude oil obtained from Toledo, Cebu, possessed a sp. gr. of 0.885, and yielded 6.2% of gasoline, 42.32% of kerosene, 38.3% of heavy oils, and 13.17% of residue. O. E. BRANSKY.

The utilization of aromatic hydrocarbons derived from cracked petroleum. W. F. RITTMAN. *J. Ind. Eng. Chem.* 7, 1014-9(1915).—"The aromatic hydrocarbons produced by the cracking of petroleum may be utilized for the prepn. of nitro products without being brought to a high state of purity. The foreign substances not easily removable are paraffins and these are not affected by reagents of sufficient vigor to transform the aromatics quantitatively into mononitro products. These compds. may be sepd. in a high degree of purity by a simple process of distn. The mononitrotoluene prepd. by the method indicated may be readily converted into trinitrotoluene, which, when washed with hot water, satisfies the ordinary commercial specification of a m. p. of 75° ."

CHESTER TISTIG.

Some experiments on technical bitumens. S. R. CHURCH AND J. M. WEISS. *Proc. Am. Soc. Testing Materials* 15, II, 274-96(1915).—The object of the investigation was to afford a comparison, by means of laboratory analyses, of 18 varieties of asphalts and tar pitches; and to subject test specimens of the same materials to exposure tests. The procedure and results of these exposure tests are fully described. It is shown that: (a) A moderate degree of overheating does not seriously affect the bitumens tested; (b) gas drip attacks all the bitumens tested, but some resist its action for a longer time than others; (c) in an atm. of illuminating gas, at 15.6° for 6 days, some of the bitumens are measurably softened; (d) after exposure to sunlight and air for one yr., while the exposed surfaces of the bitumens tested has manifestly undergone marked change as evidenced by photographs of these surfaces, analyses of the test specimens show only slight physical or chem. changes. Additional exposure tests, including effect of O and N gas at 100° , and effect of H_2O , dil. acid and dil. alkali solns., are described, but the results are not given because of incompleteness. Further investigation is contemplated. F. W. SMITHER.

Application of the Davis spot test in preliminary examination of creosotes. H. CLOUKY. *J. Ind. Eng. Chem.* 7, 923-4(1915).—Six drops of sample are dropped from buret on clean, white blotting paper. If tar, carbon or dirt is present, it is observed to segregate at the center. After several hours' standing in an atm. free from

dust, foreign matter will occupy a distinct zone in the center of the spot and the outer zone clearly indicates the character of the oil. Experience in application of this test and a large number of authentic samples for comparison are necessary, but it is possible to ascertain the constituents with a reasonable degree of accuracy.

C. N. WILEY.

Yield of by-products from the destructive distillation of some western conifers. H. K. BENSON AND M. DARRIN. *J. Ind. Eng. Chem.* 7, 916-8(1915).—The common run mill waste, the selected mill waste, and the common run stump wood of Douglas fir, western yellow pine, and western hemlock were distd. The turpentine and light oil are made to include oils of a turpentine character. Tar embraces the retort and still residues. In distg. these tars, wood creosote, fir oil, turpentine, and other wood oils are obtained. The Ca acetate in the table below was computed from the titration of the aq. distillate with KOH. The results of the distn. are given in the following table:

Douglas fir.	Lbs.	(Light oils. Turpentine.) Gal.	Tar. Gal.	Wood alcohol. Gal.	Calcium acetate. Lbs.	Char- coal. Lbs.
Common run mill waste...	3,330	3.40	27.80	3.9	75.0	977
Selected mill waste.....	4,250	10.86	46.37	3.71	74.3	900
Common run stump wood..	3,260	5.59	19.88	2.60	55.8	675
Western yellow pine.						
Common run mill waste...	2,840	4.91	24.80	3.25	73.4	478
Common run stump wood..	2,620	6.06	23.05	1.83	60.8	520
Western hemlock.						
Common run mill waste...	3,270	2.76	21.60	5.00	94.0	938

The wts. of the original material are the av. wts. of measured cords. From the Douglas fir stump wood distn. 6,270 cu. ft. of gas and from the western yellow pine stump wood 3,950 cu. ft. were obtained.

O. E. BRANSKY.

Distillation of Douglas fir at high temperatures. B. TREMPER. *J. Ind. Eng. Chem.* 7, 926-7(1915).—In the Pacific Northwest several plants for the manuf. of illuminating gas from saw-mill waste are in operation. Standard coal gas installations are employed, consisting of benches of four 9-ft. clay retorts, connected to a hydraulic main, condenser, exhauster, and dry scrubbers. The accumulation of tar in the pipes is overcome by water-jacketing the standpipes. The bench is maintained at 1400° to 1600° F., and holds a charge of 1/4 cord. Twelve changes can be made in 24 hrs., giving a gas output of 60,000 cu. ft. The by-products are chiefly tar and charcoal. The MeOH, acetic acid, acetone, and part of the tar are decompd. under the temp. of distn. From Douglas fir forest wood, 25,000 cu. ft. of gas with a B. t. u. of 482 are obtained per cord of 37,000 lbs. From the mill waste, 18,000 cu. ft. of gas are obtained with a heating value of 475 B. t. u. from a cord of 33,000 lbs. Enough tar is produced to pay for the cost of the wood. Charcoal is obtained at the rate of 700 to 800 lbs. per cord.

O. E. BRANSKY.

Acetone from pyroligneous acid. M. DARRIN. *J. Ind. Eng. Chem.* 7, 927-9 (1915).—The method of producing acetone from pyroligneous acid by means of a continuously operated elec. furnace, containing a catalyzer, which converts the acid directly to acetone, gives promising results. The acid is heated in a round-bottom flask, and the acid vapors are led into a quartz tube, heated electrically, and containing the catalyzer. The vapors leaving the furnace are then condensed. The % of acetone from pure acetic acid is about 85% of the theoretical. The yield from pyroligneous acid is also about 85%. The most suitable temp. in the furnace is 435°. Barium acetate was used as catalyzer; it showed only slight deterioration in 30 days. The advantages of this method are: higher yields of acetone, elimination of the large

consumption of lime, no drying of acetate (as in the lime process), continuous operation, low operating expense, low cost and easy control of conditions. O. E. B.

Waste pine wood utilization. J. E. TEEPLE. *J. Ind. Eng. Chem.* 7, 929-30 (1915).—A review is given of the processes for the utilization of waste pine wood. The use of a volatile solvent for the extrn. of turpentine, pine oil and rosin is the best of these processes. O. E. BRANSKY.

Discoloration of maple in the kiln. R. C. JUDD. *J. Ind. Eng. Chem.* 7, 920 (1915).—The brown stain that forms in kiln-drying green frozen maple lumber is not caused by an enzyme; it is of a physico-chem. nature. Boiling and steaming before drying or preliminary treatment with solns. of germicides did not prevent discoloration. No staining occurred when the humidity of the air in the immediate contact with the drying wood was kept low. Heated in an autoclave in an atm. of SO_2 , CO_2 , and in the presence of H_2O_2 and NH_4OH , fresh green maple does not stain. O. E. BRANSKY.

Manufacture of ethyl alcohol from wood waste. II. The hydrolysis of white spruce. III. Western larch as raw material. F. W. KRESSMANN. *J. Ind. Eng. Chem.* 7, 920-3 (1915).—The best conditions for the extrn. of the sugars in white spruce are the following: a ratio of water to dry wood of 125 to 100, of H_2SO_4 to dry wood of $2\frac{1}{2}$ to 100, a pressure of $7\frac{1}{2}$ atms., and 20 min. cooking. Under these conditions, a yield of 23.6% of sugar was obtained, of which 71.44% was fermentable, giving 8.54% of EtOH upon the basis of dry wood. A sample of sawdust from a butt log of the western larch was cooked with 125% of water, 1.8% of H_2SO_4 , at 7.5 atms., for 10 mins. From this ext. a yield of 29.72% of sugar was obtained, of which 37.9% was fermentable. The yield of EtOH, based upon the original dry wood, was 4.997%. O. E. BRANSKY.

The use of ammonium hydroxide for the extraction of rosin from wood. H. K. BENSON AND H. N. CRITES. *J. Ind. Eng. Chem.* 7, 918-20 (1915).—Expts. were made with fir wood. The rosin was extd. with NH_4OH , the soln. boiled to drive off NH_3 and evapd. to dryness, the rosin dissolved in gasoline and subsequently recovered. The effects of variation in strength of NH_4OH soln., temp., time, etc., were studied. The conclusions are as follows: (1) When resinous wood is treated with a 5% soln. of NH_4OH equal to 8 times the wt. of the wood at 70° for 5 hrs., nearly complete extrn. of rosin occurs. (2) From the general properties of NH_3 and its complete recovery in gas works, it is believed that nearly complete extrn. of rosin from wood may be made and complete recovery of NH_3 obtained. E. W. BOUGHTON.

A cylinder friction and lubrication testing apparatus (FLOWERS) 1. Composition of wood turpentine (ADAMS) 26.

Apparatus for fractional distillation of petroleum. J. T. DAVIS. U. S., 1,159,186, Nov. 2.

Distilling heavy hydrocarbon oils. J. ROSEN. U. S., 1,162,654, Nov. 30. Heavy mixed hydrocarbons, e. g., petroleum residues, are fractionated by gradually increasing their temp. in a still and successively introducing, during the distn., lighter hydrocarbons, b. 30° to 150° lower than the distillate passing off at the time, to serve as carriers to facilitate the distn.

Refining crude petroleum. F. SEIDENSCHNUR and J. DEHNST. U. S., 1,162,729, Nov. 30. Crude petroleum is atomized at 380 – 400° into a vessel within which the pressure is reduced and superheated steam at a temp. of 450 – 500° is introduced into the heated atomized oil in amt. equal to 30–40% of the oil. The temp. of the latter

is raised to 420–430° and 90–95% of the vapors are sepd. and collected by fractional condensation.

Continuous process of cracking petroleum. W. P. THOMPSON. U. S., 1,160,670, Nov. 16. Petroleum, previously freed from any As and S by treatment with acid and alkali, is passed through the pipe C into the cracking still A, from the tank T, together with H from the tank S, and from time to time finely divided Ni is also supplied from the receptacle R and forced into the still with the oil and H (or water gas which may be used instead of pure H). Light hydrocarbons are produced which are collected in the tank L after passing through the condenser G and excess gases are returned from the outlet N (by a pipe not shown) to the inlet O for reuse.

Purifying crude wood tar and pitch. H. M. CHASE and J. L. GRAFFLIN. U. S., 1,161,844, Nov. 30. The tar or pitch is heated to about 260° or a somewhat lower temp. until all creosote oil and similar substances are driven off and then the temp. is raised to about 370° or slightly lower to distil off other wood tar oils free from any odor of creosote.

Purifying tarry residuums obtained from the distillation of resinous woods. H. M. CHASE and J. L. GRAFFLIN. U. S., 1,162,036, Nov. 30. Superheated steam is blown through the material in the still to heat it to about 200° or slightly lower, with the aid of heat applied externally to the containing vessel if desired, until all the oil having an odor similar to creosote is distd. and the temp. is then raised to about 260° or slightly lower to distil the remaining oil, which is free from creosote odor.

Cracking oils. P. SABATIER and A. MAILHE. Brit., 16,791, July 14, 1914. In cracking oils by passing their vapors over a catalyst at temps. between 400° and dark red heat, the catalyst is formed of finely divided metal or metals, or metallic oxides or salts that can be reduced to form divided metal, together with neutral refractory substances free from SiO_2 , and an agglutinant free from SiO_2 . Suitable refractory materials are MgO , Al_2O_3 , bauxite, lime, baryta, strontia, or the corresponding carbonate, or graphite. Suitable agglutinants are glue, dextrin, and starch. Examples of such compns. comprize: (1) Fe filings, MgO , and dextrin; (2) oxide of Fe, Mg, bauxite, and glue; (3) finely divided Fe, Al_2O_3 , and dextrin. The resulting compns. are molded and dried, and packed into cracking-tubes composed of metal or earthenware lined with a non-siliceous coating. When the catalyst loses its activity by reason of the deposition of C, it is revived by the passage of steam, a gaseous mixt. of H, CO, and CO_2 being produced. This gas can be utilized as a reducing agent or fuel, the CO_2 being removed by washing if necessary. The metallic oxide formed by the steam, and the oxide used in making the catalyst initially, are reduced to metal by means of hydrocarbon vapors. The volatile portion of the products of the cracking operation, namely that distg. below 150°, is treated for the removal of the malodorous unsatd. compds. by reduction with H in the presence of divided metals at 150–300°.

Distilling and cracking oils. A. F. G. C. P. J. VON GROELING. Brit., 16,713, July 13, 1914. Crude oil, oil residues, etc., are distd. or cracked in a still to which preheated oil is admitted by spray-producers and which is heated by pipes through which circulates oil heated in a boiler under a pressure greater than that obtaining in the still. A pump fills the boiler with crude oil at the beginning of the operation, and afterwards supplies sufficient residual oil from the base of the still to maintain

the requisite pressure in the boiler. The oil is circulated through the boiler and heating pipes by means of a pump, and a regulated quantity is allowed to escape through a pipe into the still, where it vaporizes. Superheated steam may also be admitted at the base of the still.

Motor spirit. W. A. HALL. Brit., 16,857, July 15, 1914. Oils suitable for cracking to yield motor spirit are obtained by heating a mixt. of bituminous coal or lignite with coke or the like in granular form gradually to a temp. of about 500° in an externally heated retort, and condensing the volatile matter evolved. The coal or lignite is preferably not coarser than pea size, and the coke may be replaced by breeze, charcoal, peat, or like carbonaceous material. The proportion of coke, etc., should be from 10 to 20% or higher. Cf. C. A. 9, 1994.

Mineral oil and wax emulsions. M. HAMBURG. Brit., 26,390, Nov. 17, 1913. Emulsions, suitable for use in medicine and as a nutrient, and also in the manuf. of sizes and finishes for fabrics and yarns, and of thickenings for color printing, are composed of a dry, pulverizable prepn. made from malt ext., or malto-dextrin sirup, emulsified with mineral oils, or mineral solids which when melted yield oils, instead of with fats and fatty oils as described in 29,481, 1912 (C. A. 8, 2033).

Compressed wood scrap. A. BEZNER. Ger., 284,763, July 15, 1913.

23. CELLULOSE AND PAPER.

A. D. LITTLE.

Characteristics of fibers. H. A. MADDOX. *Pulp Paper Mag. Can.* 13, 551-3 (1915). V. NUNEZ.

Vulcanized fiber. CHARLES ALMY, JR. *Met. Chem. Eng.* 13, 746-7 (1915).—A brief description of the manufacture is given. Valuable properties are emphasized. The great variation in fiber due to methods of manufacture requires that each user give careful study to find the most suitable fiber for his purpose. V. NUNEZ.

Normal papers 1914. W. HERZBERG. *Mitt. kgl. Materialprüfungsamt.* 31, 72-80 (1915).—Of 865 papers tested during 1914, 42.5% were above, 50.9% equal to and 6.6% below the normal specifications as to strength or compn. V. NUNEZ.

Design and equipment of a paper and pulp mill laboratory. ANON. *Pulp Paper Mag. Can.* 13, 503-10 (1915). V. NUNEZ.

Chestnut as a pulp wood. P. L. BUTTRICK. *Pulp Paper Mag. Can.* 13, 554-5 (1915).—Discussion from the standpoint of growth and yield. V. NUNEZ.

New fibers for paper making. W. H. ROBERTSON. *Commerce Reports* No. 250, 360-1 (1915).—The Argentine Bureau of Forestry has carried out successful expts. in the production of paper-pulp from the pines (*Araucaria imbricata*) of Neuquen territory. Other new sources of pulp are the Misiones pines, an Indian weed (*Hedy-chium coronarium*) and hop vines. E. H.

Diminishing fuzz in soda pulp by proper cooking conditions. S. D. WELLS. *Paper* 17, No. 4, 14-5 (1915).—To diminish fuzz in the sheet cooking with as low a percentage NaOH as practicable seems desirable. Thorough cooking is obtained under these conditions by using higher pressures, greater concn. of liquor, etc. V. NUNEZ.

Reducing losses in the ground wood mill. D. L. BILLINGER. *Paper* 17, No. 4, 11-3 (1915).—Factors in refining ground wood slivers. V. NUNEZ.

The use of ... *Paper Makers' Monthly* 53, 250-1 (1915).—Enumeration of ... E. J. KELLEY.

Calcium hydrogen sulfite liquor. H. O. V. BERGSTRÖM. U. S., 1,159,352, Nov. 9. In making sulfite cellulose, vapors from the sulfite boilers are passed to a condenser. The SO_2 remaining, uncondensed, is reused in the pulp-making process and the condensate is heated to drive off an additional quantity of SO_2 and organic compds. which are passed into a second condenser, whence the SO_2 is led back for further use in the process. The second condensate is heated to obtain more SO_2 which is led back through another condenser.

Preparing resinous materials for the manufacture of paper pulp. S. F. LAGERMARCK and W. Sverdrup. U. S., 1,161,696, Nov. 23. About 8% of talcum, kaolin, BaSO_4 or other filler is added to the material after it comes from the digester and has been washed in the hutches (but before diln. with H_2O) in order to envelop the particles of resin which are disseminated throughout the mass with the filler and thus destroy their adhesive property.

Bleaching paper pulp. K. MORCH. U. S., 1,160,942, Nov. 16. Pulp containing about 20–22% of dry material is kneaded with the required amt. of bleaching agent, and after thoroughly working the latter into the fibers, the mixt. is agitated until the bleaching is completed.

Waterproofing paper or cardboard for bottles, etc. A. WESTLAKE and P. Poetschke. U. S., 1,160,478, Nov. 16. An emulsion prepd. from H_2O 78.5, rosin 10, shellac 10, and Na_2CO_3 1.5% (with or without CaSO_4 or other filler) is incorporated in the pulp while making the paper and alum is subsequently added as a pptg. agent.

Waterproofing paper. E. S. COLEMAN. U. S., 1,158,897, Nov. 2. Gutta percha 1 (dissolved in CHCl_3) is mixed with olive oil 2 and alc. 2 parts.

Celluloid-substitute and moving-picture film composition. W. A. BEATTY. U. S., 1,158,960, Nov. 2. Cellulose acetate is combined with about 35% its wt. of dihydroxyphenyldimethylmethane by use of alc., CHCl_3 or other common solvent.

Celluloid substitute and moving-picture film composition. W. A. BEATTY. U. S., 1,158,961, Nov. 2. Nitrocellulose is combined with about 25% its wt. of dihydroxyphenyldimethylmethane, using amyl acetate and acetone or other common solvent.

Sizing and coloring paper. E. FURS. Brit., 13,970, June 9, 1914. Sizing paper and other absorbent material in one operation with a mixt. of solns. containing precipitable sizing agents, precipitants, and substances acting as protective colloids for preventing the pptn. of the sizing agents, the sizing being completed by drying the material. Dyestuffs may be added to the above mixt., giving simultaneous sizing and coloring. Examples of precipitable sizing agents are solns. of fatty acids, shellac, albumin, casein; of protective colloids, animal size, gum arabic, or the like; of precipitants, alum, $\text{Al}_2(\text{SO}_4)_3$, and other acid salts or acids, or the like. In the application of coloring matters, the presence of the protective colloids enables the simultaneous use of mutually pptg. dyestuffs, *e. g.*, a basic yellow and an acid blue to obtain a green sizing liquid.

24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE

Static electricity as a cause of explosions. H. ZSCHIEGNER. *J. Ind. Eng. Chem.* 7, 1083–4 (1915).—The theory held by Major Cooper-Key in regard to a recent explosion of cordite in Stowmarket factory as being caused by static electricity is considered not far-fetched in view of Z.'s experience. He recounts having drawn a spark from silk fabrics after they had been agitated in a closed vessel of anhydrous petroleum ether for 45 min. The absence of air in the vapors precluded the possibility of explosion. Cf. Munroe, *J. Am. Chem. Soc.* 21, 317 (1899). CHESTER TURTIG.

Utilization of aromatic hydrocarbons derived from cracked petroleum (RITTMAN)
22.

Explosives. I. B. T. VON TARNOW. Brit., 16,681, July 13, 1914. An explosive is obtained by mixing NH_4ClO_4 , Al powder, and a nitrohydrocarbon of the aromatic group, such as mono-, di-, and trinitrobenzene and -toluene, and tetranitroaniline and -methylaniline. To such mixt. the following substances may also be added: nitrocellulose or collodion, wood meal or cellulose, paraffin wax, and nitrates of Ba and K. One example contains 40% NH_4ClO_4 , 9% Al, 12% trinitrotoluene, 9% wood meal or cellulose, and 30% KNO_3 .

Explosives. W. RINTOUL, N. PICTON and D. H. PRACOCK. Brit., 16,692, July 13, 1914. Using nitrated furoxans, i. e., nitrated nitroso compds. of benzene, naphthalene, and other like compds., and their K, Na, and other salts as explosive ingredients in detonators, shells, and torpedoes. E. g., dinitrodinitrosobenzene may be used in detonators in the place of tetranitroaniline and other well known substances. Dinitrodinitrosobenzene is obtained by nitrating dinitrosobenzene, which is itself obtained by treating *o*-nitroaniline with alc. KOH and NaOCl or bleaching powder.

Trinitrotoluene. OBERSCHLESISCHE AKT.-GES. FÜR FABRIKATION VON LIGNOSE SCHIESSWOLFFABRIK FÜR ARMEE UND MARINE. Brit., 17,003, July 17, 1914. See Ger., 277,325 (C. A. 9, 526).

Stiffing mine explosions. R. CREMER. Ger., 284,396, Jan. 21, 1913. Incombustible dust, in readily breakable packages, is suitably disposed in the workings. (Cf. C. A. 9, 1845.)

25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

Dyestuff situation. E. E. PRATT, J. F. SCHOELLKOPF, T. H. NORTON, W. H. CHILDS, J. M. MATTHEWS, J. P. WOOD, JOHN ALDEN, W. H. NICHOLS, WM. BECKERS, H. A. METZ AND M. T. BOGERT. *Met. Chem. Eng.* 13, 779-82(1915); *J. Soc. Chem. Ind.* 34, 1182-95(1915).—Papers and discussion before the N. Y. Section of Soc. Chem. Ind. L. W. RIGGS.

The coal-tar industry in the U. S. A. K. PIETRUSKY. *Chem. Ind.* 38, 199-202 (1915).—A review of the reports of the U. S. Dept. of Commerce. F. W. S.

Reductions with sulfur-alkali sulfide solution. A. COBENZL. *Chem. Ztg.* 39, 859-60(1915).—As examples of reduction with the soln. directions are given for prep. *p*-aminodiphenylamine, 4-phenylaminoquinoline, *p*-aminodiphenylaminesulfonic acid, *o*-nitro-*p*-aminodiphenylamine, *p*-aminomethyldiphenylamine, 1,4-naphthylenediamine, 1,4-dimethyl- α -naphthylenediamine, 1,4-phenyl- α -naphthylenediamine, amino- α -dinaphthylamine, *p*-anisidine and *m*-phenetidine. J. H. MOORE.

Domestic plants and plant substances that may be used as possible substitutes for plant materials previously imported. HALLE. *Kunststoffe* 5, 253-6(1915).—A review and discussion, mainly of the patent literature, of possible substitutes for such materials as jute, ramie, etc., inaccessible on account of the war. SMITHER.

The durability of field-gray cloth. E. SELL. *Z. angew. Chem.* 28, I, 412-6, 428-31(1915).—S. gives a review of the literature of the subject and presents exptl. work carried out to determine conditions under which the material is most durable. A microscopic study (800 $\times$) of threads drawn from the cloth shows a greater stretching of the wool fibers than of the cotton fibers, however the wool is dyed with alkaline indigo than

when dyed with acid dye. NaOH has a more pronounced effect than NH_4OH . The manner of double dyeing wool in alk. and acid soln. can prove injurious to the fabric. Numerous illustrations of the microscopic appearance of the fibers are given.

L. T. FAIRHALL.

Difference in weight between raw and clean wools. WALTER S. LEWIS. *Chem. Eng.* 22, 197-8(1915).—Forty-nine fleeces were carefully sampled and detns. of shrinkage made in duplicate. Grease was extd. with warm water and pure olive oil soap, after which the soap was washed out and the slight amt. of fat remaining extd. with ether. Results show shrinkages varying from 19 to 54%, according to the breed of sheep. The greatest variations in shrinkage of samples from the same fleece was 3% for Australian and 6% for New Zealand wools. Two fleeces from the same breed may vary in their shrinkages from 1-9%, av. 4.5% in 13 breeds examd. As might be expected, fleeces from full-blooded or grade merinos gave the highest shrinkage, being often double that of fleeces from Lincoln, Leicester and Romney breeds.

L. W. RIGGS.

Waterproofing methods. K. MICKSCH. *Kunststoffe* 5, 229-32, 243-5, 257-8 (1915).—A brief review and discussion of the impregnation methods of waterproofing textiles.

SMITHER.

Azo dye. O. GÜNTHER. U. S., 1,159,375, Nov. 9. A dye is made by combining diazotized anthranilic acid with 2-amino-5-naphthol-7-sulfonic acid and 4-nitro-2-aminophenol. It is a dark powder sol. in H_2O with a red-violet color and in concd. H_2SO_4 with a blue-violet color and dyes Bordeaux-red on wool in acid baths changing to fast greenish black on chroming. Instead of anthranilic acid, its compds. may be used to form similar dyes, e. g., chloro- or nitroanthranilic acid, together with other *o*-aminophenol compds. such as picramic acid, 4-chloro-2-aminophenol, 2-amino-1-phenol-4-sulfonic acid, 2,3-aminonaphthol-6-sulfonic acid and phenyl-2,5-aminonaphthol-7-sulfonic acid and other aryl or alkyl derivs. may be used instead of 2,5-aminonaphthol-7-sulfonic acid.

Yellow azo dye. J. HUISMANN. U. S., 1,159,386, Nov. 9. A dye is made by combining diazotized Na dehydrothiotoluidinedisulfonate with acetoacetic *o*-anisidide. It is a yellow powder sol. in H_2O and in concd. H_2SO_4 with a yellow color and dyes cotton fast greenish yellow. Dehydrothiotoluidine heated *in vacuo* for 4-5 hrs. at 235-50° yields, with soda, Na dehydrothiotoluidinesulfonate, colorless leaflets yielding a difficultly sol. diazo compd. The disulfonic acid is made from it by heating with fuming H_2SO_4 .

Disazo dyes. M. HERZBERG. U. S., 1,160,406, Nov. 16. A dye is made by combining an alk. soln. of the tetraazo compd. of dianisidine with *m*-aminophenyl-5-hydroxynaphthimidazole-7-sulfonic acid and coupling the reaction product with 2-amino-5-naphthol-7-sulfonic acid. Its Na salt is a dark blue powder sol. in H_2O with a blue color and dyes cotton blue. Substitution of other starting components such as benzidine, toluidine, diaminodiphenylamine or its sulfonic acids or 2-phenyl- or ethylamino-5-naphthol-7-sulfonic acids or 2-amino-5-naphthol-1,7-disulfonic acid yield similar dyes.

Yellow disazo dyes. H. WAGNER and J. ERBER. U. S., 1,160,471, Nov. 16. A dye is made by combining the tetraazo compd. of diaminotriphenylmethane, in alk. soln., with 1-[2-chloro-5-sulfophenyl]-3-methyl-5-pyrazolone. It dyes wool and silk greenish yellow fast to milling, light and S. Tetraazotized diaminotriphenylmethane, combined with either alk. or HOAc soln., gives a similar dye with 1-[2-chlorophenyl]-3-methyl-5-pyrazolone.

Vat dyes of the anthraquinone series. A. L. LASKA and E. J. RATH. U. S., 1,162,496, Nov. 30. Yellow, red and brown dyes of various shades are formed by condensing *o*-aminoazo dyes with anthraquinone-aldehydes, *e. g.*, benzeneazo- β -naphthylamine with 2-anthraquinone-aldehyde (yellow) or the *o*-aminoazo dye from α -diazoanthraquinone and β -naphthylamine with 2-anthraquinone-aldehyde (orange).

Dyeing raw cotton. J. SCHMITZ. U. S., 1,160,001, Nov. 9. The cotton is rolled into small bats which are placed on end in a vat and dye liquor is then circulated through them.

Brownish yellow wool dye. R. SCHMIDLIN. U. S., 1,162,109, Nov. 30. A dye of the formula

is formed by combining Na phenylaminodiaminodiphenylamine-*m*-sulfonate with 1-chloro-2,4-dinitrobenzene. Its Na salt is a dark brown powder difficultly sol. in cold H_2O and readily sol. in hot H_2O and alc. The dye gives a brownish yellow color on wool, fast to washing, light and alkalis.

Chromium mordant. W. BECKERS and I. DREYFUS. U. S., 1,162,210, Nov. 30. Glucose and neutral Na_2CrO_4 are heated together in soln. and form a compd. which is not pptd. by mordant colors or alkalis and the soln. thus obtained is evaporated to dryness. The compd. is used with the dye to penetrate the fiber throughout and form a lake upon and within it.

Waterproofing textile fabrics, etc. W. A. BRATTY. U. S., 1,158,963, Nov. 2. The material is impregnated with a condensation product formed from dihydroxyphenyldimethylmethane and CH_2O . This condensation product may also be used as a floor polish, for waterproofing leather, in insulating compns. or paints, or as a binder in various plastic mixts., *e. g.*, with leather dust in making dress suit casts.

Dyeing on the fiber with quinoneanilide- or anilidoquinone-like dyes. M. BECKE. Aust., 6,664, Aug. 3, 1913. Aromatic amines, their sulfonic and carboxylic acids, or quinones of the benzene and naphthalene series and their derivs. forming, or which have already formed, dyes with free amino groups, are allowed to act in the dye bath or on the fiber.

Dyes. CASSELLA & Co. Brit., 17,319, July 21, 1914. Vat dyes are obtained by heating with S mixts. of 1-amino-2-methylantraquinone with aromatic monoamines; according to examples, products dyeing bluish red shades are obtained from mixts. of 1-amino-2-methylantraquinone with aniline and β -naphthylamine, respectively.

Dyes. BADISCH. Brit., 17,363, July 24, 1914. Leuco compds. of dyes are obtained in dry condition by spraying a paste, soln., or suspension thereof into a current of hot air; other substances such as molasses, dextrin, etc., may be mixed with the leuco compd. treated. According to an example, a paste of indigo white and molasses is employed; indigo-white derivs. or thioindigo white are also specified.

Monoazo dyes. BAYER & Co. Brit., 26,236, Nov. 15, 1913. Monoazo dyes are obtained by combining the diazo compds. of mononitroarylacyl or monoacylamino arylacyldiaminosulfonic or -carboxylic acids with pyrazolones or sulfonic or carboxylic acids thereof derived from aromatic aminothiazoles, and reducing or saponifying the

products; the same dyes are obtained by combining the diazo compds. of aromatic nitroaminosulfonic or -carboxylic acids, such as *p*-nitroaniline-*o*-sulfonic or -*o*-carboxylic acid, or aromatic monoacyldiaminosulfonic or -carboxylic acids, such as monoacyl-*p*-phenylenediaminesulfonic or -carboxylic acid, with the above mentioned pyrazolones, reducing or saponifying, introducing a nitroarylacyl group into the amino group, and finally reducing. The pyrazolone derivs. are obtained by diazotizing the aminothiazoles, reducing to give the corresponding hydrazines, and condensing these with acetoacetic or oxalacetic ester. Nitroarylacyldiaminosulfonic and -carboxylic acids are obtained by condensing equi-mol. parts of nitrobenzoyl chloride, and an aromatic diamino-sulfonic or -carboxylic acid in alk. or HOAc soln.

Secondary diazo dyes. CASSELLA & Co. Brit., 28,925, Dec. 15, 1913. The dyes are obtained by combining diazo compds. of the benzene or naphthalene series with cresidine, α -naphthylamine or its 6- or 7-sulfonic acids, rediazotizing and combining with an aminoaryl-8-hydroxy-1,2-naphthiminazolesulfonic acid. *m*-Aminophenyl-8-hydroxy-1,2-naphthiminazole-5-sulfonic acid is obtained from 1,2-diamino-8-hydroxy-naphthalene-5-sulfonic acid.

Pigments, anthraquinone derivatives. BAYER & Co. Brit., 17,743, July 27, 1914. Al lakes are prepd. from quinizarinsulfonic acids. *E. g.*, the Na salt of 1,4-dihydroxyanthraquinone-2-sulfonic acid is boiled with $Al_2(SO_4)_3$ soln., and the lake is pptd. by Na_2CO_3 ; the Na salt of 1,4-dihydroxyanthraquinone-5-sulfonic acid is boiled with $Al(OH)_3$ paste; in either example $BaCl_2$ may be added. 1,4-Dihydroxyanthraquinone-2-sulfonic acid is obtained by sulfonating 1-hydroxyanthraquinone, nitrating, reducing and replacing the amino by the OH group.

Pigments; anthraquinone derivatives. BAYER & Co. Brit., 17,744, July 27, 1914. Al lakes are obtained from 1-amino-4-hydroxyanthraquinonesulfonic acids. *E. g.*, the Na salt of 1-amino-4-hydroxyanthraquinone-3-sulfonic acid is boiled with $Al_2(SO_4)_3$ soln., and the lake is pptd. by Na_2CO_3 ; the Na salt of 1-amino-4-hydroxyanthraquinone-2-sulfonic acid is boiled with $Al(OH)_3$ paste; $BaCl_2$ may be added. 1-Amino-4-hydroxyanthraquinone-3-sulfonic acid is obtained by sulfonating 1-hydroxyanthraquinone, nitrating, and reducing. 1-Amino-4-hydroxyanthraquinone-2-sulfonic acid is obtained by heating 1-amino-2-bromo-4-hydroxyanthraquinone with Na_2SO_3 soln.

Alizarin. CHEM. FABRIK GRIESHEIM-ELEKTRO. Brit., 16,859, July 15, 1914. Alizarin is obtained by heating mesonitro derivs. of anthracene with alkalis; oxidizing agent, Na_2SO_3 , and $Ca(OH)_2$, are advantageously added.

Aminothiazolesulfonic acids. BAYER & Co. Brit., 6,644, Mar. 16, 1914. Aminothiazolemonosulfonic acids are obtained by baking dehydrothiotoluidine or homologs, or substitution products thereof, or the corresponding primuline compds. with 1 mol. part or more of H_2SO_4 , preferably *in vacuo*. Aminothiazoledisulfonic acids are obtained by baking the above specified aminothiazoles with 2 mol. parts or more of H_2SO_4 , preferably *in vacuo*, or by sulfonating the monosulfonic acids described above with fuming H_2SO_4 , or by baking the known monosulfonic acids of the aminothiazoles with 1 mol. part or more of H_2SO_4 , preferably *in vacuo*. Monoazo dyes are obtained by combining the diazo compds. of the aminothiazoledisulfonic acids described above with acetoacetic arylamides. Products are specified from: dehydrothiotoluidinedisulfonic acid and acetoacetic *o*-aniside; dehydrothio-*m*-xylidinedisulfonic acid and acetoacetic *m*-xylylide; acetoacetic chloroanilide, *p*-aniside, and cresidine, and primulinedisulfonic acid, are also specified as components. The products dye cotton greenish yellow shades.

Dyeing. J. BRANDWOOD, T. BRANDWOOD and E. BRANDWOOD. Brit., 17,219,

July 21, 1914. Reversal of the liquid current in a liquid circulation app., for dyeing or similarly treating textile in cop, cheese, or other compact form, is secured by the use in series of a centrifugal or turbine pump, a dyeing chamber, and a second similar pump, operating oppositely to the first; these pumps are driven alternately, the still pump opposing little resistance to the passage of the liquid.

Dyeing. CHEM. FABRIK GRIESHEIM-ELEKTRON. Brit., 17,272, July 21, 1914. Artificial silk is dyed by first impregnating it with a soln. of an arylide of 2,3-hydroxynaphthoic acid and then treating with a non-sulfonated diazo, diazoazo, or tetrazo compd.; the silk need not be dried between the two treatments. According to examples: viscose, Elberfeld, or Tubize silk is impregnated with a padding bath containing 2,3-hydroxynaphthoic anilide, NaOH lye, Na ricinoleate or the Na compd. of Turkey-red oil, and is then developed in a bath of diazotized *p*-nitro-*o*-toluidine or 4-amino-3,3'-dimethylazobenzene; Tubize silk is impregnated with a padding bath containing 2,3-hydroxynaphthoic *m*-nitroanilide, NaOH lye, Na ricinoleate or the Na compd. of Turkey-red oil, and HCHO, and is then developed in a bath of diazotized *m*-nitro-*o*-anisidine containing $\text{Al}_2(\text{SO}_4)_3$; viscose silk is impregnated with the padding bath of 2,3-hydroxynaphthoic anilide described above, and developed with a bath of tetrazotized dianisidine containing CuCl_2 , H_2CrO_4 , and $\text{Al}_2(\text{SO}_4)_3$.

Dyeing and otherwise treating textiles. BRADFORD DYERS' ASSN. and E. J. WILKINSON. Brit., 17,215, July 21, 1914. After passage through a treating liquid, fabrics, yarns, etc., are retained wholly within an enclosed space while being kept in motion, so that the liquid becomes uniformly diffused through the material. The space may be heated and freed from air by injection of steam. The invention is applicable to dyeing, malting, leaching, and mordanting.

Dyeing apparatus. UNIFORM DYEING MACHINE CO. Brit., 17,296, July 21, 1914. A dye-vat through which the liquor is caused to circulate alternately in reverse directions is divided into chambers, one of which is fitted with removable perforated shelves and with a liquid distributor below them, while the bottom of the other chamber is also connected to the liquid supply.

Dyeing and like apparatus. J., T., and E. BRANDWOOD. Brit., 17,355, July 22, 1914. Perforated beams or the like, upon which warps are treated with dyes or other liquids, and which are constructed with those parts that make contact with the warps of a material which is unaffected by the liquids used, are made with strong supporting Fe flanges which back the protective flange of Ni, Ni alloy, hard rubber, ebonite, etc., and which extend to the full diam. of the Ni, etc., or preferably beyond it.

Finishing fabrics. CASSELLA & CO. Brit., 17,318, July 21, 1914. In order to prevent fabrics or yarns dyed with vat colors from bleeding when washed in strongly alk. baths, a compd. which prevents the reduction of the vat colors to sol. compds. is added to the usual dextrin or glucose finish. Sulfates, chlorides, and nitrates of the heavy metals may be used for this purpose, also monochromates, dichromates, and bromates, or certain nitro products of organic compds. *E. g.*, 1 g. CuSO_4 and 3 g. $\text{K}_2\text{Cr}_2\text{O}_7$ may be added to each liter of the finish.

Scouring yarns. G. BAILEY. Brit., 16,629, July 13, 1914. In app. for scouring or treating yarns, etc., the series of endless tapes carrying the hanks, etc., are arranged so as to extend beyond the vat only after passing between squeezing rollers, and to be at other parts entirely within the vat. By this arrangement, the tapes are kept clean and do not carry liquor away from the vat.

Condensation products of oxazine dyes or their derivatives with phenols, amine aminophenols, aldehydes, ketones, and their derivatives. KATTUNDRUCKEREI HEUMANN & CIE and M. BATTEGAY. Ger., 284,877, Nov. 21, 1913. The reaction

products of the specified compds. are produced directly on the fiber, without previous sepn. An oxazine dye, especially the reaction product of nitrosodialkylaniline hydrochlorides with gallic acid or its derivs., dissolved or suspended, is mixed with phenols, amines, aminophenols, aldehydes, ketones, and their derivs. with Cr acetate or neutral chromate or even with tannin, the resulting product is applied to the fiber, and developed by heating. Suitable additions, such as NH_4Cl , soda, HOAc , HCOOH , bisulfite, or rongalite, are preferred for the reaction.

Chroming aniline black dyeings. J. P. BEMBERG, *AKT.-GES. Ger.*, 284,887, Sept. 23, 1913. Cf. *C. A.* 9, 864.

Fast color printing. BADISCHE. *Ger.*, 284,856, Oct. 20, 1912. Addition to 281,859 (*C. A.* 9, 2154). The printing color used is made of 300 parts of the Cr compd. obtained according to 282,987, 500 parts HOAc -starch-tragacanth thickening, 40 parts HCOOH , and 160 parts H_2O . The print is then dried and steamed for 5 mins., then rinsed with H_2O and finished in the usual manner. A reddish yellow print is obtained which is quite fast to soap, Cl and light. Instead of steaming the print, it may be treated with NH_4OH soln. which contains 10 cc. of 20% NH_3 per liter, for about 2 mins. at 50° , or it may be exposed to the action of NH_3 vapors.

Production of polychrome designs on paper. F. A. BAYER. *Ger.*, 284,469, Jan. 30, 1914. Addition to 283,690 (*C. A.* 9, 2599).

Preventing yellowing of textiles containing soap. R. WISS. *Ger.*, 284,852, Nov. 4, 1913. The soap contained in washed goods treated by finishing agents containing soap decomposes gradually, under the influence of air and heat, and the decompn. products color the material yellow, often with the development of an unpleasant odor. This condition may be obviated by employing, instead of the usual K or Na soap dressings, tech. pure NH_4 stearate or palmitate, to which may be made additions which do not render the material waterproof, so that absorbed substances can be removed by washing. Boric and perboric acids, NH_4 borate, NH_4 perborate, and other NH_4 persalts or peroxides are specified as suitable. These compds. whiten the material. The flexibility of the material is increased by the addition of vaseline. A temp. of about 35° should not be exceeded during drying, in order to avoid a complete decompn. of the NH_4 salts.

Imparting a silk-like luster to mercerized or unmercerized cotton. H. DUTSCHKE. *Ger.*, 285,023, Apr. 20, 1913. The process is applicable before or after mercerization, preferably after dyeing. The dyed material, wet or dry, is impregnated once or more with solns. of NaCl or NH_4OH , or with mixts. of these salts, and passed several times through a calender heated to 100 – 200° or higher. After the last passage through the calender the material is wound upon the drying or stretching machine. The luster is improved by another passage through a finishing calender heated to 150° . After the specified treatment the material may be allowed to remain for a day in cold or warm H_2O , weakly acidified, or ironed wet, without loss of sheen. Cf. *C. A.* 9, 1997.

26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN. *

Minium. JAROSLAV MILBAUER. Prague. *Chem. Ztg.* 39, 858–9(1915).—Earlier work (*C. A.* 3, 2617; 4, 28, 1434; 5, 1716; 6, 795; 7, 1587; 8, 2955) was done on pure material. The object of the present investigation was to show the influence of impurities usually found in commercial Pb (Ag, Bi, Zn, Fe, Sb, and Cu). In each case parallel expts. were made with pure PbO . A mixt. containing 3.2% Ag_2O gave at 300° a product with 27% Pb_3O_4 against 9% with the pure PbO . At higher temps.

the results were the same as with pure PbO . 0.6% and 1.0% Ag_2O gave similar results. The presence of Ag_2O did not injure the color. Bi_2O_3 in amts. of 0.02, 1.2 and 2.4% did not appreciably reduce the amt. of Pb_2O_4 , but gave a brown tint. The presence of 0.1-1.3% ZnO reduced the % Pb_2O_4 but did not affect the color. The action of Sb was similar to that of Zn , and small amts. did not affect the color. Fe and Cu did not act as catalyzers, and the presence of large amts. injured the color.

J. H. MOORE.

Paint. G. B. HECKEL. *Met. Chem. Eng.* 13, 806-11(1915).—This is a general article describing raw materials.

E. W. BOUGHTON.

The determination of methyl and ethyl alcohol in spirit varnishes. G. W. KNIGHT AND C. T. LINCOLN. *J. Ind. Eng. Chem.* 7, 837-43(1915).—A review of the literature is given. It is shown that the refractometer method of Leach and Lythgoe (*J. Am. Chem. Soc.* 27, 964) requires a modified method of calcn., owing to the difference in d. of MeOH and EtOH . In the presence of acetone, it is necessary to convert MeOH and EtOH into iodides by means of I and red P . The vol. of the mixed iodides obtained is noted and by means of a formula the % of MeOH and EtOH in the varnish is calcd. Details of procedure are given. K. and L. also recommend this method for the detn. of either MeOH or EtOH , when only one of the two is present, in the presence of acetone. A different formula is used for each case. MeOH is detected by Schiff's reagent after oxidation, with $\text{KMnO}_4 + \text{H}_2\text{SO}_4$ and EtOH by Schiff's reagent after oxidation with $\text{Br-H}_2\text{O}$.

E. W. BOUGHTON.

Isolation of the Central Powers and its effect upon the lacquer and drier industry. W. ESCH. Hamburg-Uhlenhorst. *Chem. Rev. Fett-Harz Ind.* 22, 87-90(1915).—Cellulose-pitch, Swedish wood pitch and cumaron resin (from coal-tar pitch) are now used as substitutes for rosin in Germany. Lack of S hindered the working of the sulfite pulp process, and the soda pulp process has partially replaced it. With the exception of very small quantities of Java copals (*via* Holland) no copals are entering Germany, nor are dammar, dragon's blood, euphorbium, mastic, sandarac, shellac, acaroid, japan, copaiba, gurjun, Canada balsam, caoutchouc and gutta-percha. As a substitute for copals and shellac the condensation products, such as are made from phenol and formaldehyde, are considered. A new process by the Wenjact Gesellschaft in Hamburg (patent applied for) produces a condensation product which has the consistency of gutta-percha and which is sol. in alc.; this soln. gives an excellent hard coating after heating to 85° . Some expts. with this new lacquer are described. P. ESCHER.

Quantitative determination of adulteration in Chinese wood oil. J. C. BRIER. *J. Ind. Eng. Chem.* 7, 953-7(1915).—The effect of different oils on the spectrum of the Chinese wood oil was detd. and the point at which the spectrum changes is termed the turning point; this requires 14.5-17%. If the adulterating oil is known, very accurate results can be obtained. The addition of 15% of linseed oil is necessary to reach the turning point. To det. the % it is necessary to find out how much adulterant must be added before the turning point is reached, then by subtracting the amt. from 15.5 the amt. present in the oil is obtained.

E. SCHERUBEL.

Composition of wood turpentine. M. ADAMS. *J. Ind. Eng. Chem.* 7, 957-60(1915).—Wood turpentines from 3 sources were investigated. The wood was heated in a retort under diminished pressure and the distillate fractionated. The single leaf nut pine (*P. monophylla*) yielded a turpentine containing α -pinene, β -pinene and cadinene. The results indicated that the wood turpentine is almost identical with the pure "gum" spirits. The volatile oil from Jeffrey pine (*P. jeffreyi*) contained 95% of normal heptane. The presence of citronellol was indicated but not confirmed. Yellow pine (*P. ponderosa*) yielded the oil containing α -pinene, β -pinene and

limonene. This oil contained more of the low-boiling and less of the high-boiling fractions than that obtained from the oleoresin. A. concludes that with each variety of wood the volatile oil obtained by distg. the wood under diminished pressure is similar to that obtained from the oleoresin.

E. W. BOUGHTON.

Autooxidation of rosin. W. FAHRION. *Chem. Rev. Fett.-Harz. Ind.* 22, 97-8 (1915).—Paul's work on rosin (*C. A.* 8, 2626, 3379; 9, 972, 2715, 3135) is severely criticized as being mere hypotheses built on scanty expts.

P. ESCHER.

Experiments with "venturpech" in experimental acetic acid manufacture. H. WÜSTENFELD. *Deut. Essigind.* 18, 491-3.—"Ventur" is a new acid-resistant material consisting of pitch, paraffin and linseed oil for impregnating tubs, vats and also for painting walls. It has been successfully used for impregnating vats in vinegar manuf.

H. A. PIPER.

The use of ammonium hydroxide for the extraction of rosin from wood (BENSON)

22.

Pigment from blast furnace dust. F. ORTH. U. S., 1,161,790, Nov. 23. Blast furnace flue dust which has accumulated during several hrs. run of the furnace is collected and thoroughly mixed to secure uniformity of color and is ground to form a fine pigment for use in brick, etc. About 70% of Fe oxide is usually present in the dust.

Coating iron or steel to prevent rusting. D. F. COMSTOCK. U. S., 1,159,748, Nov. 9. The surface of the metal is treated with an alc. soln. of caustic alkali, exposed to the air until the alkali is converted into carbonate and then covered with a layer of shellac.

Rendering pyroxylin colloidal. H. W. MATHERSON. U. S., 1,161,063, Nov. 23. Phenyl benzoate is used with about 3 times its wt. of cellulose nitrate, a homogeneous product being formed by use of a volatile solvent such as EtOH, acetone and C₆H₆, with or without camphor.

Varnish-reviving and polishing composition. G. S. A. CASSIMUS. U. S., 1,161,187, Nov. 23. SiO₂ free from grit 48, is mixed with soap 6, MgO 3, boiled linseed oil 44 and H₂O 120 parts.

Paint- and varnish-remover. C. ELLIS. U. S., 1,160,394, Nov. 16. The mixt. is formed of PhOH 20 gals., C₆H₆ 13 gals., denatured alc. 20 gals., wood flour 10 lbs., ceresin wax 5 lbs., and NaOH 2-6 lbs. Pine oil, MgO and Turkey-red oil may also be included in similar mixts.

Marking ink for transfer of embroidery designs. J. MOSSMAN. U. S., 1,159,857, Nov. 9. Turpentine 1, beeswax 8, linseed oil 6 and coloring material 4 parts are used in making up the ink.

Resin size for paper manufacture. B. KNIFFLER and W. A. OPPEN. U. S., 1,160,906, Nov. 16. The size is treated with steam under pressure in a closed vessel and when thoroughly heated is discharged in a thin stream into a body of H₂O in a vat. A homogeneous liquor is thus produced which retains the size in suspension.

White lead. F. H. SHARPE. *Brit.*, 17,579, July 24, 1914. In carbonating a mixt. of PbO.H₂O and an assisting agent such as HOAc, the carbonating gas is delivered against the bottom of the carbonating vessel so as to sweep the PbO upwards to bring it within the field of action of other streams of the gas issuing from pipes so curved that the gas imparts an upwardly whirling motion to the oxide.

Japanning. K. MIYAZAKI. *Brit.*, 16,743, July 14, 1914. Sn plate for canning purposes is coated with a lacquer obtained from *Rhus vernicifera* mixed with shellac,

the coated sheets being allowed to dry in a damp atm. and then heated to 120-180°. The raw lacquer is first refined, as by heating with stirring and finally filtering, and a small quantity of shellac dissolved, as in vegetable oil, is added. The mixt. is applied while the plate is hot. The plate is preferably first cleaned by treatment with dild. alk. soln. and then with acid, each soaked into a piece of cloth, and is finally dried by alc.

Metal lithographic plates. J. GRASS. Brit., 1,769, Jan. 22, 1914. In mfg. plates for direct or offset printing of the kind in which an intaglio printing surface is produced by printing photographically through a positive transparency on a sensitized colloid film, coating the plate, and etching the plate through the exposed film, a mat varnish, which is insol. in H₂O or lithographic ink, such as celluloid varnish, is applied to the intaglio recesses to enable the plate to carry more ink.

Anti-rust paint. H. HOWARD. Ger., 284,637, Sept. 4, 1913. See Fr., 462,148 (C. A. 8, 2498).

27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

New method for determining the melting point of fats. R. ROMARNELLI. *Pharmaceutisk Revy* 1915, No. 28; through *Seifensieder-Ztg.* 42, 830(1915).—The app. consists of a wide-neck 250 cc. flask having a cork contg. a thermometer to which a Pt wire is attached, having its free end in the form of an 8 to 9 mm. loop in a vertical position at the same height as the Hg bulb. To make a detn. the fat is melted and when nearly ready to solidify the Pt loop is introduced parallel to the surface and quickly withdrawn. After cooling 1 hr. the wire is fastened to the thermometer and the flask heated over an asbestos plate. When the m. p. is neared the periphery of the fat layer becomes transparent and the film drops. The temp. is read at this moment.

E. SCHERUBEL.

The coloring materials of fatty substances. H. DUBOVITZ. *Mat. grasses* 8, 4326-7(1915).—The coloring matters resemble fatty acids chemically; they dissolve in the same solvents and are saponified by alkalies. However, they can not be pptd. as easily as fats in general by an alkaline salt soln. containing glycerol. Their b. ps. are higher than those of the fatty acids, which appears to be the reason why colored fatty acids give a colorless distillate.

E. J. KELLEY.

Lubrication of bearings and cylinders. F. L. FAIRBANKS. *Power* 42, 805-8 (1915).—An address delivered at Worcester Polytechn. Inst.

C. G. F.

Studies on the hydrogenation of fats and oils. JAMES DEWAR AND ADOLPH LIEBMANN. *Mat. grasses* 8, 4377-9(1915).—The authors describe methods by which hydrogenation may be accomplished. These methods consist generally in treating the liquid fats and oils with H in the presence of mixts. of hydroxides, oxides, or carbonates of two or more catalytic metals such as Ni, Co, Cu, Pd, Pt and Au.

E. J. KELLEY.

Utilization of fatty acids. BERGO. *Seifensieder-Ztg.* 42, 865-7(1915).—Discussion of the handling and sapon. of fatty acids.

E. SCHERUBEL.

Sunflower seed oil. ANON. *Seifensieder-Ztg.* 42, 886(1915).—Constants and uses are given.

E. SCHERUBEL.

Effect of free fatty acids upon flash and fire points of animal fats and oils. A. LOWENSTEIN AND J. J. VOLLERTSEN. *J. Ind. Eng. Chem.* 7, 850(1915).—The presence of free fatty acids depresses the flash and fire point of animal fats owing to the fact that these points are lower for the fatty acids than for the glycerides. E. SCHERUBEL.

Recovery and purification of by-product fats and oils. A. LÖB. *Seifensieder-Ztg.* 42, 907-9(1915).—Discussion of well known processes. E. SCHERUBEL.

Bleaching and refining of dark fats and oils. C. H. KEUTGEN. *Seifenfabr.* 35, 893-4, 909-12(1915).—Discussion of common methods. E. SCHERUBEL.

Hydrocarbons in fish-liver oils. HUGO MASTBAUM. Lisbon. *Chem. Ztg.* 39, 889(1915).—A shipment of oil to London was condemned as adulterated with mineral oil. Part of the lot remaining in Lisbon was tested by M. and showed: d_{15}^4 0.869, sapon. number 24.15, acid number 1.46, unsaponifiable oil by direct detn. 83%. Another cargo gave 0.863, 18.1 and 1.62, resp. Two species of fresh fish from the Moroccan coast were then opened and the oil from the livers tested. Consts. for oil from *Centrophorus granulosus* and *Scymnus lichia*, resp., were d_{15}^4 0.8637, 0.8711, butyro-refractometer at 25° 102, 93, polarization in 200 mm. tube -0.3° , -2.33° , solidifying point still fluid at -7° , became turbid at -7° , sapon. number 15.4, 36.7, acid calcd. as oil acid 0.097, 0.165. The unsapon. portion of the oil from *Scymnus lichia* began to boil at 205°, and about 70% had distd. at 330°. The residue was a dark, paraffin-like mass. Thus, liver oils from certain fish contain 80-90% of oil with the characteristics of mineral oil, a fact which seems to support the theory of the animal origin of petroleum.

J. H. MOORE.

Determination of ricinic acid in oil preparations. F. ERBAN. Vienna. *Seifenfabr.* 35, 846-8, 861-4(1915); cf. C. A. 8, 2818; 9, 1255, 1400.—A complete analysis of a highly sulfonated Turkey red oil made from 50 g. of castor oil and 17.5 g. concd. H_2SO_4 is described in detail, including detns. of neutral fat, org. and inorg. S, total fat, sol. fatty acids and their titration, and glycerol. Calcns. are given showing in tabulated form; neutral fat, ricinic and diricinic acid, lactide, diglyceride, org. S and distribution of the KOH. E. SCHERUBEL.

Oils extracted by carbon disulfide. G. BOUCHARD. *Mat. grasses* 8, 4371-3, 4387-9, 4403-5(1915).—B. shows the superiority of CS_2 over other solvents and gives a description of various oils and their properties. EDWARD J. KELLEY.

Significance of Barretrapps reaction for the fat and soap industry. W. SCHRAUTH. *Seifenfabr.* 35, 877-9(1915).—According to Barretrapp's reaction, oleic acid is easily changed to palmitic by melting at about 300° with excess KOH, as follows: $C_{17}H_{33}COOH + 2 KOH = C_{16}H_{31}COOK + CH_3COOK + H_2$. Owing to high cost and danger from H_2 the process was never taken up to any extent. S. contends that at the present time these objections should have no weight as the danger can be overcome and oleic acid can be replaced by cheaper fatty acids. Palmitic acid, produced by the acidification of the final product in this process, requires distn. to improve the color. If fish oil is used the yield is 85%, the loss consists of 10-12% as acetic acid and 3-5% distn. residue. The technical operation of the process can be effected with NaOH in a 50% soln. in autoclaves holding 5000 liters. The temp. necessary is 200° which is increased to 260° during the course of 6 hrs. The pressure is not allowed to go over 10 atm. The production can be worked up as a salable soap or decompd. with acid and distd. The working of this process would lessen the demand for coconut and palm kernel oils. E. SCHERUBEL.

Recovery of fat for the soap industry from waters carrying waste greases. P. M. GREMPF. *Seifensieder-Ztg.* 42, 846-67-8(1915).—Discussion of recovery of fats from catch basins and sewage waters. This recovery only pays where the vol. handled is large. E. SCHERUBEL.

Determination of the fatty acids in soaps. A. A. BESSON. *Mat. grasses* 8, 4315-16(1915).—The author finds that: (1) ethyl ether is preferable to petroleum ether; (2) the fatty acids need not be changed into salts; they may be weighed themselves, even in the presence of volatile fatty acids. Co and Ni oxides are es-

and fats are then sepd. from the aq. soln. and the latter is heated to ppt. CaCO_3 (or CaSO_3) and the remaining aq. soln. is evapd. to recover NiCl_2 , glycerol, etc.

Washing and bleaching composition. J. BARRINGTON. U. S., 1,160,563, Nov. 16. The compn. is formed of Na perborate 20, borax 40 and NaH_2PO_4 40 parts. Cotton is bleached by boiling in H_2O containing small amts. of this mixt. and of soap.

The hydrogenation or dehydrogenation of compounds containing carbon. BADISCHE. Brit., 2,306, Jan. 28, 1914. The process is effected in the presence of a catalyst consisting of Fe, Ni, Co, or Cu, intimately mixed with 1 or more of the following "promoters:" oxides or O-containing salts of earth metals, rare-earth metals, Be, Mg, Mn, U, V, Nb, Ta, Cr, Ti, or B; difficultly sol. phosphates, molybdates, tungstates, or selenates, of the alk. earths or of Li, or O-containing reduction products of these compds. The intimate mixt. of the catalytic metal with the promoter may be obtained by pptg. mixts. of the hydroxides, oxides, or carbonates, from solns. of the salts, or by fusing mixts. of salts such as the nitrites, or by mechanical operations, such as grinding or kneading the components together; the catalytic metal compd. is reduced to the metallic state, preferably by means of H at as low a temp. as possible, any excess of H being removed after the reduction by means of an indifferent gas, such as CO_2 . The catalytic metal may be prepd. from carbonaceous salts, such as carbonates or formates, or the metal may be employed in a state of fine division, or in the form of netting, wool, sheets, etc. There may be added to the catalytic mixts., alkali compds., such as NaOH, or inorganic or organic substances which act as carriers or binding agents, or increase the porosity of the mass, *e. g.*, asbestos, charcoal, or pumice. The presence of contact poisons, such as Cl, S, As, and Pb, should be avoided, although in some cases O salts containing these elements, *e. g.*, basic Al-sulfate, may be used. The proportion of the promoter in the catalytic mixt. may be as small as 1% or less. The catalytic mixts. may be employed, *e. g.*, in the hydrogenation of fats or fatty acids, the conversion of phenol into cyclohexanol, the reduction of nitrobenzene to aniline, and the conversion of C oxides into hydrocarbons; these processes may be effected under ordinary or increased pressure. According to examples, a soln. containing Ni and Be nitrates is pptd. with NaOH, the NiO is reduced by means of a mixt. of CO and H, or H alone, and the product is employed for the conversion of a mixt. of CO and H into CH_4 ; solns. containing $\text{Ni}(\text{NO}_3)_2$ and Zr or Th nitrate may be similarly treated; Ni oxalate is mixed with $\text{Al}(\text{NO}_3)_3$ soln., and the mixt. is dried and reduced by H and employed in the hydrogenation of fish oil; Ce nitrate or Ce NH_4 nitrate may replace the $\text{Al}(\text{NO}_3)_3$; a soln. containing Ni and Al nitrates is pptd. by K_2CO_3 , and the product is reduced by H and employed in the hydrogenation of soy-bean oil in an autoclave under pressure; $\text{Fe}(\text{NO}_3)_3$ may be employed instead of $\text{Ni}(\text{NO}_3)_2$; a mixt. of Ni and Mg hydroxides or carbonates is converted into formates by treatment with HCOOH , and the product is reduced by H and employed in the hydrogenation of olive oil; carriers, such as pieces of clay, may be soaked in a melt or soln. of Ni salts, such as ammoniacal Ni formate, or carbonate, together with the salt of the promoter, and treated similarly; spheres, rolls, etc., of Ni wire netting are moistened with $\text{Al}(\text{NO}_3)_3$ soln., dried, treated with H, and employed in the hydrogenation of linseed oil; a soln. of $\text{Ni}(\text{NO}_3)_2$ and Ti lactate is pptd. by NaOH, and the product is reduced by H and employed in the hydrogenation of cotton-seed oil, the hydrogenation being effected if desired under a pressure of, say, 100 atms.; NiCO_3 is mixed with NH_4 or K borate soln., and the mass is suitably shaped, dried, reduced, and employed in the hydrogenation of oils or fats; Cr_2O_3 may be obtained for use as a promoter by pptn. from $\text{Cr}(\text{NO}_3)_3$ or sol. chromates; the oxide or carbonate of the catalytic metal may be mixed with solid or dissolved H_3BO_3 , and the product be heated and reduced; a salt of the catalytic metal, *e. g.*, the nitrate, may be

mixed with a borate of the same or another metal, and the mixt. be calcined and reduced; solns. of K aluminate, $\text{Ni}(\text{NO}_3)_2$, $\text{Ca}(\text{NO}_3)_2$, and Na_2CO_3 are mixed, the ppt. is dried and reduced; NiCO_3 is mixed with solns. of $\text{Mg}(\text{NO}_3)_2$, $(\text{NH}_4)_2\text{HPO}_4$, and NaOH , the ppt. is dried and reduced; the 2 mixts. last described may be used in the hydrogenation of oil resulting from cracking petroleum residues, the hydrogenation being effected at 100° under a pressure of 80 atms.; Ca vanadate, BaCrO_4 , Al borate, Ba tungstate, or Li_2HPO_4 , or the reduction products of these compds., may also be used as promoters; a soln. of Ni and Mn or Cr nitrates is pptd. by Na_2CO_3 , and the product is reduced by H and may be employed in the hydrogenation of pig-nut oil or soy-bean oil, resp.; NiCO_3 , NH_4 tungstate soln., and $\text{Ba}(\text{NO}_3)_2$ soln. are mixed, and the product is reduced and may be employed for hydrogenizing sesame oil; NiCO_3 is mixed with $\text{Ca}(\text{NO}_3)_2$ and $(\text{NH}_4)_2\text{HPO}_4$ solns., and the product is reduced and may be used for hydrogenizing fish oil; NiCO_3 is mixed with $\text{Sr}(\text{NO}_3)_2$ and NH_4 selenite solns., and the product is reduced and used for hydrogenizing cotton-seed oil; when Al_2O_3 is used as the promoter, it may be obtained by heating the acetate in the presence of the catalytic metal or compd. thereof.

Decomposing fats into fatty acids and glycerol. AKT.-GES. ZUR ERZEUG & ANWEND V. NAPHTHA-SULFOSAUREN, "KONTAKT." Brit., 17,148, July 20, 1914. Fats are hydrolyzed by means of sulfonic acids produced from paraffin or mineral oils, such as solar, paraffin, and anthracene oils, obtained from the tar of lignite, coal, peat, or bituminous minerals. The oil is treated with fuming H_2SO_4 , and the sulfonic acid is dissolved out from the upper layer by dil. alc.

Sulfonated fats or oils. I. LEVINSTEIN and LEVINSTEIN, LTD. Brit., 16,890, July 16, 1914. Hydrogenated saponifiable fats or oils are sulfonated by melting, cooling, and treating with H_2SO_4 until a sample gives an emulsion with hot H_2O , or a washed sample practically dissolves in ammoniacal H_2O ; the products are poured into warm salt soln., and purified by washing with salt H_2O or by neutralization of the H_2SO_4 with alkali. According to an example, hardened linseed oil is treated; hardened fish oil is also specified. The products, when mixed with waxes, oils, fats, etc., give compns. sol., miscible, or emulsifiable in H_2O ; according to an example, sulfonated hardened linseed oil is mixed with paraffin wax. Mixts. of hardened oils with oils or greases may also be sulfonated.

Lubricants. S. H. Blichfeldt. Brit., 17,411, July 22, 1914. A lubricant consists of such an emulsion of 5-25% H_2O or aq. soln. in 95-75% of oil or fat that the aq. particles have a diam. of 0.001 mm. or less. In an example, 15 parts of a 10% soln. of soap are emulsified in 85 parts of engine oil.

Soaps. I. LEISER. Brit., 17,461, July 23, 1914. Amber, as powder or in soln., as in alc. or CHCl_3 , or in both forms, is added to soap.

Perforations in straining walls of oil presses. HARBURGER EISEN-UND BRONZE-WERKE AKT.-GES. Ger., 284,522, Dec. 30, 1913. Each group of finely perforated sections is mounted in a larger opening.

Composite bars of soap. H. SCHWARZKOPF. Ger., 284,622, Feb. 18, 1914. App. for forming a hollow bar of soap and imbedding therein a soap core.

28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

The Belgian sugar industry before and during the war. ANON. *Chem. Ztg.* 39, 865-6(1915).—Statistics for the years 1893-1915 are given. J. H. MOORE.

Plant colloids. V. The soluble starches. M. SAMRČ AND S. JENCIC. *Kolloid-chem. Beihefte* 7, 137-71(1915); cf. *C. A.* 9, 468.—Previous expts. on the prepn. of soluble starches and the methods used to investigate starch solns. are reviewed. Soluble starch was prepd. by the methods suggested by different authors and the physico-chem. properties studied. It was found that in most of the cases the size of the mol. was reduced but that in some cases the mol. was not broken down. Most of the forms of soluble starch did not contain P. Detns. of the osmotic pressure and the elec. cond. of solns. of soluble starches which had stood for some time showed that in aging the changes which take place in the starch are a continuation of the changes which took place in converting the starch from insoluble to soluble. The decidedly different results obtained in the physico-chem. investigations of different soluble starches show that the term "soluble starch" is indefinite and does not adequately define the substance.
W. F. ZIMMERLI.

Purifying starch. L. P. BAUER. U. S., 1,161,826, Nov. 30. A deep body of starch in aq. suspension containing impurities lighter than starch is gently agitated below the surface to permit settling from the upper portion but maintain suspension of the solids in the lower portion of the body and permit the lighter impurities gradually to rise to the upper part from which they are led off, the denser suspension of purified starch being withdrawn from the bottom.

Apparatus for dextrinizing starch by treatment with steam and acid. A. W. H. LENDERS. U. S., 1,159,591, Nov. 9.

Dextrinizing starch. A. W. H. LENDERS. U. S., 1,159,592, Nov. 9. A batch of pulverized starch is fed gradually into a dextrinizing vessel while acid is added to it, forming a uniform mixt. Then the mixt. is agitated and heated in the vessel until the desired degree of conversion is effected. The heating is then discontinued and a cooling material brought into contact with the vessel, to stop the conversion and insure uniformity of the product.

Sugar. J. F. P. KESTNER. Brit., 17,010, July 17, 1914. "Aréado" or finely cryst. sugar is produced by causing melted sugar containing about 5% of H_2O to flow in a thin layer on an approx. horizontal vibrating surface, such as a table, endless band, or Kreiss jerking conveyer.

Treating sugar cane. T. LEE. Brit., 17,834, July 28, 1914. The prepn. of paper stock from the moist woody residues from the milling of sugar cane is made possible by eliminating the outer skin or rind. The bagasse is partly dried, preferably by agitation in a current of heated gases, then reduced by a shredding or picking process, preferably in a Williams' pulverizer. The product is then screened by vibrating screens of varying mesh; the granular pith passes through a fine screen while a coarser screen retains the strips of rind or outer skin and allows the fiber to be used for paper stock to pass through. This material is washed and then digested in alkali. The washings of the fiber are used for the maceration between the mills, and the sugar is thus conserved. The granular pith and the strips or pieces of rind or outer skin are used for fuel.

Starching preparations. E. M. NEWBERRY and E. A. SIMPSON. Brit., 16,774, July 14, 1914. A substitute for laundry starch consists of gelatin, borax, white wax, and formalin, substitutes for the wax being spermaceti or Castile soap. In an example, gelatin is soaked in cold H_2O , boiling H_2O is poured over the softened product, and the whole gently boiled. Borax, white wax, and $HCHO$ are then added in succession, and the product poured into molds, where it cools to a stiff jelly. Coloring matters may be added. The product is dissolved in H_2O for use on linen, muslins, etc.

29. LEATHER AND GLUE.

LLOYD BALDERSTON.

The influence of the method of subdivision of leather on the results of analysis. R. LAUFFMANN. *Collegium* 1915, 366-72; see C. A. 9, 2722. E. H.

The relation between the price and analysis of tanning materials. JOHN R. BLOCKEY. *Shoe and Leather Rep.* 120, No. 3, 25-7; No. 4, 105(1915).—Two materials costing the same amt. per unit of tan per ton, by analysis, may give quite different values in practice. These differences arise from the fact that analysis is made under conditions quite different from those which obtain in practice. The av. liquor in practical sole leather tanning is more than ten times as strong as the liquor used for analysis by the official methods of both the I. A. L. T. C. and the A. L. C. A. At the low concn. of the analysis there will be a great proportion of sol. matter which is not sol. at the relatively high concn. of the tanning liquor. In lab. analysis the ext. is dissolved with boiling water whereas in tannery practice it is common to add the cold ext. to the cold liquor, thus throwing out of soln. a considerable amt. of material which would otherwise be sol. and capable of being utilized. However, recent research points to the fact that such semi-sol. or insol. products have actual tanning value, especially in the case of quebracho ext. or gambier. Sommerhoff has shown that leather may be produced by using only materials usually reckoned as insol. The amt. of matter which can be extd. by water in analysis but which cannot be so extd. in practice may be considerable, due to the fineness of division of the material and also to the question of color. A clear liquor made from almost any tanning material will gradually deposit insol. matter known as "bloom." Much of this is deposited in the liquor or on the surface of the leather and is lost. In analysis, there is always an excess of hide, while in practice the tannin is always in excess. The leather produced in analysis consists of a large excess of hide powder, a small proportion of tannin matter, and no free sol. matter. Real leather consists of about equal proportions of hide substance and combined tannin, together with much uncombined matter, both tannins and nontannins. The analysis of a heavily tanned sole leather shows that nearly half of the "matters sol. in water" are non-tannins. These may not improve the quality of the leather, but they give weight and should be taken into account when considering the price of the material. In analysis the liquors are used before fermentation sets in, but in practice acids are formed in the fermentation of the tan liquors which may make possible the absorption of some of the nontannins, but, on the other hand, may cause the loss of tannin. This loss varies with the different materials and should be considered in dealing with the price of a raw material. In analysis, although the material is dissolved at a boiling temp., the liquor is cooled to atmospheric temp. before analysis. This is not universal in practical tanning, for some liquors are often used at a much higher temp., which would have an appreciable influence on the amt. of insol. matter. In analysis, materials are analyzed separately, while in practice they are almost invariably blended. This may make tannins of nontannins, or the reverse. It is known to render some insol. matter sol. in the blending of neradol with quebracho. J. S. ROGERS.

Oils used in leather manufacture. Simple tests to determine purity. F. I. C. *Leather World* 7, 370-1, 551(1915).—A general article describing the manuf. and purifications of oils for this purpose and tests for detg. their purity. J. S. ROGERS.

The presence of alkali in fat liquors. *Shoe and Leather Rep.* 120, No. 4, 105 (1915).—Most fat liquors are a mixt. of fat and oil. The soap emulsifies the oil so that it penetrates the leather thoroughly. It also helps lubricate and nourish the fibers, and it gives a feeling of fulness to the leather. The addition of alkali renders the emulsification of the oil easier, and, in the case of chrome-tanned leather, neutralizes

any free acid which may be present. This acid would decompose the fat liquor by curdling the soap, which would either prevent the penetration of the fat liquor, or cause a sticky surface which could not be glazed. If too much alkali is present, it will saponify the oil, particularly if boiled.

J. S. ROGERS.

What loosens the hair in liming hides? An unsettled question. HUGH G. BENNETT. *Shoe and Leather Rep.* 119, No. 13, 31-3(1915); *J. Am. Leather Chem. Assoc.* 10, 569-73(1915).—The author's opinion is that in liming hides the hair is loosened almost entirely by the chem. action of enzymes which are secreted by bacteria which feed on organic matter obtained from the gelatinous and albuminous matters of the hide. These enzymes dissolve the softer keratins and hair roots. This enzyme action is probably facilitated by the chem. action of lime which softens but has very little solvent effect. If the keratinous matters yield any S to the liquor, sulphhydrate of lime will be formed; this will have a very slight but direct chem. solvent effect.

J. S. ROGERS.

Tanning hair skins. Full description of processes including alum, chrome, neradol, combination and seal oil. ANON. *Shoe and Leather Rep.* 119, No. 13, 42-3, 120, No. 1, 65-7(1915).—Skins to be tanned with the hair on should be sent to the tanner immediately, or should be cured by washing and thoroughly salting the flesh side, or by washing and stretching to dry in the shade. The tanner washes off the salt if the skin has been salted, or soaks it if it has been dried. A weak alkali or acid soln. is better than clear water for soaking as the skin will then soften without decompn. A good soln. may be made with 1 lb. NaOH, or 2 lbs. borax, or 1 to 2 lbs. formic acid in 100 gals. water. Sodium sulfide would loosen the hair. When the skin is soft and clean, the lumps of fat and flesh must be removed with a sharp knife. Then the hair and skin should be freed from grease by rubbing with a warm, strong soln. of soft soap. After being well washed with clean water, the skin is ready for tanning. For alum tanning, the skins are moved up and down in a soln. of 5 lbs. alum and 6 lbs. common salt to 12 gals. hot water ($\frac{1}{2}$ lb. borax may be added to cut grease if necessary). After 24 hrs. the skins are removed and the flesh side covered with a paste. For 100 lbs. of skins, sufficient paste may be made from 4 lbs. alum, 3 lbs. salt, 4 lbs. flour, 1 lb. egg yolk, and 1 lb. olive oil. This should remain for a long time to make the tannage permanent. The leather will be white and flexible and the color of the hair unaltered. The one-bath chrome process may be used. For 100 lbs. skins, dissolve 10 lbs. chrome alum in 8 gals. cold water (some use hot water), and 3 lbs. washing soda in 1 gal. warm water. The soda soln. should be poured into the chrome alum soln. gradually while stirring. The concn. of the liquor should be such that it will be completely expended in the method of working. After being tanned the skins should be well washed and the free acid neutralized by borax (2 or 3% borax reckoned on the wet wt. of skins). A fat liquor should be applied to allow the skin to dry soft and flexible. A good fat liquor sufficient for 300 to 400 lbs. skins may be made from 1 gal. castor oil, $3\frac{1}{2}$ lbs. soft soap, and $\frac{1}{2}$ lb. egg yolk. Neradol tannage is rapid and permanent and produces a white leather which is soft and mellow and very resistant to water. It is less durable and less resistant to water than chrome leather. H. Brumwell in the *Leather Trades Year Book* for 1915 gives details for neradol tannage for furs. Professional fur dressers combine mineral and vegetable tannages. The resulting leather is soft, flexible and durable. M. Lamb's paste formula is: 5 lbs. $Al_2(SO_4)_3$, 5 lbs. common salt, $\frac{1}{2}$ lb. rye flour, and 10 gals. water. Glycerol or oil may be added. The flesh side of the skin is covered with $\frac{1}{8}$ in. of this paste, allowed to remain wet for some time by placing the flesh sides together, and then slowly dried. In the Furrier's Dress Process the goods is first freed from superfluous moisture and the flesh side is then rubbed with a good quality of seal oil. The skins are folded,

flesh inside, and placed in a wooden tub where they are tramped upon by a workman with bare feet, left for several hours, and the process repeated. The temp. should not exceed 38° to 40°. When thoroughly tanned, the skins are given a weak alk. bath and subsequently dried.

J. S. ROGERS.

Tanning materials in South Africa. EUGENE M. LAMB. *Commerce Reports* No. 254, 428-9(1915).—Wattle, sumac, "elandsboontjes" (*Elephantorrhiza burchellii*, leguminosae), bastard sumac and mangrove can all be produced on a commercial scale in S. Africa. A new extn. process in use there consists in crushing the bark and then passing it through a series of heavy-pressure bronze rollers after moistening it with warm water or with water and alc.

E. H.

Oriental manufacture of gambier. ALEXANDER T. HOUGH. *Leather Trades Rev.* 48, 512-4, 580-1(1915).—The author visited a gambier plantation in the Malay States operated by Chinese. The gambier branches are chopped at the factory into pieces about 5 in. long and are boiled twice. The liquor from the second boiling is used on fresh cuttings which are boiled until sufficiently concd. (about 10 hrs.). The leaves are then forked out and the liquor dipped out and strained into 6 tubs holding about 3 gals. each. The 18 gals. are claimed to yield 88 lbs. gambier. To each tub is added 1.25 lbs. rice meal to thicken the liquor. When cool and pasty, the 6 tubs are emptied into a bottomless box fitted over a perforated board covered with sacking. Considerable tannin filters through and is lost. The firm block consists of coagulated rice dust, crystd. catechol, and as much tannin as it can hold. This is cut into cubes about 1.5 in. square which are spread out for 7 to 9 days on the beams in the roof of the factory, the heat and smoke from the boilers facilitating the drying. The product is not exported to Europe from Borneo because greater profit can be made by selling it to the East Indian natives for chewing. The author collected samples for analysis and presents the results in tabulated form. The tannin content of true gambier leaf is 5.5%, of spent gambier leaf 2.6%, of wild gambier leaf 5.7%, of liquor before adding rice 13.7%, of liquor straining through mold 7.5% and of the final product, cube gambier, 35%. It is evident that over 50% of the total available tannin is lost. However, the Chinese product, "liquor before adding rice," if calcd. on the same moisture basis, is almost identical with that of the European manufacturer's plantation gambier as produced in Sumatra. The fat and a considerable proportion of the N are introduced in the rice dust. The insolubles in cube gambier are practically all due to the albuminoids present in the added rice meal. The mellowing properties of gambier are probably also due to the rice meal, as fermentation is caused by the amyloids, and the farinaceous matters are in current use in the production of the softer leathers. Several different plants are called "wild gambier." The sample analyzed was identified as *Uncaria*.

J. S. ROGERS.

The use of mimosa or wattle bark. F. T. EDWARDS. *Leather World* 6, 776(1914); 7, 15-6, 491-2, 550(1915).—The use of mimosa bark in the United Kingdom has been gradually extended. A special advantage is that it is suitable for both light and heavy leathers. The black wattle (*Acacia binervata*) is indigenous to Australia but has been grown in Africa. The green wattle (*Acacia mollissima*) is the most important. The golden wattle in S. Australia is very strong in tannin but is not hardy. Golden wattle in N. S. Wales contains less tannin. Varieties of mimosa in S. America are mostly inferior in tannin strength. The black and green varieties contain about equal percentages of tannin, but the black is said to yield more bark to the acre, while the green is hardier and will withstand frost. Mimosa bark is one of the cheapest tanning materials, the av. strength being 32% tannin and the av. price \$45 per ton. The cheapness is accentuated when the questions of practical extn. and utilization of available tannin are considered. (1) The tanning matters are sol. not only at the low concn.

of analysis but also at the high concn. of practice. (2) At a temp. of 30°, more than 90% of the total available tannin is extd. This is an exception to the rule that a higher temp. signifies a higher extn. (3) Shredded mimosa bark as put on the market is so finely divided that there need be little difference in analytical and practical results in this respect. (4) Mimosa bark contains no pyrogallol tannin and has been found by Paessler to lose less by deposition than any other material. Mimosa bark is easily one of the strongest raw materials and it is possible to obtain strong liquors from it, but the nontannin content is low. There are 3 parts tanning matters to 1 part nontannins. Hence the barkometer reading (measurement of sp. gr.) is apt to be misleading. The tannin of mimosa bark is astringent. Of the non-tannins present there is only a small proportion of sugary matters, or acid-forming substances. Myrobalans give a mellow tannage and are rich in glucosides, producing abundant acidity under suitable conditions. The use of myrobalans along with mimosa bark will counteract the astringency of the latter and make up for the deficiency in acidity. On account of the astringency of mimosa bark it is advisable not to use it in the early stages, but rather later, when the grain has become set and therefore is no longer liable to become drawn, and when the pelt is partially struck through. The leather produced by mimosa bark alone would have harshness and short fiber. Hence it should be used with mellow materials and not in the earlier stages of tanning. If the extn. is carried to the extreme limit, a red coloring matter is extd. However, the bark can be expended to contain only 3 to 4% tannin without the removal of too much coloring matter. If used with valonia or myrobalans, the slight pinkness helps to brighten the color produced by these materials. Since the tannin is a catechol, the leather darkens on exposure to light. Mimosa bark has been used much in Germany for the manuf. of heavy leather, and is very suitable for the purpose when used in conjunction with materials such as valonia. Mimosa bark tanned leather is particularly suitable for currying. The fibers are well sepd., so large quantities of grease can be incorporated. J. S. R.

Concrete shoes. ANON. *Concrete-Cement Age* 7, 110(1915).—Cement is used for weighting, waterproofing and strengthening sole leather. Ordinary sole leather is soaked in water until pliant, allowed to become half dry and given a coat of boiled linseed oil on the grain side. A bath is prepared of cement 8 oz., borax 2 oz., and cold H₂O to consistency of milk. To each lb. of leather is allowed 1½ lb. of the above mixt. The soaking lasts until satn. is reached (24 hrs.). The leather is then dried and oiled with linseed oil. The durability is increased 100 to 200%. A. A. KLEIN.

Analysis of nitrogen in leather waste (ROSE) 15.

Composite leather belts for minimizing slippage and stretch. C. E. CARPENTER. U. S., 1,160,040-1, Nov. 9. Layers of mineral-tanned and vegetable-tanned leathers are cemented to each other with the flesh sides in contact, by a cement formed of celluloid and acetone.

Synthetic tanning agents. BADISCHE. Brit., 17,172, July 20, 1914. Sol. condensation products are obtained by heating sulfonic acids of aromatic hydrocarbons, free from OH groups, in the presence or not of a condensing agent and under ordinary or reduced pressure; sulfonic acids of naphthalene, anthracene, etc., are suitable parent materials. According to examples, naphthalene-2-sulfonic acid is heated alone or with P₂O₅. The products ppt. glue and other colloids from soln. and can be used as tanning agents.

Tanning agents—azo dyes. BADISCHE. Brit., 3,382, Feb. 9, 1914. The tanning agents are obtained by treating, under pressure and at a temp. above 100°, hydroxy

compds. of the benzene or naphthalene series, or salts thereof, with HCHO, or a compd. yielding HCHO, and a neutral or acid sulfite; the reaction mass is preferably kept alk. throughout the process. According to examples, products are obtained from the following parent materials: phenol, HCHO, and Na_2SO_3 ; Na phenolate and Na HCHO-bisulfite; *m*-hydroxybenzoic acid, HCHO, and NaHSO_3 ; cresolmonosulfonic acid, HCHO, and NaHSO_3 . Such of the acids described above as contain a free *o*- or *p*-position to the OH group combine with diazo compds. to form azo dyes.

Condensation products from formaldehyde and naphthol- or naphthylamine-sulfonic acids. DEUTSCH-KOLONIALE GERB- UND FARBSTOFF GES. Brit., 8,818, Apr. 7, 1914. HCHO is condensed with 1- or 2-naphtholsulfonic acids or heteronuclear 1- or 2-naphthylaminesulfonic acids in neutral or slightly acid aq. soln. The process can be effected by using 1 mol. of HCHO to 2 mols. of sulfonic acid, or using 1 mol. of HCHO to 1 mol. of sulfonic acid; in the first case the reaction is effected at ordinary temp., in the second case heat may be applied. Products are specified from 2,6-, 2,7-, 1,4-, and 1,5-naphtholsulfonic acids, 1,5-, 1,6-, 1,7-, 1,8-, 2,5-, 2,6-, 2,7-, and 2,8-naphthylaminesulfonic acids. In place of HCHO, substances yielding it, such as trioxymethylene or methylal, may be used. The products ppt. glue from its solns. and combine with diazo compds. to yield azo dyes. They can be employed in tanning; a tanning liquor may be made by dissolving the condensation product in H_2O and adding alkali nearly to neutralize the soln., or the reaction mixt. can be dild. and used directly.

Tanning extracts. H. FRANK. Brit., 17,273, July 21, 1914. The difficultly sol. substances in crude quebracho liquors are rendered sol. in the cold by treating the hot liquor with an oxide, hydroxide, or salt of an alk.-earth metal, with the optional exclusion of air under pressure, the liquor being subsequently neutralized with acid. The acid may be such as to form with the alk.-earth metal a salt which is insol. or sol. with difficulty, so that the resulting tannic liquor contains very little salt in soln. As an example of carrying out the process, caustic lime is stirred into the hot liquor in the proportion of 10-15 g. to the liter, and the mixt. is heated for a long time in an autoclave at about 130° with the exclusion of air. HOAc, HCl, or other acid is then added to neutralize the lime, or where it is desired to obtain a liquor poor in salts, an acid is employed which forms a ppt. with the alk.-earth, this being removed by hot filtering. The insol. substances may be sepd. by cooling and clarifying, and the tannin content may be rendered sol. by further treatment as above described. The substances that resist the treatment may be dissolved by the known sulfiting process, giving a material having tanning properties inferior to those of the main portion which has been rendered sol. in the cold.

Gelatin sheets. R. A. MCQUARRY. Brit., 15,465, June 27, 1914. Sheets, which may be transparent, colored, or opaque, are made by distributing gelatin soln., to which a suitable antiseptic has been added, upon a glazed, enamelled, japanned, or varnished strip of flexible material, which is then beat round a curved surface such as a drying-wheel, and the gelatin, after drying, is stripped off and cut up or wound upon a reel.

Compositions of glue materials. W. PLINATUS. Brit., 12,143, May 24, 1913. Compns. of materials such as gelatin, glue, agar-agar, albumin and casein, and filling materials are mixed in a vacuum. Hardening substances such as aldehydes, chrome compds., or tanning substances may be added; or the hardening may be effected by gaseous or liquid HCHO, or by heating with steam and subsequently pressing.

Elastic or plastic masses from glycerol-gelatin. J. STOCKHAUSEN. Ger., 284,708, June 2, 1911. Addition to 277,653 (C. A. 9, 1136). Cf. C. A. 9, 2163.

30. RUBBER AND ALLIED SUBSTANCES.

R. T. STOKES.

Tetrachloroethane and its toxic properties. G. NOYER. *Caoutchouc et gutta-percha* 12, 8686(1915).—A general discussion. E. J. KELLEY.

Polymerization of isoprene under the influence of an aluminium-mercury couple (BÖRSCHEN) 10.

Isoprene. A. HEINEMANN. U. S., 1,159,380, Nov. 9. Vapors of turpentine oil are passed over Ag heated to about 450°, giving a yield of isoprene equal to 25% of the turpentine oil used, together with about an equal amt. of other depolymerization products. About 2000 cc. of vapor per hr. may be passed through a Ag tube of 6 mm. diam., 4 m. long, wound closely into a coil.

Synthetic caoutchouc. D. SPENCE and A. P. CLARK. U. S., 1,161,904, Nov. 30. Pinacol is heated with Ac_2O or KHSO_4 at 150° for 60 days to convert it partially into a caoutchouc-like product without intermediate isolation of the hydrocarbons formed, which may be polymerized in the latter stage of the process. The yield of caoutchouc is not stated.

Vulcanizing rubber articles. R. B. PRICE. U. S., 1,161,967, Nov. 30. A form around which the articles are molded is alternately dipped in a soln. of rubber and exposed to less than atm. pressure after each dipping to evap. the solvent in a closed chamber. Cf. C. A. 9, 2823.

Vulcanizing rubber. R. B. PRICE. U. S., 1,161,965, Nov. 30. The articles are heated to a low temp. before vulcanization and subjected to reduced pressure to withdraw all entrapped volatilizable materials from the rubber, which is then heated and vulcanized in the usual manner.

Apparatus for vulcanizing hollow rubber articles on forms. E. W. RUTHERFORD. U. S., 1,161,892, Nov. 30.

Apparatus for vulcanizing rubber tires. C. A. WILLEY. U. S., 1,162,535, Nov. 30.

Vulcanizing rubber tires, etc. R. B. PRICE. U. S., 1,161,966, Nov. 30. The tire is built up to substantially its final form while unconfined and then vulcanized by heating with glycerol or other liquid (in direct contact with the unconfined article) to the vulcanizing temp.

Apparatus for vulcanizing rubber tires. R. B. PRICE. U. S., 1,162,397, Nov. 30. Elec. heating is utilized.

Preparing rubber for vulcanization. R. B. PRICE. U. S., 1,158,843, Nov. 2. The rubber is compacted with rolls *in vacuo* after adding the vulcanizing agent.

Purifying sulfur monochloride. P. I. MURRILL. U. S., 1,159,327, Nov. 2. S_2Cl_4 which has been partially decompd. by contact with moist air is freed from impurities such as HCl and H_2O by allowing it to stand in contact with metallic Na or other alkali or alkaline earth metal, preferably for 20 hrs.

Obtaining rubber from rubber-bearing plants. D. VECCHINI. U. S., 1,159,137, Nov. 2. Rubber-bearing shrubs or barks are triturated at such speed and with material of regulated fineness such that the rubber is heated to an agglomerating temp. The material is then sepd. by screening.

Drying rubber. G. B. BRADSHAW. U. S., 1,161,603, Nov. 23. Wet rubber is heated throughout to about 100° and then subjected to a vacuum to effect evapn. of the contained moisture and produce a porous spongy mass.

Rubber substitute. G. NÜTH. U. S., 1,159,257, Nov. 2. A "factice" prepd. from S_2Cl_2 and a fatty oil is hardened and vulcanized by heating to 120-135° after mixt. with S and an aromatic amino compd., *e. g.*, aniline, α -naphthylamine, *m*-aminobenzoic acid, toluylenediamine, *o*-, *p*-, or *m*-toluidine, *m*- or *p*-xylydine.

Rubber substitute. G. NÜTH. U. S., 1,159,258, Nov. 2. A "factice" prepd. from a fatty oil and S_2Cl_2 is heated to 120-155° for 5-30 hrs. with NH_4OH , urea, $(NH_4)_2CO_3$ or aromatic amines to harden it and then vulcanized with S.

Synthetic caoutchouc substances. A. HEINEMANN. Brit., 17,253, July 21, 1914. The polymerization of butadiene, isoprene, dimethylbutadiene, and other hydrocarbons having conjugated double bonds, is effected by dissolving them in acetone or a homolog thereof and passing SO_2 into the soln., the product being purified from oily impurities by subjecting it to high pressure in a mold; it may be vulcanized or mixed with metal oxides or other fillers.

Coagulating India rubber. C. DE C. PINTO. Brit., 16,840, July 15, 1914. A coagulating prepn. consists of a soln. in alc. of preferably 2 kg. of creosote, 1 kg. of quinine-HCl, and 1 g. of Na_2CO_3 , which is dild. with H_2O or the whey or rubber milk. 10 g. of the soln. with 200 g. of whey may be used for coagulating 2 kg. of latex.

India rubber articles. R. B. PRICE. Brit., 17,193, July 20, 1914. As a modification of 10,695, 1913 (*C. A.* 8, 3507) treating articles formed of rubber or the like combined with fibrous materials or textiles, so as to withdraw air, gases, moisture, or other fluids from the article during or preceding vulcanization and after it has been formed substantially to its final shape. The article is subjected to a compacting pressure from the outside while the interior of the substance of the article is subjected to a lesser pressure. The exterior pressure may be produced by a rigid mold, by a flexible yielding element such as a diaphragm or flexible receptacles containing fluids or comminuted materials, or by fluids such as air, vapor of alc., NH_3 , etc., and the article may also be supported on the outside of a support or mold. The process may be applied to tires, hose, boots, shoes, etc.

Impregnating fabrics with rubber solution. G. W. BELDAM and A. M. B. RYALL. Brit., 19,097, July 18, 1914. Fabrics are impregnated with rubber soln. by passing the fabric, submerged in the liquid, over perforated surfaces, through which the liquid is forced on to and into the fabric, which, during the treatment is, caused to vibrate or "dither" by the action of the liquor or by mechanical means.

Published by the American Chemical Society, Easton, Pa.

Entered as Second-class Matter at the Post-Office, Easton, Pa.

Communications for the Editor should be addressed to E. J. Crane, Ohio State University, Columbus, Ohio.

The Council have voted that no claims for copies lost in the mails can be allowed, unless such claim is received within "sixty days" of the date of issue, nor if due to failure to give sufficient notice of change of address. Charles L. Parsons, Secretary.

Remittances for annual membership dues or for subscriptions, changes of address, orders for subscriptions or back numbers, claims for missing numbers and all matters intended for the Proceedings should be sent to the Secretary, Charles L. Parsons, Box 265, Washington, D. C.

Secretary's Office: Box 505, Washington, D. C.

Eschenbach Printing Company, Easton, Pa.

The American Chemical Society

The Board of Directors of the American Chemical Society has fixed the following schedule of prices for its publications

Subscription Rates

Journal American Chemical Society.....	\$ 6.00
Chemical Abstracts.....	6.00
Jour. Industrial and Engineering Chemistry.....	6.00
Two Journals to same address.....	10.20
All three Journals to same address.....	12.60

Back Numbers and Volumes

	To Members	To Non-members
Single Numbers: J. A. C. S.; J. I. E. Chem. or Chem. Abs....	0.50	0.60
Proceedings, Vol. 1 (1876); Vol. 2 (1877).....	2.00	2.50
J. Am. Chem. Soc., Vols. 1-16 inclusive, each....	4.00	5.00
J. Am. Chem. Soc., Vols. 17-37 inclusive, each....	5.00	6.00
Chem. Abs., Vol. 1, 2, 3 or 5 complete, each.....	10.00	12.00
Chem. Abs., Vol. 4, 6, 7, 8 or 9 complete, each....	5.00	6.00
Index to Vols. 1-20, J. Am. Chem. Soc.....	0.50	0.75
Index to Chem. Abstracts, Vol. 1, 2, 3, 4, 5, 6 or 7.....	1.00	1.00
Jour. Ind. and Eng. Chem., Vols. 1-7.....	5.00	6.00
Foreign Postage, each Journal 75c.; Chemical Abstracts, \$1.00 a year.		

Special Discounts to Newsdealers, Libraries and Institutions of Learning

Complete sets, Vols. 1 to 35, of the Journal; Proceedings, Vols. 1 and 2, and Vols. 1 to 7 of Chemical Abstracts may be had of the Secretary.

The following numbers can be furnished only in complete sets, viz: J. Am. Chem. Soc., 17 (1895), 1 and 8; 18, 5; 19, 1; 20, 3; 22, 3.

Besides the above, the following numbers can be furnished only in complete volumes, viz: J. Am. Chem. Soc., 26, 4; 29 (1907), 4; 30 (1908), 2, 3, 4, 5, 6 and 7; 33, 3, 4 and 9; 34, 9, 10 and 11; Chemical Abstracts, 1 (1907), 3, 12, 13, 14, 15 and 16; 2 (1908), 1 and 2; 5, no numbers except 1, 4 and 6; Jour Ind. and Eng. Chem., 1, only No. 11; 3, Nos. 3 and 12; 4, Nos. 3, 4, 5, 7 and 10; 5, No. 1.

Advance payment is required and should be made by check or money order only. Stamps not wanted.

The Council has voted that the Secretary shall honor claims for non-receipt of publications only if made within sixty days of their issue. Claimants must also directly state that the publication was not delivered at their recorded address. "Missing from files" is no proof of non-receipt.

The Society will not be responsible for loss due to change of address unless notification is received one week in advance of issue.

Members or subscribers desiring their Journals or Abstracts forwarded from an old address should always notify their Postmaster and leave necessary postage.

The names of members and subscribers, whose Journals or Chemical Abstracts cannot be delivered by the Post-Office Department, will be cut off the mailing list at once, and will not be restored until correct addresses have been furnished.

In the absence of other information, the notices of change of address received from the Post-Office Department will be considered as correct, and the mailing list changed accordingly.

All communications should be addressed to

CHARLES L. PARSONS, Secretary,

Box 505, Washington, D. C.

PATENTS

Abstracts of patents are included under the appropriate divisions of the journal: those on organic compounds, unless they pertain especially to some other division, are under Pharmaceutical Chemistry. The abstracts of U. S. patents are prepared by Earl T. Ragan, those of Canadian patents by Russell S. Smart, of Fetherstonhaugh & Smart, Ottawa (50 Queen St.), and all others by O. D. Swett. Most German patents are prepared, with permission, from the abstracts in *Chemiker-Zeitung* and Italian patents from those in *Annali di chimica applicata*. All other patents are obtained direct from the specifications.

Copies of any patent may be obtained for: United States, 5 cents, sent to the Patent Office, Washington, D. C.; French, one franc, sent to L'Imprimerie Nationale, 87 rue de Vieille du Temple, Paris; German, one mark, sent to the Patent Office, Berlin; British, eight pence, sent to Patent Office, London (extra postage outside United Kingdom); Austrian, write to the Patent Office, Vienna; Danish, write to the Patent Office, Copenhagen; Norwegian, 1 crown, Patent Office, Christiania; Swedish, 1 crown, Patent Office, Stockholm. Of Canadian patents, manuscript copies only are obtainable. They may be secured from Fetherstonhaugh & Smart, or the Commissioner of Patents direct. Estimates of cost may be obtained in advance.

In ordering a copy of a patent, the number of the patent, name of the patentee, and subject of the invention should be stated.

CHEMICAL ABSTRACTS

Vol. 10.

FEBRUARY 10, 1916.

No. 3

I. APPARATUS.

L. C. JONES.

The evolution of evaporating apparatus. HUGO SCHRÖDER. *Grimma. Chem. App.* 2, 89-91, 101-4, 116-8, 128-31, 139-41, 187-9, 199-202, 209-13(1915).—A review, with 40 cuts and mathematical data, of the development of app. "for boiling liquids in order to remove more or less—to any desired degree, or as much as possible—of the solvent (usually H_2O); to evap. them and recover the distd. substances in concd. form, or to use the evolved steam in a series of suitable app. as a medium of energy (heat carrier)."

J. H. MOORE.

Absolute viscosimeter. ANON. *Engineering* 100, 554(1915).—The time required for an observation is the chief objection to the usual type of instrument, the principle of which is the flow of fluid through a capillary tube. This is overcome in the viscosimeter here described by increasing the pressure which causes the flow. An additional improvement is a device by means of which the pressure is maintained const., resulting in a simplification of calcns. The app. consists essentially of 3 parts: the viscosimeter buret, the const. pressure app., and the pressure gage. The viscosimeter buret consists of 2 cylindrical glass vessels, one storage and the other measuring, connected by a U-tube, one leg of which is large bore and the other capillary, all water-jacketed. The capillary has ground glass ends of standard size and taper so that it is replaceable. The measuring vessel has 2 Pt wires sealed into its side. The vol. of the vessel between the Pt points is detd. by weighing with Hg. The storage vessel is connected to the pressure app. and gage by a 3-way tube and cock. The pressure app. consists of 2 vessels of Hg, adjustable at different levels. The upper Hg vessel is supported by a spring adjusted so that the vessel is raised as the Hg flows out, thus maintaining a const. head. The pressure is transmitted by air. The pressure gage is an ordinary Hg manometer. In use the time required for the fluid to fill the buret, between the 2 Pt points, and the pressure are measured. Formulas and tables are given. The app. was invented by W. Stone, chief elec. engr. Victorian Railways, Australia, and has been successfully used in testing lubricating oils.

F. A. HARVEY.

A hydrogen electrode vessel. WM. MANSFIELD CLARK. U. S. Dept. Agric. *J. Biol. Chem.* 23, 475-86(1915).—Description of an app. that can be mechanically shaken, so as to ensure prompt satn. of the system with H. Details are given.

I. GREENWALD.

Some improved electrical laboratory apparatus. C. M. JOHNSON. *J. Ind. Eng. Chem.* 7, 960-1(1915); cf. *C. A.* 2, 1800.—Descriptions of: (I) A quick heating elec. furnace for the detn. of C in steel, etc., with train. The train is a simplification of the type previously described, while the furnace is of a new split muffle type with replaceable heating elements of nichrome wire imbedded in alundum cement. (II) A new type of portable lab. rheostat. The resistance elements of nichrome wire are mounted upon a framework of asbestos board. (III) A new rectangular lab. elec. muffle furnace with solid heat insulation case. The heating element is similar to that of the combustion furnace. A white solid case of kieselguhr surrounds the working muffle and heating element. The furnace is supported and enclosed by a stout soft-steel frame.

F. A. STRAUSS.

[Automatic regulator.] Tungsten-lamp shunt valuable for preventing arcing at contacts. ANON. *Elec. World* 66, 1435(1915).—To do away with excessive pitting of the contacts of an automatic feeder regulator due to the large current taken by the secondary relays, two 15-watt W lamps were shunted across the contact points. These lamps were selected on account of their desirable temp. coeff. The current passing through the lighted lamp is not sufficient to hold the relay. C. G. F.

The use of water meters in steam boiler practice. H. WINKELMANN. *Chem. App.* 2, 213-5(1915).—Brief descriptions of the Steinmüller, Kenedy, and Siemens-Halske meters, the first and last guaranteed accurate to 0.1% and 1.0%, resp., and of the Cref equalizer, for regulating the feed to each boiler in a battery. J. H. MOORE.

Development of nephelometers (KOBBER) 7.

Acetylene generator. A. MESSER. U. S., 1,163,939, Dec. 14.

Apparatus for automatically testing urine or other liquids. B. SAGI and E. SAGI. U. S., 1,163,693, Dec. 14.

Filters. E. A. ANDREWS and A. E. OWEN. *Brit.*, 18,096, July 31, 1914. A filter of the kind in which a layer of filtering medium is cleansed by a back-wash of liquid is fitted with means for revolving the whole body of the filtering medium over a number of stationary jets of liquid.

Oil presses. C. BENSON. *Brit.*, 18,270, Aug. 7, 1914.

Testing gases. W. GAUDIE and G. WILKINSON. *Brit.*, 18,280, Aug. 7, 1914. Gas-testing app. of the diffusion type is provided with a system of levers for amplifying and transmitting the movements of the diaphragm to elec. contacts controlling the alarm or signal.

De-pericarping fruit. H. W. GABBETT-FAIRFAX. *Brit.*, 18,050, July 30, 1914. Constructional details of a machine for removing the pericarp from oil-bearing and other fruits, comprizing a rotary table carrying curved blades to which the fruit is guided from a hopper by oppositely curved blades carried by a casing. The casing may rotate oppositely to the table. The table may be either flat or conical and may be turned up at the periphery, or the casing may be turned downwards to surround the table. The pericarp is thrown by centrifugal action against a screen through which oil passes, the residue falling into a chamber arranged in a steam-chamber. The kernels are discharged through apertures in the surrounding frame.

Gas producers, blast furnaces. T. BAIRDOW. *Brit.*, 18,381, Aug. 7, 1914. To prevent the passing of flames and hot gases from the poking-holes of gas-producers, blast furnaces, etc., steam, air, H₂O, or other fluid is injected into the poking-hole from a number of horizontal slits in a pipe surrounding the hole.

Steam chambers for superheaters. F. WERLE. *Ger.*, 285,142, Mar. 3, 1914.

2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS.

Assistants: E. B. MILLARD and A. B. CARTER.

Introduction to the theory of relativity. F. H. LORING. *Chem. News* 112, 226-7, 236-7, 248-50, 260-2(1915).—The work of the various investigators in this field has been brought together and simplified for beginners. E. B. MILLARD.

An elementary account of the quantum theory. J. RICE. *Trans. Faraday Soc.* 11, 1-18(1915). E. J. C.

Recent researches in the Wolcott Gibbs Memorial Laboratory of Harvard University. T. W. RICHARDS. *Science* 42, 845-51(1915).—An address. E. J. C.

History of the development of hydrometry. HERMANN SCHELENZ. Cassel. *Chem. Ztg.* 39, 913-5(1915).—A brief bibliography is appended. Cf. *Chem. Ztg.* 27, 88(1903); C. A. 6, 1693. J. H. MOORE.

The calibration of thermometer tubes and the function equation. GIULIO AND RSOLI. *Atti reale ist. Veneto, sci. lettere ed arti* 74, 319-25(1915).—A mathematical paper. E. J. WITZEMANN.

Role of pressure in chemical phenomena. E. BRINER. *Rev. gén. sci.* 26, 551-7(1915); cf. C. A. 7, 2360, 2523, 3888; 8, 1530; 9, 880, 2479.—Discussion and review of the previous papers. E. B. MILLARD.

Theory of the rise and fall of particles with Brownian movement. ERWIN SCHRÖDINGER. *Physik. Z.* 16, 289-95(1915).—Mathematical. E. B. MILLARD.

Mobility of the positive and negative ion at different temperatures and at constant gas density. H. A. ERIKSON. *Phys. Rev.* 6, 345-53(1915).—Mobilities have been detd. between the temps. -184 and $+63^{\circ}$ at const. gas d. in dry and moist air which had been ionized by a polonium tube, by means of an alternating field method similar to Rutherford's. The mobility of the positive ion is a max. at about 0° ; that of the negative ion also shows a max., but is more erratic in behavior. No definite conclusion has been reached, but it seems that the variation of the positive mobility is not due to clustering. Variations in the negative mobility seem to be due to clustering combined with an effect similar to that causing the variation of positive mobility. E. B. MILLARD.

Electron optics of the hydrogen molecule. II. A. HEYDWEILLER. *Verh. deut. physik. Ges.* 17, 359-62(1915); cf. C. A. 9, 2347.—The H_2 mol. consists of a H cation and a H anion with 1 loosely bound valence electron and a certain number of bound and rapidly vibrating electrons of nearly equal frequency. The number of these latter electrons is not definitely known, but is almost surely greater than 1, from considerations of the electron-optics of the H-cation in H_2O . The ion refraction of the H-cation is nearly equal to the difference between its equiv. refraction and that of the Mg^{++} ion. Both Mg^{++} and Al^{+++} have smaller equiv. refractions than the H ion. If there is only 1 electron in the neutral H_2 mol., there could be no electron in the H^+ ion, and it should have the smallest equiv. refraction of any ion. Two pairs of salts of H and Al with common anions, and 4 pairs for Mg and H, have been used to det. the equiv. refraction, and in every case the values for H were larger than those for the salts. E. B. MILLARD.

Conduction of electricity through metals. J. J. THOMSON. *Electrician* 76, 13-5(1915).—The exptl. work of Onnes with superconductors is briefly reviewed. The effects discovered by O. are in accordance with the theory of metallic conduction in the "Corpuscular Theory of Matter" (p. 86). The atoms of some substances, including the metals, contain electrical doublets—i. e., pairs of equal and opposite elec. charges at a small distance apart. In the normal state of a substance the axes of these doublets are distributed in all directions; when an elec. force acts on the substance, the axes tend to point in the direction of the force, and the moments of the doublets have a finite resultant in this direction. If the atoms were perfectly free to move, the smallest force would be able to direct all of the axes in the same direction, but influences are at work which prevent this. In gases, there are collisions which tend to knock the axes out of line as fast as they are brought into line by the elec. force. In the case of solids and liquids, though there may not be collisions between the mols., the rotation of the mols. endows them with a quasi-rigidity, making each mol. behave as if its axis were

acted upon by a restoring couple proportional to the angle through which the axis has been displaced. The value of the resultant of the moments will be a function of the ratio of the deflecting couple acting on the doublet to the restoring couple brought into play when the axis is deflected through unit angle. The nature of the function is discussed in a math. form not suitable for brief review. From the point of view of this paper the part played by the electric force in metallic conduction is to polarize the metal, *i. e.*, to form chains. When once they are formed, the electricity is transmitted along them by the forces exerted by the atoms on the electrons in their neighborhood. If the polarization remains after the elec. force is removed, the current will remain, as it did in Onnes' expt. with the Pb ring. Equations are given for the temp. at which the metal passes into the superconducting state. The persistence of the chains after the elec. force is removed is due to the disturbances of thermal agitation being too weak to break up the chains once they are formed. The chains are held together by the forces of the elec. doublets in the chain itself as well as by the external elec. forces. If the sp. heat of a metal becomes zero at abs. zero the metal will always become a superconductor unless there are directive forces (similar to those of crystals) which pull the doublets out of line in the chains.

E. B. MILLARD.

Transference of electricity by colloidal particles. FRANK POWIS. *Trans. Faraday Soc.* 1915 (advance copy).—The method of calcn. assumes that the increase in cond. of H_2O when electrodes of a noble metal are sparked under H_2O is due entirely to the cond. of the colloid formed (positive or negative) and to the ion balancing it. From existing data the charge on a coarse Ag sol was calcd. as 2385×10^{-10} electrostatic units per particle, or 795 times the charge on a univalent ion. Other calcns. are given, in which the order of magnitude of the charge has about this value. P. thinks that the colloids do not adsorb ions in the way usually assumed, but in such a way that the concn. of cations and anions gradually decreases with increasing distance from the particle until it finally becomes equal to that in the bulk of the surrounding medium. The ions near the particle will be bound to it with such force that the particle cannot move without taking the ions with it, and the ions far from the particle will be only weakly held; the resultant of the charges determines the direction of motion of the colloid. A larger proportion of the divalent ions adsorbed would probably be close to the particle, thus accounting for the predominating influence of ions of higher valency. On this view the charge cannot be calcd. from Stokes' law, or from the increase of cond., since there is no charge in the usual sense of the term, and it would only be possible to calc. the minimum number of ions which would be required to give the extra conductivity.

E. B. MILLARD.

Molecular attraction. XII. J. E. MILLS. *J. Phys. Chem.* 19, 650-9(1915); cf. *C. A.* 9, 1561.—The relation $dP/P = dT/T$ is either exactly or approx. true for a large number of cases. P is the total pressure, *i. e.*, the numerical sum of the external and internal pressures. There follows a discussion of thermodynamic formulas in general. M. is unable to understand how such a relationship as the Clausius-Clapeyron equation can be applied to fusion, vaporization and other phase change phenomena. Several of the relations previously derived in this series of papers are discussed. The amt. of energy retained by a system of n particles forming a stable system under the action of mol. attractive force is equal to the amt. of energy given out by these n particles in coming into the system from an infinite distance apart. Temp. affects this relation in a manner not yet understood.

E. B. MILLARD.

Baly's theory of chemical reaction and reactivity. WM. H. DEHN. *J. Am. Chem. Soc.* 38, 1-15(1916); cf. *C. A.* 9, 1411.—Polemical. The theory is said to be based entirely on light absorption phenomena, the nature of which is unknown. "Baly's exptl. methods have often been modified during the past decade, but give little confi-

dence of value for the establishment of his theory. As 'proofs' of his theory the expts. are too limited and almost entirely unconvincing. Drawing definite structural or dynamic conclusions from absorption phenomena is unwise; grounding a comprehensive chemical theory on the same is too speculative to serve any useful purpose."

E. B. MILLARD.

Baly's theory of chemical reaction and reactivity. Reply to Dr. Dehn. E. C. C. BALY. *J. Am. Chem. Soc.* 38, 15-20(1916); cf. preceding abstr.—In reply, B. has "tried to show that he (D.) does not quite understand and that the gift of sympathy is not his."

E. B. MILLARD.

Relation between boiling point and constitution. L. CASALE. *Atti accad. sci. Torino* 50, 809-23(1915).—In 1842, Kopp stated that equal differences in chem. compn. of org. compds. produce equal differences in the b. p. This statement was variously modified and Walker (*J. Chem. Soc.* 65, 193(1894)) proposed his formula $T = aM^b$ in which T = abs. temp. and M the mol. wt. and a and b are arbitrary const. E. Boggio-Lera (*Gazz. chim. ital.* 39, I, 441) proposed $T = K\sqrt{M+C}$, in which K and C are const. chosen for each series of compds. Ramage (*Camb. Philos. Soc. Proc.* 12, 445(1904)) modified W.'s formula by introducing n , the number of C atoms; thus $T = a\sqrt{M(1-2^{-n})}$, which gives good values for the lower members of a series. B.-L.'s formula was later modified by Sugden (*C. A.* 9, 10) thus: $T = a\sqrt{M} + (b/\sqrt{M}) + (a/bM)$. The 4 above formulas give defective results because they only consider the b. p. as a function of mol. wt. Young (*J. chim. phys.* 3, 250(1905)) proposed the formula $\Delta = 144.86/T^{0.0148}\sqrt{T}$, which gave good results for the paraffin series, but failed for the other series. C. proposes $\Delta = 109.2/n^a$, where Δ is the difference in the b. p. of 2 adjacent terms arising from the substitution of H with CH_3 as a function of the abs. b. p. of CH_4 and of n the number of C atoms. a is an arbitrary const. The series CH_4 , C_2H_6 , $\text{CH}_3(\text{Me})_2$, $\text{CH}(\text{Me})_3$, $\text{C}(\text{Me})_4$, is a continuous series in which an H is successively substituted in CH_4 with Me. In the series MeCH_2Me , $\text{Me}(\text{CH}_2)_2\text{Me}$, $\text{Me}(\text{CH}_2)_3\text{Me}$ each term differs from the preceding by a $-\text{CH}_2-$ group and propane which is one of the 1st series is the 1st member of this series. It is permissible to suppose that the increase in the b. p. in a higher homolog is in some way proportional to the force with which the added group is attached. And this force would be nearly const. for the 2nd series but would vary in a continuous way for the 1st series beginning with C_2H_6 . In this series the substituting Me is bound successively to a CH_3- , a $-\text{CH}_2-$, a $-\text{CH}-$ and a $-\text{C}-$ group. In the above formula a is proportional to this force and the values are 0.61, 0.675, 0.74 and 0.805, resp. The value $a = 0.675$ for CH_3Me in the 1st series holds for all members in the 2nd. and so the b. p. of any term in the $\text{C}_n\text{H}_{2n+2}$ series is given by the formula $\Sigma 109.2/n^{0.675}$. The b. p. of CMe, will be obtained from $\Sigma 109.2/n^{0.805}$, where $n = 5$. If the hydrocarbon partakes of 2 series, as $\text{MeCH}_2\text{CH}_2\text{CH}(\text{Me})_2$, the b. p. is calcd. from that of the fundamental hydrocarbon, namely butane in which 2 Me's are substituted: thus $109.2/1^{0.675} + 109.2/2^{0.675} + 109.2/3^{0.675} + 109.2/4^{0.675} + 109.2/6^{0.74} + 109.2/8^{0.74}$, in which the sum of the 1st 4 is the b. p. of butane and the last 2 represent the increase due to 2 Me groups bound to $-\text{C}-$. C. calcd. the b. ps. for the paraffin series up to $\text{C}_{15}\text{H}_{32}$ and found an average difference of 0.55° between the calcd. and observed values. In the last term the difference was $+3.7^\circ$. C. calcs. the b. p. of $\text{C}_{15}\text{H}_{32}$ for 760 mm. pressure from the value for 15 mm. and finds that the value agrees closely with the value calcd. from this formula; he considers that this throws doubt on the correctness of the observed value. In another table the calcd. and observed b. ps. of 22 branched-chain aliphatic hydrocarbons are given. The av. difference between the observed and calcd. value is 0.75° . This formula which takes into consideration the constitutive properties of compds. was next applied to the ethylene hydrocarbons. When a H atom in

$\text{CH}_2\text{:CH}_2$ is substituted with Me it is attracted by the $-\text{CH}=\text{}$ group with a greater force than in the absence of the double bond. The value for a in this case is 0.615. If a 2nd H atom is substituted by Me then a will be 0.675 just as in the case of the satd. hydrocarbons. Thus the b. p. of propylene, MeCH:CH_2 , will be the b. p. of $\text{CH}_2\text{:CH}_2$ or $(170.5 + 109.2/3)^{0.615}$. For $\text{Me}_2\text{C:CH}_2$ the b. p. is $(170.5 + 109.2/3)^{0.675} + 109.2/4^{0.675}$. The calcd. values for 25 branched and straight chain members of the ethylene series are given and differ on the av. 1.6° from the observed values. C. assumed that the b. p. of CH_4 (109.2) is incorrect and that the mean (114°) of the values observed by Wroblewski, Olszewsky, Ladenburg and Krugel is correct. The values thus obtained for the straight and branched-chain paraffins differ very little except in the case of CH_4 and isobutane. The b. ps. of the normal paraffins at 15 mm. were also calcd. and compared with the values observed by Kraft. The av. difference is 1.18° . The b. p. of a hydrocarbon $\text{C}_n\text{H}_{2n+2}$ is the sum of the effect of the central groups (CH_2CH , C) which contributes the same value, while the terminal CH_3 groups contribute different amts. according as they are attached to 1 or to several C atoms. If in $\text{C}_n\text{H}_{2n+2}$ the number of central C groups is indicated by a , the number of isolated Me groups by b , the number of pairs of Me groups united with the same C atom by c , the number with 3 Me groups by d and the number with 4 by e then its abs. b. p. will be $T = 114/1^{0.7} + 114/2^{0.7} + \dots + 114/a^{0.7} + 114/(a+1)^{0.77} + 114/(a+2)^{0.77} \dots 114/(a+b)^{0.77} + 114/(a+b+1)^{0.8033} + 114/(a+b+2)^{0.8033} + \dots + 114/(a+b+c)^{0.8033} + 114/(a+b+c+1)^{0.8366} + \dots + 114/(n-e)^{0.8366} + 114/(n-e+1)^{0.87} + 114/(n-e+2)^{0.87} + \dots + 114/n^{0.87}$. The value of the arbitrary const. 0.77 increases by 0.0333 through the presence of 1 Me group; another raises it 0.0666 more; 2 others 0.0999. The general form for the type $\text{C}_n\text{H}_{2n+2}$ is $T = \sum_{i=1}^{(n-2)} 114/(n-i)^{0.7} + 114/(n-1)^{0.77} + 114/n^{0.77}$. Also in *Gazz. chim. ital.* 45, I, 567-79(1915).

E. J. WITZEMANN.

Oxidation and reduction without the use of acid. II. Reaction between stannous chloride and potassium dichromate. A contribution to colloidal chemistry. MARKS NEEDLE AND J. C. WIRT. *J. Am. Chem. Soc.* 38, 47-52(1915); cf. *C. A.* 9, 2826.—Samples of 0.4 g. SnCl_2 were dissolved in 50 cc. H_2O and rapidly titrated with $\text{K}_2\text{Cr}_2\text{O}_7$, in some cases after adding HCl and in others without acid. After adjusting the indicator, the stoichiometrical relations between the two substances were identical, whether acid were present or not. In its absence, the turbidity due to the hydrolysis of SnCl_2 was rapidly discharged by dichromate, and the end-solution had a distinct (faint) fruity odor. After titration, the solns. were evapd. to dryness and extd. with alc. The material sol. in alc. consisted of a mixt. of hydrous oxides of Sn and Cr, and hydrated CrCl_3 . Both extn. with CS_2 and dialysis of the product showed that SnCl_4 was not present. KCl was shown to be one of the products of the reaction. The hydrosol obtained by dialysis and evapn. contained practically half of the Cr, all of the Sn, and a negligible amt. of Cl.

E. B. MILLARD.

Dual theory of acid catalysis. Catalytic activity of monochloroacetic acid in the presence of its salts. H. M. DAWSON AND C. K. REIMAN. *J. Chem. Soc.* 107, 1426-37(1915); cf. *C. A.* 7, 334; 8, 1373, 2293.—Expts. on the cond. and viscosity of 16 solns. of CH_2ClCOOH and 9 of its Na salt at 25° are reported. The "Ostwald app." was used for viscosities. The rate of isomeric change of acetone in the presence of CH_2ClCOOH and varying amts. of its Na salt was determined as previously described, with 20 cc. of acetone, 0.005 mol I, and approx. 0.01 mol. KI. Further support was obtained for the view that acid catalysis involves 2 simultaneous changes in which the active agents are the H ion and the non-ionized acid. Results of the expts. with mixts. of acid and salt are in excellent agreement with reaction velocities calcd. from the equa-

tion $v = k_m\alpha + k_{m'}(1 - \alpha)$, where k_m and $k_{m'}$ are the activity coeffs. derived from expts. with varying amts. of CH_3ClCOOH in the absence of salt. With increasing quantities of the Na salt the velocity of the reaction approximates the lower limiting value which represents the effect of the un-ionized acid. The influence of added salt is quite different from that found by Arrhenius in his expts. on the inverting action of HCOOH and HOAc in the presence of the corresponding salts. E. B. MILLARD.

Activation of chlorate solutions by osmium. III. Separation of hydrogen and methane, catalysis of oxygen-hydrogen mixtures. K. A. HOFMANN AND O. SCHNEIDER. *Ber.* 48, 1585-93(1915); cf. *C. A.* 7, 3088.—Quantities of the salts of the Pt metals corresponding to about 1 g. of K_2OsO_4 were evapd. to dryness with HCOOH , and taken up with 15 g. NaClO_3 , 2 g. NaHCO_3 and 100 cc. H_2O . These mixts. were little active toward H, and in the decreasing order Pt, Rh, Ru, Pd, Au, Os, Ir, Ag, and somewhat less active toward CO, in the order Rh, Au, Pt, Ru, Pd, Ir, Ag. Mixts. contg. Os were often made more active by the addition of OsO_3 . Clay tubes were dipped in 5% PtCl_4 soln., ignited, and put into a Hempel pipet with solns. of 35 g. NaClO_3 , 5 g. NaHCO_3 , 0.05 g. PdCl_2 and 0.02 g. OsO_3 . With this app. it is possible to sep. H from CH_4 or N much more easily than with the usual burning over asbestos. The speed of oxidation of the H by NaClO_3 depends on the surface of platinized tubes exposed, and may be as great as 100 cc. per hour without shaking the pipet. After the pipet has been filled with H twice, a film (probably $\text{PdO}_2\text{-OsO}_3$) is formed which aids the Pt in oxidizing the H at the expense of the chlorate, after which the pipet will absorb large quantities of H for months. Gases contg. S, P vapor, PH_3 and NH_3 act as contact poisons, but are usually removed early in the course of a gas analysis. In the presence of much CH_4 or N the accuracy of the results is somewhat less than when pure H was used. Oxidation of H by gaseous O in the absence of chlorate took place with a max. speed at a concn. of H somewhat greater than $\text{H}_2 + \text{O}$, and the velocity of absorption fell off rapidly with increasing % of O in a manner indicating the possible formation of a less active Pt oxide. Better results were obtained with H-air mixts. CO could be detd. by oxidation with NaClO_3 in a soln. contg. H_3PO_4 in place of NaHCO_3 as above. After use in this detn., the pipet's power to oxidize H was unchanged, so that CO cannot act as a contact poison E. B. MILLARD.

Theory of solutions. Influence of change of volume on specific refraction in mixtures of liquids. JOHN HOLMES. *J. Chem. Soc.* 107, 1471-7(1915); cf. *C. A.* 8, 1371. —New values of $n_D^{16.5}$ for mixts. of MeOH and H_2O , and of $d_4^{16.5}$ have been detd., and the same quantities for $n\text{-C}_3\text{H}_7\text{OH}$ have been recalcd. The deviation from theoretical n follows closely the change in vol. on mixing. Change of vol. followed change in n also for the following mixts. in which an increase in vol. occurs: EtI and EtOAc , C_6H_6 and HOAc , acetone and CS_2 . The relative complexities of the liquids are the same as those deduced from the solubilities and d. detns. CH_3OH , $\text{C}_2\text{H}_5\text{OH}$ and $\text{HC}_2\text{H}_3\text{O}_2$ represent the true formulas of MeOH , alc., and acetic acid, but those for Et iodide, benzene, and CS_2 should be $(\text{C}_2\text{H}_5\text{I})_2$, $(\text{C}_6\text{H}_6)_2$, $(\text{CS}_2)_2$. These values support the miscibility theory of the first paper, one of the requirements of which was that the mol. complexity of a liquid shall be independent of the liquid with which it is mixed. The max. absorption of heat on mixing CS_2 and acetone occurs at CS_2 , 0.45 $\text{C}_2\text{H}_6\text{O}$, which is close to the concn. at which max. vol. and n were found for the same mixt. E. B. M.

Changes in volume upon solution in water of the halogen salts of the alkali metals. II. G. P. BAXTER AND C. C. WALLACE. *J. Am. Chem. Soc.* 38, 70-105(1916); cf. *C. A.* 5, 2455.—New data are presented for the halogen salts (except fluorides) of all 5 alkali metals, covering nearly all concns. from satn. down for temps. between 0° and either 50 , 70 , or 100° . A weighed amt. of salt was dissolved in nearly a minimum quantity of H_2O and the vol. of the soln. was adjusted to a mark in a 50 cc. flask at the

highest temp. employed. The flask was then cooled to room temp. and weighed; after this the adjusting of the vol. and weighing were carried out at several lower temps. Next the soln. was transferred quantitatively to a 100 cc. flask and the operations repeated at the same temps., beginning with the highest. Then 250, 500 and 1000 cc. flasks were used. From the vols. of the flasks, and the vols. of salt and H_2O employed, the change of vol. was calcd. for each salt at each temp. Great care was taken to have the salts pure and dry when weighed, and the usual vacuum corrections have been applied. Following the tables, which show wt. of salt and wt. of H_2O , wt. of soln., vol. of each, d. of soln., mol. concn. of salt, change in vol., change per g. and change per mol., are shown curves in which the change in vol. per gram of salt is plotted vertically against concn. in mols per l. horizontally. From these curves the d. of any soln. of any of the 15 salts at any temp. may be calcd. from the ratio: $(wt. soln.)/(vol. soln.) = (wt. H_2O + wt. salt)/(vol. H_2O + vol. salt = change in vol. during soln.)$. Tables are shown of the contraction on soln., and on formation from the elements, of the salts. The algebraic sum of these vol. changes is negative for all 15 salts. This quantity, which represents the contraction produced in the formation of the soln. from 1 g.-atom each of free metal and halogen and the H_2O , was previously shown to be additive for Li, Na and K salts up to molar concn. New values for all 15 salts at concns. up to 5 molar, at 25°, show that the additive relation holds for all of the salts, and for higher concns. The explanation of the vol. changes, previously advanced on the Richards hypothesis of compressible atoms, is further supported by the new data. The following changes are assumed to take place during soln. and dissociation: (a) when the mols. dissociate, they are freed in large part from the compression due to chem. affinity, with considerable expansion (from 15 to 56% of the original vols. of the uncombined elements). (b) when the ions (and probably the mols.) are combined with H_2O , both the hydrated substance and H_2O undergo compression. The latter effect varied regularly with the compressibilities of the substances involved, as well as with their affinities for each other. The effect of rising temp. is found in general to diminish contraction, owing to lessened hydration of all the substances concerned. Exceptions are LiCl and LiBr at ordinary temps., and KCl at higher temps. No simple method exists for sepg. the effects due to ionized and un-ionized material, because of the varying magnitude of the change for each ion or mol. with changing concn. E. B. M.

Reciprocal solubility of copper and lead. B. BOGITCH. *Compt. rend.* 161, 416-9 (1915).—Melts of Cu and Pb form 2 layers when the % Cu is over 34.5 and less than 87. If the temp. is above 940° the double layer disappears, and no difference is found between the top and bottom of the melt. E. B. MILLARD.

Heats of solution of substances in dilute and concentrated solutions. Heat of solution of sea salt. A. COLSON. *Compt. rend.* 161, 414-6 (1915).—Heats of soln. per mol. of NaCl were: in 2.4 l. H_2O —1500 cal. at 8°, —1100 at 22°; in 4.5 l. H_2O —1510 and —1546 cal., resp. From these data and heats of diln. of satd. solns. to these concns., the heats of soln. to satn. have been detd. In the neighborhood of 15° the mol. heat of satn. was —460 cal., and the variations with temp. were small. For NaCl there does not exist a region of const. heat of soln. independent of the concn. E. B. M.

Heats of saturation of some alkali salts. A. COLSON. *Compt. rend.* 161, 458-61 (1915).—Molar heats of satn. of aq. solns. have been detd. from heats of soln. in 4 to 8 l. per mol. and the heats of diln. of satd. soln. to this concn. for KNO_3 , KCl and NH_4Cl . The heats of mol. satn. for KNO_3 are —7145 cal. at 13.5° and —6950 cal. at 18.5°. For KCl these values were —4082 at 5.5°, —4001 at 12.5°, —3890 at 17.9°; for NH_4Cl —3851 at 14.9°, —3714 at 22.3°. The heats of satn. vary about 7% from the mean between 5 and 21°, and are in every case less than the heats of soln. in such amts. of solvent that the heat effect is independent of the concn. E. B. MILLARD.

Conductivity and viscosity of solutions of electrolytes in formamide. P. B. DAVIS, W. S. PUTNAM AND HARRY C. JONES. *J. Franklin Inst.* 180, 567-601(1915).—Four distns. *in vacuo* at low pressures were required to purify the solvent. Conductivities and viscosities of solns. of 18 inorg. electrolytes of simple type and 2 organic electrolytes have been measured at (usually) 5 concns., and temp. coeffs. of cond. and degrees of dissociation have been calcd. The most dil. soln. measured is assumed to be completely dissociated, or in some cases one more concd. This last concn. is 0.01 *N* in some cases, 0.025 *N* in some, and 0.00062 in some. HCONH_2 has a higher dielectric const. than H_2O , (94) and should show great dissociating power according to the Nernst-Thomson rule, and this was found to be the case. In every case the viscosity of the solns. in formamide was greater than that of the solvent. The association factor of HCONH_2 is 6.18, the largest molecule of any solvent used in the series of papers from Jones' laboratory. Conds. of Cs, Rb, and K salts are about the same, those of Na and Li salts are less. HgCl_2 is more dissociated in HCONH_2 than in H_2O . Salts which form hydrates were found to form solvates with HCONH_2 , and the temp. coeffs. of cond. of these solutes were greater than those of salts which were not solvated. The % temp. coeffs. are approx. proportional to the viscosities of the solns.

E. B. MILLARD.

A theory of multiple ionization. A modification of the electrolytic dissociation theory. I. Introductory and qualitative statement of the theory, with applications. F. F. HEYROTH. *J. Am. Chem. Soc.* 38, 57-65(1916).—After a statement of 5 objections to the ionic theory, H. asks: "may not amphoterism be a property common to all electrolytes?" This leads to the statement: when substances undergo electrolytic dissociation in soln. they tend to dissociate into ions in at least 2 ways, the ratio between the different ionization consts. varying from nearly 1:1 to very nearly 1:infinity, depending on the nature of the solvent, the concn. of the soln., and the av. structure of the mols. dissociating. HNO_3 may dissociate as follows: $\text{HNO}_3 \rightleftharpoons \text{H}^+ + \text{NO}_3^-$ and $\text{HNO}_3 \rightleftharpoons \text{OH}^- + \text{NO}_2^+$; and equil. exists between $\text{H}^+ + \text{OH}^- \rightleftharpoons \text{H}_2\text{O}$, and $\text{N}_2\text{O}_4 \rightleftharpoons \text{NO}_2^- + \text{NO}_2^+$. Similarly in H_2SO_4 there are the 5 sets of equilibria:

Equil. consts. are then formulated for these reactions, and the theory applied to neutralization and hydrolysis.

E. B. MILLARD.

Electrolysis of concentrated hydrochloric acid using a copper anode. F. H. JEFFERY. *Trans. Faraday Soc.* 1916(Advance copy).—The app. was similar to that employed with the Au anode, except that the app. was enclosed in a bell jar over H_2O and the electrolysis performed in an atm. of N. No Cu was deposited on the cathode, nor was there any trace of Cu in the catholyte after 6 hrs. steady current of 0.5 amp. The anolyte became slightly yellow, and there was a black deposit on the bottom of the beaker in which the expt. was carried out, also a white deposit of CuCl . The black powder was Cu from the disintegration of the anode. No Cl was formed during the electrolysis; the anolyte gave a white ppt. of CuCl on addition of H_2O . Probably the Cu was in soln. as the complex ion of H_2CuCl_3 . As the CuCl was formed toward the end of the electrolysis, the reaction may be $\text{CuCl}_2 \rightleftharpoons \text{CuCl} + 2\text{Cl}'$, or the CuCl may be formed and dissolved in the HCl without dissociating. No Cu passed to the cathode while the current was on, but if the current was off for 6 hrs., then turned on again, Cu was deposited, showing that the Cu was really in a complex anion during the first electrolysis.

E. B. MILLARD.

Influence of the metallic ion in electrolytic solutions upon the potential differences between the solutions and a metallic electrode. FLORELLA K. FINNEY. *Phys. Rev.* 6, 400-3(1915).—The base of a U-tube was filled with fresh gelatin, then the arms with the solns. to be tested, electrodes of similar pieces of the same metal were dipped into the 2 solns., and the direction of the current detd. with a galvanometer. Solns. of the nitrates, chlorides and sulfates of Na, K, NH_4 , Ba, Ca, Zn, H, Cu, Fe^{+++} , and KOH, NaOH, KBr, NaBr, Ki, NiSO_4 were used in 0.1 *N* solns. (satd. solns. of BaSO_4 and CaSO_4 were used). Electrodes of Cu, Zn, Ag, Ni, Cd, Sn, Pt and Bi were used, and the results obtained were independent of the material of the electrodes. The ions could be arranged in a series in the order in which their presence in a soln. affects the soln. tension of a metal in that soln. This series is the same as the e. m. f. series. Some irregularities were found, such as disagreement between results with KNO_3 and K_2SO_4 . No data are given.

E. B. MILLARD.

Electromotive forces in alcohol. VII. Concentration cells with calomel electrodes. EDGAR NEWBERRY. *J. Chem. Soc.* 107, 1520-6(1915); cf. *C. A.* 9, 1000, 2476.—Expts. were carried out with concn. cells in which the potentials of Hg in the H_2O and alc. solns. of NaCl which were employed in the previous work were directly compared with each other, and the results obtained were corrected for boundary potentials. The e. m. f. of the cell $\text{Hg} \mid \text{Hg}_2\text{Cl}_2 \cdot \text{NaCl}(\text{satd.}) \mid \text{NaCl}(N), \text{Hg}_2\text{Cl}_2 \mid \text{Hg}$ at $25^\circ = 0.05^\circ$ was 0.0413 v., a mean of 20 measurements between 0.0408 and 0.419; of the cell $\text{Hg} \mid \text{Hg}_2\text{Cl}_2 \cdot \text{NaCl}(\text{satd.}) \mid \text{NaCl}(0.1 N), \text{Hg}_2\text{Cl}_2 \mid \text{Hg}$ was 0.0831 v. Similar cells in EtOH with satd. NaCl and 0.004 *N* NaCl gave 0.0163 v., and with satd. NaCl against 0.002 *N* 0.0293 v. Cells of satd. NaCl in alc. against satd. NaCl in H_2O could not be measured, since diffusion caused pptn. of salt. The e. m. f. of 0.1 *N* NaCl against 0.1 *N* KCl was too small to measure, but appeared to be about 0.002 v. Corrections for boundary potentials were calcd. and applied. The transport numbers of ions other than H are the same in alc. as in H_2O , that of Cl^- in alc. HCl is about 0.30, as compared with 0.16 in H_2O . Addition of small quantities of H_2O to one side of an alc. concn. cell has a marked effect on the e. m. f. Calomel electrodes in acid alc. are not satisfactory, but serve well in alc. NaCl. The dropping electrode is untrustworthy in concd. aq. solns., and in alc. solns.; the capillary electrometer is trustworthy in both solvents for the abs. potential of Hg. The abs. potential of Hg in a satd. soln. of a salt is independent of the nature of the solvent if the ions have the same affinity for that solvent. The abs. potential of the 0.1 *N* H electrode in dry alc. HCl at 25° is 0.299 v.

E. B. MILLARD.

Potentials of the calomel and hydrogen electrodes. N. E. LOOMIS. *J. Phys. Chem.* 19, 660-4(1915); cf. *C. A.* 6, 823, 824.—Recalcn. of the results of the 1911 paper, using 0.336 in place of 0.339 as the potential of the electrode 0.1 KCl-HgCl-Hg. The degree of hydrolysis of $\text{C}_6\text{H}_5\text{NH}_2 \cdot \text{HCl}$ is 2.05% at *N*/16 and 2.81% at *N*/32; the degree of ionization of 0.25 *N* HOAc is 0.88%. In reply to McBain and Coleman (*C. A.* 8, 3141), L. states that McB. and C. have misunderstood the purpose of the investigation. Attention is called to corrections for barometric pressure which were omitted from the first paper (1911).

E. B. MILLARD.

Calomel standard cell. G. F. LIPSCOMB AND G. A. HULETT. *J. Am. Chem. Soc.* 38, 20-7(1916).—Calomel was prepd. by electrolyzing *N* HCl with a Hg anode and a c. d. of 0.02 amp. per sq. cm., in the app. previously used for Hg_2SO_4 (*Phys. Rev.* 22, 334(1906)). It was gray in color, due to the presence of finely divided Hg, and it was to the reducing action of this Hg that the improved HgCl electrode was thought to be due. A vessel of the H type was used for the cell: $\text{Cd-Hg}(10\%\text{Cd}) \mid \text{Cd-Cl}_2, 2.5 \text{ H}_2\text{O} \text{ Hg}_2\text{Cl}_2 \mid \text{Hg}$. Measurements were made by the Poggendorf compensation method, using a Broca galvanometer as zero instrument in connection with a Wolff

potentiometer. The voltage could be directly detd. to 0.00001 v. Detns. of the e. m. f. taken at 25° over a period of several months gave closely agreeing values, 0.67079 ± 0.00001 . Similar detns. at 15 and 30° were made in order to study the temp. coeff. The combination is reproducible to the 5th place, it rapidly attained a const. e. m. f. which was then steadily maintained, and no gradual decrease in e. m. f. has been noticed in any of the cells as is frequently the case with Weston cells. The total heat change accompanying the reaction which takes place in the cell was calcd. to be $Q = 30036$ cal. Other cells contg. solns. of CdCl_2 which were not satd. were also made, and it was found that the voltages were much higher, but the temp. coeff. of e. m. f. changes very little with the concn.

E. B. MILLARD.

Persistence of current in photoelectric cells after suppression of exciting light. O. M. CORBINO AND G. C. TRABACCHI. Rome. *Nuovo cimento* 10, 47-67(1915).—After the interruption of the light that strikes a photoelectric cell subject to tension, there subsists a residual current, still measurable after periods of time of the order of hundredths of a sec., and which decreases with time the more rapidly as the tension applied is higher. With tensions of about 50 volts this residual current, measured 0.05 sec. after the interruption of the light, still has a value of about 0.0035 of the normal value. The residual current is due, not to subsequent emission of ions by the metal, but to persisting presence in the cell of ions formed by impact. These, before being transferred to the electrodes, create other ions, and thus set up a retardation in the process of elimination.

Entropy in condensed substances and variation of this in change of state. S. PAGLIANI. *Nuovo cimento* 10, 5-33(1915); see C. A. 9, 3016.

S. LEVY.

Invariant, monovariant and divariant equilibria. II. F. A. H. SCHREINEMAKERS. Leiden. *Proc. Akad. Wetenschappen* 18, 531-42(1915); cf. C. A. 9, 2728.—A continuation of the discussion of the position of the curves and regions representing the mono- and divariant equil. which may proceed from an invariant point in a P - T diagram, the present discussion being confined to ternary systems. The generalizations obtained are the same as those previously obtained by S. in "Die Heterogenen Gleichgewicht," Vol. III (1), p. 218, but the manner of derivation is more simple.

GEORGE W. MOREY.

Isothermals of monoatomic gases and their binary mixtures. XVII. Isothermals of neon, and preliminary determinations concerning the liquid condition of neon. H. K. ONNES AND C. A. CROMMELIN. Leiden. *Proc. Akad. Wetenschappen* 18, 515-20(1915).—Isothermals of Ne at 0° and at 20° from 20 to 93 atm. and from 20 to 84 atm., resp., were detd., as well as parts of isothermals at temps. between -182.6° and -217.5°. The virial coeffs. at 0° and at 20° are, resp., $1: A_A, +1.0731$ and 0.99986 ; $B_A \times 10^6, +0.51578$ and 0.41334 ; $C_A \times 10^6, +0.82778$ and 1.1538 . The following vapor pressures and liquid ds. were detd.: -245.68°, p 81.62 cm.; -245.88°, 76.71 cm., d 1.204; -245.92°, 76.0 cm.; -246.66°, 60.52 cm.; 247.49°, 45.16 cm.; -248.51°, 32.50 cm., d 1.248; -248.67° (triple point), 32.35 cm. T_h was estimated by comparison with H, O, and Ar in corresponding states to be between 39.9 and 45.2° K. Cf. C. A. 8, 2515.

GEORGE W. MOREY.

Isothermals of di-atomic substances and their binary mixtures. XVII. Preliminary measurements concerning the isothermal of hydrogen at twenty degrees Centigrade from sixty to ninety atmospheres. H. K. ONNES, C. DORSMANN AND G. HOLST. Leiden. *Proc. Akad. Wetenschappen* 18, 458-64(1915); cf. C. A. 9, 988.—Preliminary measurement of the 20° isothermal of H were made with a new manometer intended to be used up to 120 atms., which was standardized at 60 atms. by comparison with a previously standardized manometer. XVIII. The isothermal of hydrogen from sixty to ninety

atmospheres. H. K. ONNES, C. A. CROMMELIN AND E. I. SMID. *Ibid* 465-72.—In this detn. the above manometer was standardized directly, and the isothermal detd. accurately from 65-100 atm. Because the results lay on a curve divergent from that represented by the formula of Schalkwijk, which represented the values of p_0 from 4 to 60 atm., the following new formula was calcd. to fit the entire range: $PV_A = 1.07621 - 0.65712 \times 10^{-3} d_A - 1.2926 \times 10^{-5} d_A^2$. Amagat's value for p_0 at 100 atm. differs from that detd. by the authors by only 0.1%. The coeff. C_A in the above equation is twice as large as is to be expected from analogy with results obtained under different conditions.

GEORGE W. MORSEY.

Further experiments with liquid helium. O. On the measurement of very low temperatures. XXV. The determination of the temperatures which are obtained with liquid helium, especially in connection with the measurement of the vapor pressure of helium. H. K. ONNES AND S. WEBER. Leiden. *Proc. Akad. Wetenschappen* 18, 493-507(1915).—In the study of the v. p. of He at very low temp. difficulty is met with in the temp. measurement. The (const. vol.) He thermometer must be filled with He under very low pressure and to the measurement of its pressure the very difficult correction for the thermal mol. pressure must be applied. This correction becomes the greatest uncertainty in the measurement at very low temp. (17° K). The correction for the thermal mol. pressure is discussed, and a semi-empirical equation for its calcn. derived. Pressures were measured both with a Hg manometer and with a hot wire manometer, otherwise the app. is the same as was previously used (C. A. 6, 6). and the results obtained are essentially the same except for the correction for thermal mol. pressure. The v. p. curve of He cannot be expressed by the Nernst formula nor adequately by the Bose-Rankin formula, even when 4 consts. are used. G. W. M.

The specific heat at low temperatures. II. Measurements on the specific heat of copper between fourteen and ninety degrees Kelvin. W. H. KESSOM AND H. K. ONNES. Leiden. *Proc. Akad. Wetenschappen* 18, 484-93(1915); cf. C. A. 9, 405.—Temp. measurements were made with a Au resistance thermometer, the app. used being similar to that of the previous communications. The sp. heat decreases more rapidly than corresponds to Debye's formula, $C_v = 464.1(T/\theta)^3$; in the liquid H region and up to 40° K. θ decreases with increasing temp., falling from 330 to 312, while with Pb θ increases up to 30° K., then decreases. Incidentally, the effect of mechanical treatment on the temp. coeff. of resistance of Cu and Pb was detd. With Cu, rolling greatly diminishes the decrease in resistance between room temp. and the b. p. of H, but annealing completely annuls the effect of previous mechanical treatment. Pb is but little affected by mechanical treatment.

GEORGE W. MORSEY.

Variation of the specific heat of solids with the temperature. A. H. COMPTON. *Phys. Rev.* 6, 377-89(1915).—An equation representing the change of sp. heat with temp. which does not involve the conception of quanta of energy has been derived with the aid of the following assumption: If the relative energy between two neighboring atoms in a solid falls below a certain critical value, the 2 atoms become "agglomerated" so that the degree of freedom between them vanishes; but as soon as the energy increases again above the critical value, the degree of freedom reappears. The term "agglomeration," suggested by Benedicks, is used to indicate any state of association of the atoms on account of which degrees of freedom for thermal motion disappear. The formula is $C_v = dU/dT = 3NR\epsilon^{-1/T} + (3NR\tau/T)\epsilon^{-\tau/T} - (3N\gamma\tau/T^2)\epsilon^{-\tau/T}$, where $3N$ is the greatest possible number of degrees of freedom, γ is the potential energy of each agglomerated degree of freedom, $\tau = \epsilon/2R$ and ϵ is the critical value of the energy below which a degree of freedom remains agglomerated, T is the abs. temp., R is the gas const. for a single mol., and e the base of natural logs. Comparison with exptl. data shows a satisfactory agreement between the equation and values

detd. by expt. The strong support of the exptl. values seems to indicate that the agglomeration hypothesis represents more accurately the condition of the atoms in a solid than does the quantum hypothesis. Debye's expression for the variation of sp. heat with the temp. was found to be largely empirical, and the present comparison was made with the equation of Einstein. The defence of the assumption on which the derivation is based is reserved for a future paper.

E. B. MILLARD.

Some sources of error in viscosity measurement. E. C. BINGHAM, H. I. SCHLESINGER AND A. B. COLEMAN. *J. Am. Chem. Soc.* 38, 27-41(1916).—Viscosities detd. in the viscosimeter of Bingham (*C. A.* 8, 1525) when calcd. from the formula $\eta = Ctp - C'p/t$ were not const., but varied when the applied pressure (p) was varied. In the formula t is the time of flow, η the viscosity, ρ the density, and C and C' are consts. A math. discussion showed that the av. pressure may be substituted in the viscosity formula, provided this is correctly calcd., and that deviations from the Ostwald formula $\eta = \eta' \rho t / \rho' t'$ are due to not taking into account the loss in kinetic energy, and not to any failure to recognize the true value of the av. pressure. Values of viscosity calcd. from the equation derived were in agreement with observed values for H_2O , $HCOOH$, and sugar solns. It was of no consequence whether the capillary was horizontal or vertical. There is a definite loss of kinetic energy when a liquid flows from a capillary with a trumpet-shaped end, but whether this kinetic energy correction is the same as in the case of a capillary with uniform bore is not proved. The capillaries should have ends as nearly square as possible (so the kinetic energy correction may be calculable) and the bulbs should be as short as possible and approx. the shape of 2 cones placed base to base.

E. B. MILLARD.

Viscosity and density of molten metals and alloys. M. PLÜSS. Basel. *Z. anorg. allgem. Chem.* 93, 1-45(1915).—Expts. on the viscosity of some metals and alloys were made, using the capillary tube method. The app. used was a long capillary tube, to which was sealed a bulb and a tube leading to an air pump. The capillary tube was dipped into the liquid metal, the bulb and part of the upper tube filled with metal by suction, and the time of outflow between 2 marks on either side of the bulb detd., either optically or by an electrical method. At high temp. the entire tube and melt were held in an electrically heated furnace; at lower temp. a vapor bath was used. When easily oxidizable metals were studied the furnace was filled with H. The abs. vol. of the tubes and bulb were detd. by weighing, and the app. was calibrated by expts. at 18° with Hg. The accuracy of the result for abs. viscosity, which was calcd. from the time of flow and the dimensions of the app., is believed to be $\pm 0.14\%$; the relative detns. should have a higher accuracy. Emphasis is laid on the correction for the change in level of the metal in the crucible, due to the metal flowing out of the tube. The viscosity of Hg was detd. from 0 to 299° ; the results obtained are 1-1.5% lower than those of Koch below 80° ; above this temp. P.'s results are higher, the difference increasing to 4% at the highest temp. Neither the fluidity nor the viscosity curves are linear with temp. Measurements were made on Sn from 280 to 389° , and on Bi from 280 to 365° ; in both cases both the fluidity and viscosity curves are linear. Viscosity and density detns. were made on several alloys, the latter by a displacement method. The viscosity of molten Pb at 280° is about 0.03, and that of all the Pb-Sn alloys is higher. The viscosity-compn. curve rises to a max., then falls to a min. at the eutectic compn., then rises to that of pure Sn. The Pb-Sb system was only studied over the interval 7.6-17.0% Sb; the viscosity curve shows a strong min. at the eutectic compn. In the Sn-Bi system 2 max. were found on the viscosity curve, corresponding to the compds. $BiSn_2$ and Bi_2Sn , and a min. at the eutectic compn. In none of the above alloys was there any relation between the viscosity and the density, and the viscosity does not even approx. follow the mixt. rule. The results of Arpi

(C. A. 8, 1406) are discussed, and the difference between his results and those of P. are ascribed primarily to neglect of the above correction for the change in level of the metal height in the reservoir.

GEORGE W. MORREY.

Coexistence of phases subjected to different pressures. RUD. WEGSCHEIDER. Vienna. *Z. anorg. allgem. Chem.* 93, 95-6(1915).—W. points out that the formula derived by Niggli (C. A. 9, 1863) showing the influence of differential pressure on a heterogeneous equil. can be derived in a less general manner from relations previously derived by W. (C. A. 6, 1874.)

GEORGE W. MORREY.

Comparative method for determining vapor densities. PHILIP BLACKMAN. *J. Chem. Soc.* 107, 1500-3(1915).—A drop of Hg placed in the middle of a capillary tube about 100 cm. in length separates the 2 substances, the vapor d. of one of which must be known. A small column of each of the liquids is placed in the tube, one each side of the Hg, and both ends are sealed off. The quantity of each liquid present is detd. by measuring the length of the capillary column. From these lengths, and those of the air columns at room temp., the lengths of the vapor spaces when the tube has been heated to a high enough temp. to vaporize both liquids, and the known ds. of the substances, the vapor densities were calcd. by a complicated formula. A simplified formula gave nearly as good agreement. Observed densities agreed with calcd. ones to within better than 9% in the cases given, and was quite close for some liquids.

E. B. MILLARD.

Effective resistance and inductance of iron and bimetallic wires. J. M. MILLER. Bur. Standards, *Bull.* 12, No. 2, 207-67(1915).—A formula has been derived which permits the exact permeability curve of a homogeneous Fe wire for circular magnetization to be obtained from measurements of the self-inductance of the wire with direct current. Detns. and comparisons of axial and circular permeability curves were made for a number of wires, in some of which there was fair agreement with the calcd. values, and in others considerable variations which were possibly due to non-homogeneity or non-isotropy of the material. The effective resistances of several samples of Fe telegraph and telephone wires were detd. for 0.5 to 10 amp. in the range of frequencies 50 to 3000 cycles per sec., and the exptl. results extrapolated to zero current. Formulas for the resistance of bimetallic wires are given, together with some exptl. material on Cu-steel wires.

E. B. MILLARD.

The blue color of the sky and the constant of Avogadro. D. PACINI. *Nuovo cimento* 10, 131-67(1915).—In studying the deviations of the law of Rayleigh relating to the absorption of solar radiation by the air, numerous expts. were made looking to spectrophotometrical comparisons between the light of the sky and that of the sun at an altitude of 1090 m. No indications were obtained that at this altitude the air shows a condition of greater purity. Rayleigh's law connecting the ratio c/s (c being the intensity of the light of the sky and s that of the sun) with Avogadro's const. N (the number of molecules per gram-mol. at 0° and 760 mm.) is: $c/s = 22390 \times 13.6 H \pi^3 (k - 1)^2 t^2 \varphi (1 + \cos^2 \beta) / 2 \times 0.00129 \cos s \lambda^4 N$; k = dielec. const. of the air, φ = the apparent diam. of the sun, β = angle which the direction of the sun makes with that of the region of the sky under observation, s = the zenithal distance of the latter direction, H = the barometric height at 0° . In order to compare the results with those obtained by preceding observers, there was calcd. for every observation the mean value of the exponent n , using the factor $1/\lambda^n$ instead of $1/\lambda^4$ in the formula. Curves were plotted from the data of each observation based on individual wave lengths, and were divided into different types when compared with the theoretical curve. P. discusses at length the conditions and probable causes detg. the deviations of the state of the atm. from what would be an ideal turbid mean. The calcn. of Avogadro's const. N from the data obtained showed that with the purest sky, the values of N were always

lower than those deduced from other methods; a mean value of 57×10^{22} was found, which may be considered as the minimum value of N , but which indicates that the blue color of the sky is due to the mol. structure of the atm. S. LEVY.

Fluorescence of solutions. G. LÉPINE. *Ann. phys.* 4, 207-28(1915).—Expts. on the influence of concn. on the fluorescence of rhodamine and fluorescent blue in H_2O , and phenosafranine in alc. have been made, and diagrams drawn showing the change in fluorescence with the concn. Other solvents were used with 5 fluorescent substances; the solvents were alcohols, HOAc, acetone, ether, $CHCl_3$, C_2H_5Br , glycerol, etc. For very small concns. in H_2O the fluorescence was proportional to the concn., but the intensity increases more rapidly than the concn. above 10^{-4} . The same substance in different solvents may show a variation of intensity of fluorescence of 1:15. Fluorescent solns. absorb the radiations which excite them. E. B. MILLARD.

The fluorescence of sulfur, selenium and tellurium vapor. D. DIESTELMEIER. *Z. wiss. Phot.* 15, 18-55(1915).—Tables and figures are given, S, Se and Te heated to vapor in hard glass or quartz containers and excited by various arcs and sparks, etc., fluoresce with selective absorption. Impurities in the vapors show marked effects. The fluorescence consists of band spectra shaded to the red, and depends upon the kind of exciting light used. The absorption spectra (bands shaded to red) were measured for different vapor densities. The fluorescence spectra in general overlap or coincide with the absorption spectra. The double at. mols. are regarded as the emission centers of fluorescent light. Thus for S the max. fluorescence occurs at 500 to 550° at which $S_8 \rightarrow 4S_2$. At 650 to 700° further dissociation $S_2 \rightarrow 2S$ takes place and the intensity of the fluorescence diminishes. PAUL D. FOOTE.

New fluorescence spectrum of ammonium uranyl chloride. E. L. NICHOLS AND E. MERRITT. *Phys. Rev.* 6, 358-76(1915); cf. *C. A.* 6, 1397; 9, 3020.—Triclinic plates of $UO_2Cl_2 \cdot 2NH_4Cl \cdot 2H_2O$ were strongly fluorescent, and the fluorescence spectrum, unlike that of other uranyl salts, is resolved at room temp. into at least 8 groups of narrow bands. Each group, which corresponds to a single band of the usual uranyl fluorescence spectrum, consists of 5 nearly equidistant bands. The bands, while not so narrow as some of the line-like bands of the uranyl spectra at the temp. of liquid air, are well sepd. from their neighbors, and about 18Å in width. A detn. of the distribution of intensities within the visually brightest group (5302 5114) was made with the spectrophotometer as follows: 5302 intensity = 18, 5253 = 33, 5203 = 24, 5157 = 11, 5114 visible but too faint for measurement. Tables are given of the positions of bands at 20°, of shifts between this temp. and -185°, av. intervals between homologous bands, calcd. and observed frequencies of the various series of bands, and of the absorption spectrum at 20°; also tables showing the fluorescence and absorption bands arranged in series at -185°. E. B. MILLARD.

The structure of the ultraviolet absorption spectra of benzene derivatives. RUDOLF WITTE. *Bonn. Z. wiss. Phot.* 14, 347-92(1915).—Using a quartz spectrograph, and as a light source an Al spark under H_2O , the absorption spectra were measured in the region about $\lambda 2200$ to $\lambda 3000$ for vapors of benzene, toluene, chlorobenzene, bromobenzene, aniline, phenol, anisole. No selective absorption was found for iodobenzene, nitrobenzene, and benzoic acid. The wave lengths are tabulated together with intensities, and the bearing of the data upon series grouping is discussed at length. PAUL D. FOOTE.

The passage of light through the slit of a spectroscope. P. ZEEMAN. *Leiden. Proc. Akad. Wetenschappen* 18, 412-30(1915).—Errors in spectroscopic measurements are caused by polarization of light passing through a narrow slit (*C. A.* 7, 1839). Z. has detd. that at the following widths of slit the 1st extinction of the horizontal vibra-

tions becomes apparent: Hilger const. deviation spectroscope, green light, 0.010 mm.; eschelon spectroscope, red light, 0.0017 mm.; green light, 0.0015 mm. With white light the image formed by the horizontal vibrations becomes fainter and of a bluish tinge as the slit is narrowed.

3. RADIOACTIVITY.

WILLIAM H. ROSS.

The life of radium. ELLEN GLEDITSCH. Univ. Kristiania. *Am. J. Sci.* 41, 112-24(1916).—An exptl. detn. was made of the life of Ra by Boltwood's method (*C. A.* 2, 3193) which consisted in sepg. the Io from known quantities of U minerals and comparing the amts. of Ra produced by the sepd. Io in known periods of time with the amts. of Ra associated with it in the minerals. That the life of Io is sufficiently long to give an accurate value for the const. of Ra as detd. by this method was shown by the fact that the rate of growth of Ra in an Io soln., prepd. nearly 7 yrs. ago, was found to have remained const. throughout the entire interval. In carrying out the method all the rare earths contained in the mineral soln. were pptd. and removed by filtration. To the soln. was added a soln. of a small quantity of rare earths containing no Ra nor Io, and the pptn. was repeated. After filtration a new quantity of rare earths was brought into the soln. and pptd. The first 2 ppts. were put together, ignited to the oxides and converted into the sulfates. The hydroxides were then pptd. several times to remove Ra, and finally dissolved in dil. HCl to form the main soln. The 3rd ppt. was treated separately, but in exactly the same way and used as a test soln. which, when no growth of Ra took place in it, showed that all Io had been removed and was in the main soln. The minerals examd. were uraninite (North Carolina), cleveite (Norway), and 2 specimens of very pure bröggerite (Norway). The values obtained in the case of each mineral for the transformation const. of Ra are, resp., 3.7, 3.9, 4.2 and 4.1×10^{-4} (yr.)⁻¹. The corresponding half-value periods are 1,836, 1,780, 1,640 and 1,670 yrs. The values given for the 1st 2 detns. are considered less trustworthy than those for the last 2, which agree closely with one another, and with the value 1,690 yrs., calcd. by Rutherford (*C. A.* 8, 3753) from the number of α -particles emitted per sec. per g. of pure Ra.

Electrothermic smelting of iron ores in Sweden. A. STANSFIELD. Canada Dept. of Mines, Mines Branch, *Bull.* 344, 57 pp.—A report on the commercial operation of the electrothermic Fe-smelting furnaces in Sweden. Two main types of furnace are described: (1) The Elektrometall furnace in which the ore is preheated and partially reduced in a shaft by circulation of the furnace gases. (2) Furnaces of the Helfenstein, Californian, and Tinfos type in which there is no provision for preheating. Numerical data for the Elektrometall furnace are given which show the charge, heat distribution, and efficiency. The heating value of the furnace gases is 75% of the whole elec. supply. The circulation of the gases caused a saving per ton of iron of 35.2 kg. of coke (11% of the whole) and 152 kw. hrs. (7% of the whole), but the escaping gas is poorer in heating power by 340,000 cal. (23% of the whole). These furnaces have a daily output of 20 or 30 tons but on account of the large stack it would be impracticable to increase the size of the unit to 100 tons. If this could be done with the Helfenstein furnace, the gain in efficiency due to increased size would probably more than offset the absence of circulation. Detailed descriptions of various Swedish works are given together with figures for the consumption of elec. energy, charcoal or other fuel, fluxes and electrodes, and cost of plant and upkeep. There is no evidence to show that elec. Fe smelting can be undertaken on a large scale in competition with the existing blast-furnace industry in Canada. The cost of producing elec. pig iron in Canada is estimated at from \$18.50 to \$21.00 per 1000 kg. The report concludes with a description of the Rennerfelt elec. steel furnace. E. SCHRAMM.

Electrolytic copper. B. WELBOURN. *Engineering* 100, 524-5 (1915).—W. describes briefly the methods in use in the U. S. for the smelting of Cu ores, for electrolytic refining and for the manuf. of Cu wire. The Engineering Standards Committee definition of hard drawn Cu wire is wire which does not elongate more than 4% on a length of 10 inches and which has a resistance 2% higher than annealed Cu at 15.6° (60° F.). A satisfactory definition should cover tensile strength, elongation, limit of proportionality, modulus of elasticity (in exceptional cases) and ohmic resistance. In practice it is found that the tensile strength increases proportionately to the diam. and not to the sectional area. Some expts. indicate that the increased strength of hard drawn wire does not lie entirely in the outer skin as is commonly supposed. E. SCHRAMM.

Bronzing processes suitable for brass and copper. T. I. BAKER, SR. *Metal Ind.* 13, 464-5, 501 (1915).—A collection of practical bronzing formulas depending upon chem. and electrochem. actions for the production of color films. A summary is also given of expts. made to det. the weight per unit area for various color films, and the loss of metal per unit area incurred in the coloring process. Results are given for black and brown Cu oxide films obtained by dipping in solns. of various Cu salts, also for a black NiS film obtained electrolytically from a Ni soln. containing Zn and thiocyanates. The wt. of the color film ranged between 21.5 and 99 mg. per sq. dm., while the loss of metal, as detd. by weighing before bronzing and again after removing the color film, varied from 44 to 83 mg. per sq. dm. F. A. STRAUSS.

The Cumberland electrolytic process for preventing corrosion of all metals immersed in liquids. ELLIOTT CUMBERLAND. *Trans. Faraday Soc.* 1916 (advance copy), 4 pp.—After a brief review of the investigations of Whyte, Philip, *et al.*, C. describes what has proved to be the only effective method of overcoming the loss of Zn from condenser tubes: Pieces of Fe, serving as anodes (the body of the condenser is cathode) are suspended in the liquid and suitably insulated from the vessel to be protected. A small dynamo supplies d. c. at 10 v. All corrosive action is transferred to the Fe anodes which must be renewed about once in 2 yrs. This C. system has been employed for years in all types of steamships and in many large power plants. A further advantage of the system is the prevention of boiler scale. Two cuts are shown.

MAYNARD, G. S.: List of References to Storage Batteries. New York: Public Library. 37 pp.

Electrolyzing zinc solutions. C. A. HALL. U. S., 1,163,911, Dec. 14. The free anion concn. of the electrolyte, *e. g.*, ZnSO₄ or ZnCl₂ soln., is maintained const. during electrolysis by adding finely divided CaCO₃ to the electrolyte and agitating to combine with the liberated anions and form an elec. inert compd.

Electrolytic production of alkali metal and alkaline earth metal nitrogen compounds. E. A. ASHCROFT. U. S., 1,163,498. Dec. 7. NaCl or NaOH or other Na compd.

is electrolyzed over a Pb bath to form a Na alloy with the molten Pb and the alloy formed is electrolyzed in a second cell as anode with an electrolyte of the desired product (Na amide, cyanamide or cyanide) to which NH_3 is supplied to form amide or NH_4 and C to form cyanamide or cyanide, the temps. of the second cell being 250–350°, 500° and 800°, resp., for the formation of these three compds. Hg, Sn or an alloy may be used instead of Pb.

Carbon-zinc-chlorine primary electric battery. H. E. R. LITTLE. U. S., 1,163,834, Dec. 14. Structural features. Cf. C. A. 9, 179.

Primary electric battery. G. A. LUTZ. U. S., 1,163,163, Dec. 7. An annular sheet Fe or Cu receptacle with minute slits in its walls is used to hold the depolarizer, *e. g.*, Cu oxide, in alk. batteries such as the Gordon battery. Cf. C. A. 10, 154.

Treating lead storage battery plates. C. C. CARPENTER. U. S., 1,164,464, Dec. 14. Pb battery plates are rendered more durable and resistant to charging and discharging of the battery by treatment with a soln. of Ba persulfate which oxidizes the Pb of the plate and forms BaSO_4 which is diffused throughout the plate.

Storage battery plates. W. S. O'CONNOR. U. S., 1,164,746, Dec. 21. Structural features.

Electric furnace for treating molten iron or steel. C. HERING. U. S., 1,162,773, Dec. 7.

Tungsten filaments for incandescent electric lamps. T. A. EDISON. U. S., 1,163,329, Dec. 7. W is vaporized by an elec. discharge *in vacuo* and deposited on a revolving glass drum in the path of the discharge, then stripped from the drum and cut to the desired shape and size, or shaped on wax or metal of low m. p. which can be sepd., by fusion, from the W.

Arc-light electrode. I. LADOFF. U. S., 1,164,728, Dec. 21. An arc-light electrode containing at least 60% of C is made with 30–40% of Ba titanate, which gives a white flaming arc of high c. p. Titanates of Al, Mg, Ce and Th and Ti borate give similar results.

Electric ozone generator. M. P. OTTO. U. S., 1,163,768, Dec. 14.

Ozonizer; sterilizing liquids. H. GRUNER. Brit., 18,025, July 30, 1914. The ozonizer (see C. A. 9, 761) may be used for sterilizing liquids, *e. g.*, the liquid may be supplied through a nozzle into the injector chamber, so as to induce a current of ozonized air through the generator. The liquid and gas pass into and are mixed in a chamber which is provided with an inner member having a recess into which the liquid and gas pass to assist mixing. Cf. C. A. 9, 761.

Arc lamps; vacuum tubes. H. GREINACHER. Brit., 18,149, July 31, 1914. Electrodes of material not conductive when cold and not readily scattered, *e. g.*, a mixt. of zirconia or thoria or yttria, are supported within a bulb by tubes of glass, SiO_2 , etc., through which pass leading-in wires. A small gap is left at the inner end of each tube, or the electrodes themselves are tubular, so that a discharge passes first between the leading-in wires and then between the electrodes, which incandesce in consequence of their resistance. A high elec. pressure, say 2000 v. a. c., is used. The bulb may contain dry air, at a pressure of 5–20 mm. Hg, or may be filled with another gas such as N. Such lamps may be connected directly to overhead lines for street lighting. Reference is made to the use of C or metal filaments as cathodes.

Effecting chemical reactions with an extended arc. H. ANDRIESSENS and J. SCHNEIDEMANDEL. Ger., 285,111, June 24, 1913. Addition to 284,341 (C. A. 9, 3178).

5. PHOTOGRAPHY.

L. DERR.

Dichroic fog. E. COUSTET. *Rev. gén. sci.* 26, 599-600(1915).—Dichroic fog formed during development is always a surface effect; when produced in the fixing bath it extends through the film. It is usually caused by hypo, KCNS or NH_4CNS or other AgBr solvents in the developer, or by any Ag salt dissolved in the developer, or by developer in the hypo bath. High temp. and prolonged development favor its formation, and thick films are more prone to it than thin ones. Its prevention is accomplished by keeping hypo out of the developer, by washing off all developer from the plate before fixing, and by using an acid hypo bath which is to be discarded before complete exhaustion. It can be removed by a bath of 1:1000 neutral KMnO_4 , followed by diluted commercial NaHSO_3 liquor; or by a bath of water 100 cc., CuSO_4 3 g., NaCl 3 g.

RHODES, H. J.: *The Art of Lithography*. New York: Van Nostrand Co. 344 pp. \$3.50.

Color photography. C. L. A. BRASSEUR. U. S., 1,163,207, Dec. 7. A positive is printed on a surface with red, green and blue-violet lines (or other subdivisions) by means of pure red, pure green and pure blue-violet light, using a negative with orange, yellowish green and violet-blue subdivisions.

Photography. O. DODGE. Brit., 18,298, Aug. 7, 1914. Process of producing a planographic or intaglio printing surface without sensitizing, which is applicable alternatively for ornamenting surfaces. A flexible paper base which has been floated upon a soln. of dextrin, albumin, and starch, is coated with a gum or gelatinous film and sensitized with dichromate. After exposure to the printing-negative, the film is damped by floating upon H_2O and transferred on to a transfer surface, using gentle pressure only. The exposed portions remain adhering to the flexible paper base, and the unexposed portions are transferred. The film is inked and is subsequently removed together with the ink thereon, leaving the design on the transfer surface where the surface was exposed. Gradation in the design may be obtained by breaking up the image of the printing-negative with a large or small dot or grain. Alternatively to preparing the surface with the design on as a printing-surface, the design may be used for ornamenting purposes.

Applying gelatin to glass for copying processes. ROTOPHOT, AKT.-GES. FÜR GRAPHISCHE IND. Ger., 284,805, Jan. 18, 1914. A piece of com. gelatin paper (paper with colorless gelatin coating) is sensitized as a pigment paper in the chromate bath, and dried. The entire surface of the sensitized paper is then exposed for a short time to natural or artificial light, and then softened in H_2O and applied as in the pigment process. After removal of the paper the film is developed with hot H_2O , whereby a layer of gelatin of uniform thickness is obtained which is insol. in hot H_2O and serves the purposes of the processes.

Photographic pictures in blue tones. FARBW. v. M. L. & B. Ger., 284,423, Feb. 24, 1914. The black pictures obtained according to 283,149 (C. A. 9, 2842) are converted into blue tones by the action of oxidizing agents. Photographic reducers serve as oxidizing agents, e. g., alkali ferricyanides, alone or in admixt. with Ag solvents such as $\text{Na}_2\text{S}_2\text{O}_3$ or KCN, also CuO-NH_3 soln., Fe_3Cl_6 soln., etc. Farmer's reducer

is preferred (fixing soln. with some $K_3Fe(CN)_6$). The process is especially suitable for the production of cinematographic films in blue tones. After treatment with Farmer's reducer the picture is washed thoroughly in running H_2O and dried.

The thermal dehydration of stilbite, thaumasite, and the hydrates of magnesium sulfate and copper sulfate. H. E. MERWIN. *Z. Kryst. Min.* 55, 113-4(1915); see C. A. 9, 31. E. T. WHERRY.

Preparation of pure uranium and other metals. W. I. BARAGIOLA. *Schweiz. Apoth. Ztg.* 53, 477-8(1915); cf. C. A. 8, 2855.—A claim of priority. B. describes his prepn., in 1903-4, of U by chlorinating U_2O_5 with CO_2 and CCl_4 and reducing UCl_4 with Na. Kahlbaum and B. also prepd. chem. pure Cu by very slow distn. of electrolytic Cu in the vacuum of a Hg pump, each distn. consuming weeks. The Cu finally became faintly pink. S. WALDBOTT.

Separation of the rare earths giving the more soluble double sulfates from Brazilian monazite sand. C. JAMES AND A. J. GRANT. *J. Am. Chem. Soc.* 38, 41-7(1916).—The rare earth sulfates were treated with K_2SO_4 in smaller quantity than that required for complete pptn. of the Ce metals, and the soln. was then pptd. with oxalic acid. These oxalates were ignited to oxides in a coke-fired furnace, dissolved in HNO_3 , $Ce(NO_3)_3$ was reduced by adding some of the original oxalates, and the filtered soln. treated with slightly less than the theoretical amt. of HNO_3 which had been neutralized with magnesite. Since the soln. in HNO_3 took place with violence, the content of Ce could not have been large. Fractional crystn. of the double nitrates with Mg gave results which are shown in a large table. Details are given of the sepn. of Ce, La, Pr, Nd, Sa, Eu, Gd, Tb, Dy, Ho, and Yt, but in such a condensed form as to need no further abridgment. E. B. M.

Action of hydrogen sulfide on arsenic acid. WILLIAM FOSTER. *J. Am. Chem. Soc.* 38, 52-7(1916); cf. Usher and Travers, *J. Chem. Soc.* 87, 1370(1905).— As_2O_5 is never reduced directly to As_2O_3 and free S by H_2S as stated by Rose (*Ann. Phys. Chem.* 107, 186(1859)). When H_2S reacts with As_2O_5 the first product is H_3AsO_4S , which is somewhat unstable; in the presence of dil. acids it breaks down slowly to As_2O_3 and S and in the presence of high concns. of acid it is still more unstable. Concd. HCl brings about the decompn. *very quickly*, even at 0° . When solns. of As_2O_5 are treated with a *rapid* stream of H_2S , no reduction takes place, even if no mineral acid is present. As_2O_5 satd. with H_2S yielded pure As_2S_3 after the soln. had stood 91 hrs. No reduction occurred in solns. of As_2O_5 in the presence of HCl ranging in concn. from 0.9 to 32%, when solns. were treated at 15° with a *rapid* stream of H_2S . These conclusions are based on qual. and quant. expts. which have been made, but only a few of which are given in the article. E. B. MILLARD.

Application of cryoscopy to chemical analysis. M. DRAPIER. *Compt. rend.* 161, 461-3 (1915).—Cryoscopic methods may be used for detg. the concn. of a particular constituent of an org. mixt. under favorable conditions. GEORGE W. MOREY.

Nephelometry (photometric analysis). I. History of method and development of instruments. P. A. KOBER AND S. S. GRAVES. *J. Ind. Eng. Chem.* 7, 843-7 (1915).—A brief general discussion is given and different nephelometers are described. K. and G. have designed a new instrument, the optical workmanship of which is based on the Dubosq colorimeter. The advantages of the new instrument are increased accuracy and the fact that it can be used as a colorimeter. The cost is \$36. The article is illustrated with many figures. E. W. BOUGHTON.

Qualitative microanalysis. F. EMICH. *Z. anal. Chem.* 54, 489-502 (1915).—A description of some of the methods of qual. microanalysis (no new material).

GEORGE W. MOREY.

A rapid precise standardization of acid solutions. MERLE RANDALL AND CHAS. C. SCALONZ. Univ. of Cal. *Met. Chem. Eng.* 13, 787 (1915).— Na_2CO_3 can easily be obtained of sufficient purity for standardizing acid solns., with the exception of the H_2O content. Since Richards and Hoover (*C. A.* 9, 734) have shown that Na_2CO_3 can be completely freed from H_2O without decompn. by fusion in an atm. of CO_2 , the main objection to its use as an acidimetric standard has been removed. The fusion in CO_2 can be easily carried out in a Pt crucible fitted with a Rose crucible cover and delivery tube. The subsequent operations are obvious. GEORGE W. MOREY.

The separation and estimation of aluminium and beryllium by use of acetyl chloride in acetone. H. D. MINNIG. Yale Univ. *Am. J. Sci.* 40, 482-5 (1915).—The method is similar in all details to that previously described for the sepn. of Al and Fe (*C. A.* 9, 771). Because of the slight solubility of BeCl_2 , the mixt. of AlCl_3 and BeCl_2 should not exceed 0.15 g. in wt., and should contain less than one third BeCl_2 . A double pptn. is required for the Al-Be sepn., and even then the Al_2O_3 tends to carry down BeO .

G. W. MOREY.

Volumetric determination of cerium by means of potassium permanganate. VICTOR LENHER AND C. C. MELOCHE. *J. Am. Chem. Soc.* 38, 66-70 (1916).—The reaction studied was $6\text{Ce}(\text{NO}_3)_3 + \text{K}_2\text{Mn}_2\text{O}_8 + 4\text{H}_2\text{O} = 4\text{Ce}(\text{NO}_3)_4 + 2\text{Ce}(\text{OH})_4 + 2\text{KNO}_3 + 2\text{MnO}_2$; in addition to the $\text{Ce}(\text{OH})_4$ formed in this reaction, the nitrate undergoes hydrolysis with the formation of more $\text{Ce}(\text{OH})_4$ and HNO_3 which tends to reverse the reaction. Some suitable neutralizing agent must be used to take up this acid. In the first series, standard $\text{Ce}(\text{NO}_3)_3$ was dild., an excess of ZnO paste was added, then most of the KMnO_4 in the cold, after which the soln. was brought to boiling, and the titration finished hot. Under these conditions a coarse granular ppt. was obtained which settled readily. The end point was sharp, and its permanence was tested by boiling the soln. for a minute after finishing the titration. Agreement within 0.0003 g. was obtained in the ZnO series, whether the whole titration was performed hot or only the end of it. Results with CaCO_3 were as accurate, but the reaction proceeded slowly, so that this neutralizing agent is not recommended for practice. Milk of magnesia was found to be one of the best neutralizing reagents. Satisfactory results were obtained with soluble reagents when too great an excess is not used. Borax (satd. soln.), NaHCO_3 , Na_2CO_3 gave good results, (low with Na_2CO_3), but NaOH , KOH , $\text{Ba}(\text{OH})_2$, NaOAc , Na_2SiO_3 , Na_2PO_4 , Na_2HPO_4 , Na_2WO_4 and Na_2AsO_4 were not satisfactory. The method is applicable to Ce^{III} in the presence of Ce^{IV} . E. B. M.

New method for the iodometric estimation of vanadium. HUGO DITZ AND FRIEDRICH BARDACH. Prague. *Z. anorg. allgem. Chem.* 93, 97-137(1915).—The method is based on the reduction of V_2O_5 to V_2O_4 in a small vol. by HCl and KBr, and iodometric titration of the liberated Br, after diln. The reduction and titration are carried out in a 1.5 l. flask fitted with a ground stopper carrying a separatory funnel and an absorption tube for retaining the evolved Br vapor in KI soln. The effect of various factors on the method was detd. using NH_4VO_3 soln., whose content of V_2O_5 was detd. by ignition; because of a V content less than the theoretical the V_2O_5 so obtained was tested by reduction to V_2O_4 with H, and found to be pure. Expts. showed the reduction of V_2O_5 solns. in the cold by HCl to be negligible, but HCl plus HBr gives complete reduction to V_2O_4 , without danger of V_2O_5 formation. HCl and KI give irregular results, at times higher than correspond to reduction to V_2O_4 , probably due to a secondary reaction with the air; dil. HI solns. are without action on V_2O_4 . A systematic study of the effects of varying various factors showed the following to be the best method of carrying out a detn. To 25 cc. of the V_2O_5 soln. contained in the above app. add 10 cc. 10% KBr soln. and 75 cc. concd. HCl, let stand 5 min., dil. with H_2O to 1 l., wash the KI soln. in the absorption tube into the app., add 20 cc. 5% KI soln., and titrate I with $Na_2S_2O_3$. H_2SO_4 can be substituted for HCl, but more is needed and an hr. is necessary for the completion of the reaction. GEORGE W. MOREY.

Determination of mercury in cyanide solution and precipitate. W. J. SHEARWOOD. *Mining Sci. Press* 111, 663-5(1915).—In cyanide soln.: Measure 1000 cc. soln. into a 2500 cc. acid bottle, give the contents a rotary motion, then add 0.5 g. of finest Al powder. After shaking violently for $\frac{1}{2}$ min. and ending with a rotary motion allow to stand 1 min. Repeat the above method of agitation at least 6 times. Shake the soln. and transfer to a 1000 cc. narrow-necked flask. Invert the flask over a Gooch filter $\frac{1}{2}$ inch below the rim, clamp it in position and filter with a good vacuum. After all particles have been transferred to the filter rinse once with H_2O , once with alc., then twice with a little ether. Heat the crucible gently until completely dry, transfer filter pad and contents to a Whitton app. for detn. of Hg. Using 1000 cc. of soln. every mg. corresponds to 1 part per million. If the soln. is very low in alkali or cyanide add 1 g. NaOH. In cyanide ppt.: Place weighed sample in a covered 150 cc. beaker and add 10 or 15 cc. dil. HCl. Add more HCl and heat until action slackens. Dilute with warm H_2O , stir, allow to settle and filter through a Gooch crucible using gentle suction. Heat the residue with a little more acid, dilute and filter as before. Transfer the residue to the filter, wash with hot H_2O until free from all chlorides, suck dry, wash once with 10 cc. alc., then at least twice with ether. The residue contains all the Hg. Transfer the residue with asbestos mat to the Whitton app. containing a weighed disk of Ag or Au foil. Add 5 g. clean Fe filings or crushed steel and a little well burned CaO to the residue and grind the whole. Cover with 2 or 3 g. Fe or CaO. Clamp the foil and cooler upon the retort and heat for 20 min. as with ores. Weigh the foil with condensed Hg. The Whitton app. is a flanged, wide-mouthed retort turned from a piece of mild steel. The cover is a Ag or Au foil, preferably Au, cooled by a flat-bottomed brass dish of H_2O , the whole system being connected by a clamp engaging a steel plate with a hole in which the crucible fits.

L. P. WEBBERT.

Nephelometric estimation of phosphorus. A correction. P. A. KOBER AND G. EGERER. *J. Am. Chem. Soc.* 37, 2373-81(1915); *C. A.* 9, 2855.—In the original abstract instead of "the reagent of Pouget and Chouchak" should be read "a modified reagent of Pouget and Chouchak contg. HCl in place of HNO_3 ." E. B. MILLARD.

Estimation of selenium in sulfur. W. SMITH. *J. Ind. Eng. Chem.* 7, 849-50 (1915); cf. Denigès, *C. A.* 9, 1287.—Weigh about 50 g. of finely ground S into an Erlen-

meyer flask and add a few more cc. of Br than g. of S taken; allow to stand 15 min. Transfer to a 100 cc. sepg. funnel and shake vigorously with 40 cc. Br water for 1 min.; sep. the S_2Br_2 from the aq. soln. and pour the latter through a wetted filter paper. Add about 2 cc. of Br and 40 cc. Br water to the S_2Br_2 and repeat the extn. 4 times, the last ext. being kept separate. If S seps. during extn. add more Br. Boil the solns. (the combined first 3 extns. and the last) till clear and remove any free Br by addition of K_2SO_4 until soln. is just colorless. The Se may commence to ppt. at this stage. Dil. to about 250 cc., add 15 cc. HCl and about 5 g. KI, and boil. Proportionately less HCl and KI are added to the last extn. Se is completely pptd. and is gradually converted to the black allotrope. Remove free I with a few cc. of K_2SO_4 soln., boil for 20 min., filter through a tared Gooch crucible, wash the Se with hot H_2O and dry to const. wt. at 100° . If Se is found in the last ext., extn. is repeated as often as necessary. Expts. with mixts. containing known amts. of Se showed the method to be accurate. Te, if present, will be estd. as Se. To det. Te use the method of Browning and Flint (cf. C. A. 3, 2919).

E. W. BOUGHTON.

Determination of carbon dioxide in carbonates decomposed by solutions of ammonium chloride. A. CAVAZZI. Bologna. *Ann. chim. applicata* 4, 137-44(1915).—The method is based on the fact that small amts. of finely powdered carbonates of Ca, Ba, Sr, Mg, Zn, Pb, Cd, Bi, Cu, Li, Na, K and probably of other metals, when brought into contact with a boiling soln. of NH_4Cl , are slowly decompd. and dissolved, the carbonate changing into sol. chloride and the CO_2 evolving as $(NH_4)_2CO_3$. In this method the presence of organic substances in the carbonates is of no importance, and the rather serious inconveniences involved by certain impurities as H_2S , SO_3 , etc., in other methods, are here avoided. A soln. of $CaCl_2$ in NH_4OH is used to absorb the vapors of $(NH_4)_2CO_3$, on account of the less solubility of $CaCO_3$ than of $BaCO_3$. The prepn. of solns. and the app. employed are similar to those previously indicated (C. A. 9, 3310). The generator, however, has a capacity of 150-200 cc., and receives the carbonate in question and the NH_4Cl soln. In the collector there is always placed 40 cc. of the ammoniacal soln. of $CaCl_2$, contg. 1.66 g. $CaCl_2$. In testing some carbonates and special mixtures contg. carbonates which react in the warm with NH_4Cl and give a rapid and abundant evolution of ammoniacal vapors, the descending tube should be 60-5 cm. long and be provided with a stopcock. It is important that the samples should be finely powdered in an agate mortar, this applying also to carbonates obtained by chem. pptn. In testing argillaceous limestones 1 g. samples are taken, or when the clay is in excess, 1.5 g. The operation should take about 1.5 hrs. In this method the insol. residue contains, besides all the SiO_2 , Al_2O_3 and Fe_2O_3 , also a large part or all of the CaO and MgO that occur as silicates, and more rarely as phosphates, in marly clays. In testing cements, 4 g. material should be taken, and must be very finely powdered. Presence of sulfides, sulfites and hyposulfites does not interfere with the accuracy of the detn. In testing fat and hydraulic limes, the boiling should be continued for $1\frac{1}{4}$ hrs. Gypsum should be taken in samples of 10 g., or if contg. much $CaCO_3$ or $MgCO_3$, 5 g. or less are sufficient. Confirmatory tests were made on carbonates of arable soil, of ashes, alk. carbonates, on white lead, Bi carbonate, malachite, azurite and siderite.

S. LÉVY.

A modified method for determining carbon-free ash in plant substances. G. E. BOLTZ. *J. Ind. Eng. Chem.* 7, 859-60(1915).—Ignite 2-10 g. in a Pt dish over a low flame until most of the C is burnt off. Cool, cover with a watch glass and add 20 cc. hot H_2O . Filter into a tared 200 cc. Erlenmeyer flask, wash 3 or 4 times with hot H_2O , replace filter and contents in dish, and dry and ignite. Transfer remaining ash to the Erlenmeyer flask with hot H_2O and a policeman. Evap., dry at 110° and weigh. This wt. represents crude ash. Connect flask with app. for detg. CO_2 (cf. C. A. 7, 1994), add dil. HCl and det. CO_2 . Unburned C, sand and SiO_2 are detd. by the method

given in *Bull.* 107, U. S. Bur. of Chemistry. The CO_2 plus unburned C and sand is subtracted from the wt. of the crude ash. The remainder represents the amt. of C-free ash.

E. W. BOUGHTON.

A new reaction of isothiocyanates. G. DENIGÈS. *Bull. soc. chim.* 17, 380-1 (1915).—The alkali isothiocyanates give with Hg^{++} salts a cryst. ppt. of $\text{Hg}(\text{NCS})_2$, which seps. from 1% solns. The reaction is slow, not extremely sensitive, and is far from being characteristic. A better qual. test is that depending upon the formation of dithiotrimercuric salts according to the equation: $2\text{MNCS} + 3\text{HgSO}_4 + 4\text{H}_2\text{O} = \text{S}_2\text{Hg}_3\text{SO}_4 + 2\text{CO}_2 + 2\text{NH}_3 + 2\text{MHSO}_4$. To the soln. to be tested add 1-2 times its vol. of HgSO_4 soln., shake, filter if necessary (presence of alk. earths), and heat slowly to boiling. In presence of CNS^- a ppt. appears which under the microscope shows regularly radiating groups of prisms. Sensitivity, 0.25 g. HCNS per l. H. L. OLIN.

Rapid method for detecting mineral poisons in water. E. FLEURY. *J. pharm. chim.* 12, 215-20 (1915).—With a few test tubes and 4 reagents (HCl , Na_2S , SrSO_4 , and alk. Na-picrate paper, Grignard's reagent for HCN), a scheme of detection of As, Sb, Hg, Cu, Pb, Sn, Zn, Al, Ba, cyanides and nitroprussides in H_2O is given. In the case of cyanides, the moistened paper suspended over the liquid from which HCN is set free by boiling with 2 drops of HCl , turns a deep mahogany color. S. W.

The detection of methyl alcohol in ethyl alcohol. UMBERTO PAZIENTI. *Univ. Padua. Atti reale ist. Veneto, sci. lettere ed arti.* 74, 553-5 (1915); see *C. A.* 9, 2206.

E. J. WITZEMANN.

Simple method of obtaining melting points of fats, etc. A. W. KNAPP. *J. Soc. Chem. Ind.* 34, 1121-2 (1915).—The substance is placed on the bulb of the thermometer. The thermometer is inserted in a stoppered test tube, which acts as an air bath, and the test tube is placed in a beaker of water or glycerol. The liquid should be boiled and cooled to prevent the formation of bubbles on the side of the beaker. *For fats, waxes or fatty acids:* Very fine scrapings taken with the point of a knife are transferred with as little injury as possible to the bulb of the thermometer. They should cover less than $\frac{1}{2}$ of the bulb. Under these conditions one can plainly see when the sharp outline of the scrapings begins to soften, and also when the fat is completely transparent. *For cryst. organic substances:* If the bulb of the thermometer be pushed into a powdered organic substance some of the powder adheres. A very faint film, or a few crystals, is all that is necessary. The powder reflects irregularly the light coming from the mirror surface of the bulb, and the point at which the substance becomes liquid is plainly seen. A cryst. substance which does not adhere should be powdered.

8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR, T. WHERRY.

A crystallographic investigation of several minerals from the Pfälz. H. STRINMETZ AND B. GOSSNER. Munich. *Z. Kryst. Min.* 55, 156-61 (1915).—The region is characterized by the association of the Hg minerals cinnabar, amalgam, and calomel, with barite. Crystallographic measurements of all 4 minerals are given. A. W.

Decomposition of smaltite and löllingite by atmospheric oxidation. A. BEUTEL AND F. LORENZ. Breslau. *Centr. Min. Geol.* 1915, 359-73.—Forty-three dependable analyses of smaltite ("Speiskobalt") heretofore published, and 3 new ones by L., are tabulated, and the ratio of Co:As found to vary from 1:3.30 to 1:1.32. So-called skutterudite ("Tesseralkies") shows similar relations, the ratio of Co:As in 11 analyses varying from 1:3.14 to 1:2.65. The latter mineral thus shows no sharp distinction from the former, and the two are to be regarded as the same species. Previous attempts to det. the cause of this variability have been unsuccessful. Expts. were made on carefully analyzed material from Riechelsdorf, of which 3 specimens showed the ratios Co:As = 1:2.85, 1:2.87, and 1:2.53. Heating in a vacuum to 410° showed the absence of free As, but after long heating at 510° the product had the compn. CoAs, although in the heating curve no breaks occurred at points corresponding to any intermediate compds. such as CoAs₂ or Co₂As. On covering the mineral powder with dil. HCl and exposing to the air, the dissolved material had at first the ratio Co:As = 1:2.5, ultimately 1:3, while the residue had 1:2. It is concluded that natural smaltite contains both CoAs₂ and CoAs, but that the existence of Co₂As₃ is not certain. In like manner löllingite was studied, and from 29 analyses the ratios found to vary from Fe:As = 1:2.08 to 1:1.32 if the S is regarded as present as FeAsS, or from 1:2.38 to 1:1.32 as FeS, the former being the more probable. The oxidation expts. proved the existence of both Fe₂As₃ and FeAs₂ in natural löllingite. E. T. W.

Remarks on the chemical constitution of certain minerals. F. ZAMBONINI. Z. *Kryst. Min.* 55, 132-55 (1915).—*The nepheline group*: Z. does not agree with Thugutt (C. A. 8, 3170) that the nephelines heretofore analyzed have consisted of a mixt. of a primary mineral with decompn. products. Most clear nepheline does not agree with Thugutt's formula, and the relation Na:K does not have to be constant. Z. concludes that the group consists of combinations of Na₂Al₂Si₂O₈, K₂Al₂Si₂O₈, CaAl₂Si₂O₈, Na₂SiO₃, and NaAlO₂ (this latter mol. has not as yet been observed in nepheline itself), and that the excess Si and excess Al are to be disposed of as Al₂O₃ and Al₂SiO₅. In the cancrinite sub-group Cl, SO₃ and CO₂ play a part in the constitution of the above named mols. *Augite*: Z. discusses at length the work relating to the chem. constitution of augite and agrees in most respects with Boeke (C. A. 9, 2045; 10, 31). The relationship SiO₂:(Ca Mg Fe Mn)O = 1:1 as postulated by the modified Tschermak hypothesis, does not hold. Z. concludes that ordinary augite consists of R'SiO₃, R'R₂'O₄ and rarely small amts. of R'R₃' (SiO₃)₄, the silicate R'R₃'SiO₃ playing

no part in its constitution. *Enstatite and hypersthene*: From a study of all available analyses Z. concludes that also in the case of these minerals the Tschermak hypothesis that $\text{SiO}_2:\text{R}^*\text{O} = 1:1$ does not hold, but that they are made up of the same compds. as augite, the silicate $\text{R}^*\text{R}_2\text{SiO}_3$, playing no part in their constitution. *Babingtonite*: This mineral is entirely distinct from augite, being composed of simple metasilicates of bi- and trivalent elements. A. WANDTKE.

The geology of the Waihi Grand Junction Mine. ARTHUR JARMAN. *Bull. Inst. Mining Metallurgy* 133, 38 pp.(1915). Discussion. H. F. BAIN, J. A. L. HENDERSON, W. FRECHEVILLE, A. JAMES, G. P. ASHMORE, A. E. KITSON AND S. J. LETT. *Ibid* 134, 3-11(1915).—The ores consist of Au-bearing quartz occurring in veins in dacite beneath andesite and rhyolite, all the rocks being greatly altered (propylitized). Bell and Fraser (*New Zealand Geol. Bull.* 15(1912)) considered the productive rock to be an intrusive, cutting bedded flows of lava of the same compn. J. can discover no line of demarcation between these 2 formations and, further, finds flow structure throughout, and [apparently believing that flow structure can not occur in an intrusive] concludes that no intrusive exists, but that the rocks are all bedded flows. Dark colored partings, called carbonaceous (although analysis shows only minute amounts of C) are also cited as evidence. It is concluded that ore may be expected to continue far beyond the limits of the supposed intrusion. The discussion brings out the point that the relations are by no means as simple as concluded by J. E. T. W.

Discovery of platinum in Spain. ROBERTSON HONEY. *Commerce Reports* 290, 993(1915); *Elec. World* 66, 1393(1915).—Pt deposits have been discovered by Orueta who was appointed by the Instituto Geológico to exam. the Ronda Mountain Range for possible mineral deposits. The new Pt deposits are believed to be richer and of greater extent than those of the Ural Mountains. E. H.

9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

Washed metal. H. D. HIBBARD AND E. L. FORD. *Bull. Am. Inst. Min. Eng.* 1915, 2387-97.—The washing process consists in oxidizing out the impurities in Fe by the O of the fettling, the metal being kept at above its melting point. It was described by Holley (*Trans. Am. Inst. Min. Eng.* 8, 156(1879)) as then applied in the Krupp works. The only plant using it in this country is the Briar Hill Steel Co. of Youngstown, O. The product has a limited use in acid steel furnaces and as a carburizer in crucible steel. A plan and description of the Briar Hill plant are given. The metal is run from the blast furnace to a reservoir, where it is kept molten, and drawn off as required to the washing (Pernot) furnace which has a circular, revolving hearth. The fettling is a high-grade hematite packed so as to be practically monolithic. During the first 10 min. essentially all Si and Mn, and 75 to 80% of the P is oxidized out. In

15 min. 25 to 30% of the S is removed. At this stage, the slag is run off, and CaO added, the heat being continued to remove more P and S. Tests are taken at intervals about 5 to a heat. The test cakes when broken up show bubbles, and a faint crystalline structure. The larger the bubbles, and the fainter the crystalline appearance, the lower the P. But little C is removed. When Fe charged with C is in contact with Fe_2O_3 , both molten, formation of CO occurs at a high temp. The reaction is endothermic and the consumption of heat soon brings the temp. down to the point of stopping. This point is believed to be near 1300° . The proportion of P in the washed metal is inversely related to the amount of CO formed in a given period. As to removal of the S, the proportion in the metal bears a constant ratio to that in the slag. Curves of the elimination of Si, Mn, P and S are given. E. WALLER.

Cyanide treatment of flotation concentrate. C. BUTTERS AND J. E. CLENNELL. *Mining Sci. Press* **111**, 778-85 (1915).—Results are given of research on the application of a method of roasting, water washing and cyanide to a concentrate produced by flotation. The ore chosen (the value consisting essentially of Au) was a product of the San Sebastian mine in Salvador. The concentrates were prepd. by a modified type of the Minerals Separation flotation machine with the usual frothing agents. The results obtained indicate that the San Sebastian concentrate produced by flotation may be treated successfully by this method. The most favorable results were obtained when roasting was carried out at a low temp. Thorough washing was essential for high extn. Best results were obtained with a strength of 0.125% KCN. Assuming an extn. of 98% based on results obtained with the above method, the authors figure a net saving of \$2.26 per ton of raw ore treated. An added saving of \$0.48 in cyanide (cyanide at \$0.16 a lb. of KCN equiv.) is made, making a total saving of \$2.74 a ton or about \$9600 on a monthly output of 3500 tons. L. P. WEBBERT.

Cyanidation in Western Australia. V. F. S. LOW. *Mining Sci. Press* **111**, 819-23 (1915).—Equipment of the plant at the Corinthian North Mine is described. Oxidized ore (depth 90 ft.) is mined and treated. The sulfide ore (pyrrhotite) underlying the oxidized ore will be treated when additions to plant are completed. On entering the 20 stamp battery the ore comes into immediate contact with NaCN soln. and CaO (120 lbs. CaO to 10 tons ore under normal conditions). The crushed material is conveyed by launder to a 4 in. centrifugal pump which passes it to 2 cone separators (diam. 6 ft., depth $7\frac{1}{2}$ ft.). The overflow enters 2 thickeners, 25 ft. diam. The underflow from the cones enters 2 tube mills, the discharge of which unites with the material leaving the battery. The underflow from the 25 ft. thickeners enters 4 agitators (diam. 18 ft., depth 8 ft.) where NaCN is added to give a final strength of 0.05%. After agitation the pulp is pumped to 2 Ridgway filters; these are described in detail. The rate of wages paid in the mining and treatment departments is given. The cost of production has amounted to 63.62 c. per ton (2000 lbs.) and the treatment \$1.26 per ton, the final total cost amounting to \$2.35 per ton of ore raised and treated. L. P. W.

Metallurgy in the Coeur d'Alenes. H. A. MEGRAW. *Eng. Min. J.* **100**, 827-30 (1915).—A general description is given of the methods of milling in this district. The ores are varied and complex so that differing methods are used at nearly every mine. The fine structure and presence of blende and siderite cause serious metallurgical problems. Flotation has been of great assistance in aiding metal recovery from finely ground ores. L. W. RIGGS.

Gas-fired reverberatory furnace at Sulitjelma, Norway. C. OFFERHAUS. *Eng. Mining J.* **100**, 1033-7 (1915).—Concentrates from the Elmore vacuum oil-flotation process are roasted in an 8-hearth Wedge furnace and smelted in a gas-fired reverberatory furnace which has a regenerator for preheating the combustion air. Magnesite brick

and water-cooling pipes are used in the back part of the furnace to resist the strongly basic slag that is formed. E. J. C.

Open-hearth₁ furnace roof. ANON. *Iron Age* 95, 1284-5(1915).—In this, the Orth method of construction (cf. *C. A.* 9, 1299), the arch is built preferably of special brick shapes having a depth of 3-6 in. greater than regular roof brick. The construction is such that the roof is relieved of the function of supporting itself, and the extent to which it may be allowed to be burned away is much increased. This method of construction makes possible repairs that could not be applied₂ to the ordinary roof. L. W. RIGGS.

Apparatus for flotation separation and sulfating of ores. H. B. HOVLAND. U. S., 1,164,188, Dec. 14.

Apparatus for leaching metals from ores. B. R. KOERING. U. S., 1,163,828, Dec. 14.

Apparatus for leaching ore-pulp. B. MACDONALD. U. S., 1,163,097, Dec. 7.

Apparatus for sulfating ores. H. B. HOVLAND. U. S., 1,164,187, Dec. 14.

Apparatus for sulfating, sulfidizing and flotation of ores. H. B. HOVLAND. U. S., 1,164,189, Dec. 14.

Recovering metals from cyanide solutions. H. FORSTERLING and A. L. HALVORSEN. U. S., 1,164,636, Dec. 21. A cyanide soln., obtained, *e. g.*, from Cu, Au or Ag ore, is treated with a film of Na amalgam in a rotating drum to ppt. the metal from soln.

Apparatus for precipitating metals from cyanide solutions. B. R. KOERING. U. S., 1,163,829, Dec. 14.

Recovering zinc from an acid sulfite solution. C. S. VADNER. U. S., 1,163,286, Dec. 7. The soln. is continuously electrolyzed for the recovery of Zn and elimination of SO₂ and acid formed is partially neutralized during the process by the addition of basic Zn carbonate and lime.

Ore-roasting furnace. J. C. SIMMONS. U. S., 1,164,761, Dec. 21.

Ore-roasting furnaces. L. B. SKINNER. U. S., 1,164,130-1-2, Dec. 14.

Furnace for roasting ore. H. F. WIERUM. U. S., 1,162,894, Dec. 7.

Smelting sulfide ores. G. HAGLUND and A. GRÖNNINGSÄTER. U. S., 1,163,234, Dec. 7. The ores are continuously smelted in a converter-like furnace.

Smelting zinc ores. W. MCA. JOHNSON and E. W. HALE. U. S., 1,165,371, Dec. 21. Partly desulfurized high grade Zn ore is mixed with C and heated in fire-

clay retorts to not above 1150° to recover part of the Zn without forming slag and the residue is mixed with additional C and smelted electrically to obtain the residual Zn and other values.

Recovering iron from sulfides. L. T. WRIGHT. U. S., 1,164,049, Dec. 14. Pyrite or other Fe sulfides are heated to about 3000° to volatilize the S content and produce pure metallic Fe.

Smelting ferruginous copper sulfide ores. J. H. KLEPINGER, M. W. KREJCI and C. R. KUZELL. U. S., 1,164,653, Dec. 21. Cu sulfide ore containing Fe is sprayed into a chamber together with flux and powdered fuel and the mixt. is ignited, additional ore and flux being supplied after ignition, and air is supplied sufficient to oxidize the S and Fe and slag the Fe. The temp. is maintained sufficiently high to fuse the matte-forming Cu sulfide and slag while the particles are in suspension and raw material is added to the fused product to counteract any overoxidation. Cf. C. A. 10, 167.

Steel. A. C. DINKEY. U. S., 1,162,755, Dec. 7. High-P pig Fe is dephosphorized in a basic furnace, then mixed with undephosphorized pig Fe high in Si and the mixed metals are bessemerized in an acid converter.

Strengthening castings of steel, iron and alloys. H. E. FIELD and F. C. T. DANIELS. U. S., 1,164,487. Dec. 14. The castings are packed in old foundry sand or other inert material and heated in a furnace for at least 5 hrs. and preferably 2 or 3 days at a temp. of 675° and then allowed gradually to cool to 450° after which the supply of heat to the furnace used is shut off and the castings are allowed to cool in the closed furnace, to atm. temp.

Plating iron or steel with aluminium. F. MOENCH. U. S., 1,165,338, Dec. 21. The surface of Fe or steel is freed from oxidized matter and org. substances by successive treatment with hot HCl and with KMnO_4 and KClO_4 . The article is heated to a dull red heat and rubbed with a piece of Al previously washed with H_2O_2 and heated almost to the m. p. and the Al coating thus formed is smoothed while molten and allowed to cool slowly.

Alloy for non-rusting edged tools. P. J. A. DOUGLASS. U. S., 1,163,813, Dec. 14. Ni 67 is combined with Cu 33, ferro-Si 10 and Cr 2 parts.

Copper-alloy-coated zinc lithographic plates. F. NIEMEYER. U. S., 1,163,166-7, Dec. 7.

Hydrogen; sulfur; treating ores. W. M. HOOTON. Brit., 18,007, July 30, 1914. Metallic sulfides and sulfide ores, especially Fe pyrites, are treated with steam at 750 – 1000° , the products being porous oxides comparatively free from S and a mixt. of H, S, H_2S , and SO_2 . The H is purified, the S being sepd. during the purification. The pyrites are fed into a retort into which steam is blown. S condenses in the upper part of the retort and collects in a seal, and the gaseous products pass through a hot chamber containing bog Fe ore or porous Fe oxide obtained by the reaction to induce reaction between H_2S and SO_2 , then through a chamber in which S condenses in powder form, then through a cooler preferably containing cold bog Fe ore to remove the last traces of H_2S , and then through H_2O to remove any SO_2 . The steam may be superheated etc. To reduce the quantity of H_2S , the gases may be cooled quickly after leaving the retort.

Agglomerating iron ores. D. V. HOLLINGWORTH and R. C. MACGOWAN. Brit., 18,103, July 31, 1914. Blackband and like Fe ores are coked at a red heat with exclusion of air, and volatile constituents are recovered. The coked product contains particles of Fe oxide and C in very intimate contact, and part of the C is in chem. combination with the Fe.

Treating complex ores. C. J. INGLIS. Brit., 18,682, Aug. 14, 1914. Complex sulfide ores are chlorinated in the presence of NaCl or, if containing much Fe, are mixed with NaCl and subjected to a chlorinating roast, and the product is treated with hot H₂O to ext. sol. chlorides. A sol. iodide, such as kelp, KI, or ZnI₂, is then added to ppt. Ag, Au, and Pb iodides, which are reduced to the metallic condition by scrap Zn, thus re-forming ZnI₂ for use again. From the mother liquor, Cu is removed by electrolysis or treatment with Fe, and the ZnCl₂ remaining may be electrolyzed to regenerate the Cl and recover the Zn. The residue of the ore contains the Sn, which is recovered by washing, and the Bi and Te are rendered sol. and the soln. run off.

Cementation. SOC. ANON. ITALIANA G. ANSALDO & CO. Brit., 18,386, Aug. 7, 1914. In a process for the cementation of armor plates, in which both solid and gaseous agents are used, the plates are arranged vertically, two by two, on the hearth of a furnace so as to enclose, with two other metal plates or blocks, a space into which the solid agent is charged at the top and the gaseous agent is introduced at the bottom through pipes. The solid agent between the plates is gradually replaced as consumed from refractory receptacles. The furnace may be gas-fired and comprize one or two movable hearths.

Heat-treating steel. SOC. ANON. ITALIANA G. ANSALDO & CO. Brit., 18,387, Aug. 7, 1914. In a process of heat-treating steel articles such as gun parts and armor plates, the article is heated first to a temp. in the neighborhood of the first arrest on the cooling curve, such temp. being maintained const. during a certain interval, after which the temp. is gradually lowered to a second detd. temp. which is somewhat higher than the last arrest on the cooling curve, and is maintained const. for a shorter time than the first. The article is then cooled, and the treatment may be followed by an ordinary tempering or reheating. In specific examples, the first temp. may be 1070° or 1000°, and the second temp. 680° or 800°. Steels containing: (1) C 0.25, Mn 0.4, Si 0.1, S 0.005, P 0.008, Ni 2.56, Cr 0.55, V 0.15, W 0.78%; and (2) C 0.4, Mn 0.6, Si 0.15, S 0.009, P 0.02, Cr 2.2, and Ni 2.5%, are referred to.

Melting metals. J. E. LOWDEN. Brit., 18,429, Aug. 7, 1914. Means are provided for maintaining a const. level in the melting pot.

Furnaces. A. W. CALVERT. Brit., 18,460, Aug. 8, 1914. A gaseous fuel furnace for removing Sn, Pb, or other metallic coating from sheets, hollow metal ware and similar articles, comprizes a hopper, having inlet and outlet doors, from which the articles are fed on to two or more traveling conveyers arranged tandem-wise. Means are provided for collecting the molten metal, and the articles finally pass into a collecting chamber, from which they are discharged.

Cover for hardening vessels for ore briquets, lime sandstone. G. KRÄSTING. Ger., 285,340, May 1, 1914.

Permanent mold for casting spoke- and disk-wheels. F. ROEMER. Ger., 285,032, June 12, 1913.

CHAS. A. ROUILLER.

Isomeric hydrazones of glyoxylic acid. M. BUSCH, FRIEDR. ACHTERFELD AND RUD. SEUFERT. Univ. Erlangen. *J. prakt. Chem.* 92, 1-39(1915).—The occurrence of hydrazones of OHCCO₂H in 2 isomeric forms has previously been noted in only 2 cases, that of phenylhydrazone-*o*-nitrophenylglyoxylic acid [cf. Fehrlin, Ber. 23, 1574(1890)] and of *o*-bromophenylhydrazoneglyoxylic acid [cf. Busch and Meussdörffer, C. A. 1, 1719]. The *o*-nitrophenylhydrazoneglyoxylic acid has been previously

prepd. [cf. Elbers, *Ann.* 227, 353(1885) and B. and M., *loc. cit.*] and is described as occurring in but 1 form. B., A. and S. have now found that this hydrazone and also several other substituted hydrazones of OHCCO_2H may be isolated in 2 forms, one difficultly sol. in C_6H_6 and predominating when the reaction between $\text{Cl}_2\text{CHCO}_2\text{H}$ and the corresponding hydrazine is carried out in the presence of alkali carbonates or bicarbonates, and the other form, readily sol. in C_6H_6 , with its formation favored by the presence of caustic alkali. The former is designated as the α -form, while the latter, sol. in C_6H_6 , is called the β -form. Two types of isomerism are theoretically possible, stereoisomerism as shown in (I) and (II), or desmotropism as represented by (III) and

(IV). The authors favor (I) and (II), basing their views on the following facts: (1) Two series of salts, esters, and Bz derivs. are formed, *i. e.*, the isomerism continues in the derivs. (2) There is no marked difference in the intensity of color in the 2 forms. (3) The acids are rather stable and are not very readily converted one into the other; alc. HCl or H_2SO_4 more or less isomerizes the β -form; under certain conditions alkali will convert the α - into the β -form, but an *o*-substituent must usually also be present. Heating the free acids at the m. p. to produce isomerization is unsatisfactory, due to decompn.; when the esters are similarly treated, an equil. is established after some time, in which the β -form usually predominates. When heated in indifferent solvents, the acids are more or less easily decompd., while the esters remain unchanged and are not isomerized. (4) Ac_2O causes the β -form of the esters to rearrange, forming the same Ac compd. as the α -ester. (5) Both isomers are unattacked by Zn dust + AcOH . (6) HNO_3 reacts with both forms of the acids giving, in most cases, one and the same HON:CHN:NR ; many *o*-substituted hydrazones fail to react and only the α -forms of the esters are attacked by HNO_3 . (7) Dialkylhydrazones, $\text{R}_2\text{NN:CHCO}_2\text{H}$, occur in only one form. (8) The elec. cond. of the β -acids is about 2.5 times as great as that of the α -acids. Points 6 and 7 cannot be explained on the assumption of stereoisomerism, and these reactions will be further investigated. While a substituent in the *m*- or *p*-positions of the PhNHNH_2 has little influence on the proportions of the isomers formed, an *o*-substituent distinctly favors the formation of the β -form, to the entire exclusion of the α -form in some cases. To prep. the α - and β -forms of phenylhydrazoneglyoxylic acid, 10 g. $\text{Cl}_2\text{CHCO}_2\text{H}$ in 10 g. H_2O were treated with 17 g. KOH (4 mols.) in 30 cc. H_2O and 8 g. PhNHNH_2 in alc. added. The mixt. was then heated at 100° for 2 hrs., freed from alc., shaken out with Et_2O , freed from Et_2O and acidified with AcOH , when the acid K salt of the α -acid sepd. The free α -acid, previously described, is pptd. from aq. solns. of this salt by HCl in excess; stout brownish needles from alc., m. (not sharply) 138° , decomp. $142-3^\circ$, varying according to the rate of heating; yield, 4-5 g.; acid potassium salt and acid sodium salt, compns. indefinite; normal sodium salt, $\text{C}_6\text{H}_5\text{O}_2\text{N}_2\text{Na}$, sepg. from alk. solns., leaves from H_2O or alc., shrivels 250° , but does not m. below 300° ; ammonium salt, $\text{C}_6\text{H}_5\text{O}_2\text{N}_2$, pptd. from NH_3 soln. by AcOH , amber prisms efflorescing in the air with the evolution of NH_3 , m. 175° with effervescence; Me ester (a), needles or leaves from alc., m. $136-7^\circ$ [cf. Harries, *Ber.* 36, 1936 (1903)]; acetyl derivative of (a), formed when (a) is heated with Ac_2O + fused AcONa at 100° for 1 hr., needles from dild. alc., m. 105° . Two mols. of (a) condense in the presence of very concd. alc. HCl to form ethyl benzeneazoacetylphenylhydrazoneglyoxylate, $\text{PhN}(\text{COCH}_2\text{N:NPh})\text{N:CHCO}_2\text{Et}$, orange-red needles from alc., m. 154° , which is decolorized by Zn + AcOH ; yield, 70%; the free acid, obtained on gentle warming with dild. KOH , orange-yellow needles from abs. alc., m. 225° with effervescence. β -

Phenylhydrazonегlyoxylic acid is pptd. by HCl in excess from the AcOH soln. remaining after the pptn. of the acid K salt of the α -form. It is sepd. from a small amt. of the α -form by extg. with C_6H_6 , from which the β -form seps. in clusters of yellow needles on concg. or dilg. with petr. ether; yield, 2.0 g.; yellow needles from alc., shriveling 125° and m. $128-9^\circ$ (decompn.); *ammonium salt*; *sodium salt*, yellow leaves, shrivels 230° and m. indefinitely at about 273° (decompn.); *methyl ester* (b), from the Ag salt and MeI or the free acid and Me_2SO_4 , yellow crystals from petr. ether, m. 70° (not sharply); the α -ester partially rearranges to the β -form on heating at $145-50^\circ$, but when the β -acid is treated with $MeOH + H_2SO_4$, it rearranges largely to the α -form with accompanying esterification. Thus, while the esters of the α -forms were best obtained by esterification in the presence of H_2SO_4 , the esters of the β -acids had to be prepd. by another method—the Me esters by shaking at room temp. with an excess of Me_2SO_4 and Na_2CO_3 . (b) + Ac_2O gives the Ac deriv. of (a). The phenylazoformaldoxime obtained by the action of HNO_3 on the β -acid is identical with that prepd. from the α -form (cf. B. and M.). The following glyoxylic acid hydrazones were prepd. and sepd. in a similar manner. *asym. m-Xylylhydrazonегlyoxylic acid*; α -form, yellow leaves, m. $125-6^\circ$ with effervescence; *sodium salt*, yellow leaves; β -form, obtained almost exclusively in the presence of an excess of alkali, yellow needles, m. 110° with effervescence; *sodium salt*, yellow leaves; *methyl ester* (c), needles from alc., m. 69° . The β -acid on standing at room temp. 4 hrs. in 10 parts $MeOH + 1$ part H_2SO_4 gave 20% α -acid, 40% *methyl ester of α -acid* (d), light yellow needles from alc., m. $142-3^\circ$, and 30% unaltered material. Both esters are unattacked by $Zn + AcOH$ at $60-70^\circ$; on heating at $150-60^\circ$ each is partially converted into the isomeric form; on standing for 24 hrs. at room temp. with $MeOH + H_2SO_4$, 15% of (d) is converted into (c) and, starting with (c), 50% of (c) is converted into (d); if (c) is allowed to stand 4 days with $MeOH + H_2SO_4$, 67% is isomerized. Both esters give the α -acetyl derivative, prisms from dild. alc., m. 88° , when treated with Ac_2O and $AcONa$. *vic-m-Xylylhydrazonегlyoxylic acid*; α -form, light yellow cubical prisms, m. $142-4^\circ$ with effervescence; β -form, S-yellow needles, m. $115-7^\circ$ (decompn.); in $MeOH + H_2SO_4(10:1)$ at room temp. for 5 hrs., 50% was converted into the α -form. *ps-Cumylhydrazonегlyoxylic acid*; α -form, obtained in small amt. in the presence of K_2CO_3 , yellow leaves from alc. on adding C_6H_6 , m. $144-5^\circ$; the β -form, which predominates in this case and is rather difficultly sol. in C_6H_6 , greenish yellow needles from alc., m. 127° with effervescence; *methyl ester* (e), deep yellow columnar prisms from alc., m. 86° ; the *methyl ester of the α -acid* (f) was obtained, mixed with (e), when the β -acid was treated with $MeOH + H_2SO_4$, bright yellow needles, m. 175° ; heated at 175° , (f) is chiefly converted into (e); the reverse change does not occur. Only the β -form of *o*-anisylhydrazonегlyoxylic acid is formed in either KOH , K_2CO_3 , or $NaHCO_3$ solns. (cf. B. and M., *loc. cit.*). *o*-Chlorophenylhydrazonегlyoxylic acid; α -form, blunt yellow needles, m. $153-4^\circ$ with effervescence; β -form, previously prepd. by B. and M., m. $142-3^\circ$. The β -form of *o*-bromophenylhydrazonегlyoxylic acid (cf. B. and M.) is formed exclusively in the presence of KOH ; 33% of the α -form is obtained when K_2CO_3 is used. The conversion of the β - into the α -form in the presence of $MeOH + H_2SO_4$ is very slow, 4 days being required to convert 80% into the α -ester, needles from dild. alc., m. 139° ; 20% alc. KOH at room temp. will convert the α -acid into the β -form. *m*-Bromophenylhydrazonегlyoxylic acid; α -form, yellow needles from dild. alc., m. $136-9^\circ$ (not sharply); β -form, bright yellow needles, m. 122° . *p*-Bromophenylhydrazonегlyoxylic acid; α -form, bright yellow needles, m. $130-7^\circ$ (decompn.); *benzoyl derivative*, $BrC_6H_4NH:N:CHCO_2Bz$, obtained in C_6H_5N with $BzCl$, bright yellow leaves from dild. alc., m. $175-6^\circ$; *methyl ester*, needles from alc. or C_6H_6 , m. $191-2^\circ$; β -acid, bright yellow leaves from C_6H_6 , m. 121° with effervescence; *benzoyl derivative*, bright yellow leaves or needles, m. 123° ; *methyl ester*, leaves from dild. alc.

m. 102°. The β -form of *o*-iodophenylhydrazonoglyoxylic acid (cf. B. and M.) could not be rearranged to form a β -form; this constitutes the only case in which a β -acid could not be isomerized. *p*-Iodophenylhydrazonoglyoxylic acid; α -form, orange-yellow needles, m. 155° (decompn.); β -form, straw-colored needles, m. 135° with effervescence (not sharply). The yields of both forms were small. Methylphenylhydrazonoglyoxylic acid seps. in only 1 form, probably the β -form (g), leaves from alc., m. 165–7° (decompn.); methyl ester (h), light yellow prisms or plates from alc., m. 61–2°. A 2nd form of ethylphenylhydrazonoglyoxylic acid could likewise not be isolated (cf. Elbers, *loc. cit.*) nor could a 2nd form of semicarbazonoglyoxylic acid or phenylhydrazonopyruvic acid (i) be prep'd. (cf. Darapsky and Prabhakar, *C. A.* 7, 347). (a) in alc. with HNO_3 gave methyl benzeneazoformaldoximecarboxylate, $\text{PhN:NC(:NOH)CO}_2\text{Me}$, red crystals from dild. alc., m. 136°; in concd. HCl it produces a blue-violet coloration. Under similar conditions (d) is converted into an oxime, red crystals from alc., m. 132°; the soln. in concd. HCl is dark blue; (c) did not give a similar oxime. Oxime of (f), pointed crystals, m. 170°; (e), (g) and (h) were not appreciably attacked by HNO_3 ; (i) was converted into PhN:NCMe:NOH with the elimination of CO_2 [cf. Bamberger and Grob, *Ber.* 35, 70(1902)]. The hydrazone acids and salts will not add PhCNO ; the ester (a) heated with PhCNO at 120° is converted into methyl diphenylsemicarbazonoglyoxylate, $\text{PhNHCONPhN:CHCO}_2\text{Me}$, needles, m. 159°, which is sapond. by dild. alc. KOH on gentle heating, giving diphenylsemicarbazonoglyoxylic acid, needles from alc., m. 191° with effervescence and blackening. (d), (c) and (f) do not add PhCNO , while (e) gives a small yield of semicarbazone at 170–80°, needles, m. 215–6°. When Cl-CHCONHPh in $\text{C}_6\text{H}_5\text{N}$ was heated with PhNHNH_2 and K_2CO_3 for several hrs. and then allowed to stand exposed to the air, formazylhydride, PhNHN:CHN:NPh was obtained; this was also produced when phenylhydrazonoglyoxylic acid was treated with PhNHNH_2 .

NORMAN A. SHEPARD.

Preparation of glycoll and diethyl carbonate. W. A. DRUSHEL AND D. R. KNAPP. *Am. Jour. Sci.* 40, 509–10(1915).—About 700 cc. NH_4OH satd. with NH_3 at 0° was slowly treated with 100 g. $\text{CH}_2\text{ClCO}_2\text{H}$ in the least possible amt. of H_2O and allowed to stand for 5 days. The glycoll was recovered from the mixt. by the Cu(OH)_2 method but in no case was the yield over 55% of the acid used so this is no improvement over Kraut's method of working at 10°. Et_2CO_3 was made by treating powdered KCN covered with abs. alc. with 1 equiv. of ClCO_2Et in an equal vol. of abs. alc. and boiling on the H_2O bath for 1 hr. to complete the reaction. The residue was filtered off and the filtrate fractionally distd. Re-distn. gave Et_2CO_3 , b. 127°, in 50% yield of the ClCO_2Et used.

R. L. SIBLEY.

Preparation and properties of hydracrylic esters. W. A. DRUSHEL AND W. H. T. HOLDEN. *Am. J. Sci.* 40, 511–4(1915); cf. *C. A.* 9, 615.—Hydracrylic acid was prep'd. by adding to the Na salt in the least possible amt. of H_2O a little less than the theoretical amt. of H_2SO_4 (1:1) and keeping the mixt. cold. The H_2O was then evap'd. off and the acid extd. from the residue by the alc. used in the subsequent esterification process. The alc. soln. of the acid was treated with an excess of pure anhydrous CuSO_4 and boiled under a reflux condenser on a sand bath until 80–90% of the acid had been esterified, which was detd. by titration against 0.1 N Ba(OH)_2 . At the end of the reaction the CuSO_4 was filtered off, the unchanged acid neutralized with Na_2CO_3 , the excess of alc. distd. off and the ester distd. under 12–20 mm. The esters so prep'd. were: methyl, b_{12} 79°, d_4^{25} 1.118, n_D^{23} 1.4306; ethyl, b_{12} 84°, d_4^{25} 1.064, n_D^{23} 1.4271; propyl, b_{12} 98°, d_4^{25} 1.043, n_D^{23} 1.4341; isopropyl, b_{12} 95°, d_4^{25} 1.071, n_D^{23} 1.4303; isobutyl, b_{12} 104°, d_4^{25} 1.013, n_D^{23} 1.4342; isoamyl, b_{12} 121.5°, d_4^{25} 0.988, n_D^{23} 1.4374. R. L. SIBLEY.

Electrochemical synthesis of phenylhydroxylamine. F. M. FREDERIKSEN. Cornell Univ. *J. Phys. Chem.* 19, 696–701(1915).—F. obtained PhNHOH in 30–40%

yield by Wohl's method (*Ber.* 27, 1432(1894)) by heating PhNO_2 with CaCl_2 and Zn dust in alc. He then duplicated the reaction electrolytically with Zn electrodes in NH_4Cl . A diaphragm was not needed so that the current was not cut down. The alc. soln. was stirred during electrolysis. After reduction had proceeded to the desired point, the soln. was filtered by suction and the alc. distd. off. The soln. was then satd. with NaCl and extd. with Et_2O ; the Et_2O was removed and the residue crystd. from C_6H_6 containing a little ligroin to render the PhNHOH less sol. Five different expts. are reported in which the amts. of NH_4Cl , of PhNO_2 , the temp., the time of reduction and the current were varied and yields of 21–9% resulted. R. L. SIBLEY.

Some derivatives of anemonin. YASUHIKO ASAHINA. *J. Pharm. Soc. Japan* 403, 1041(1915).—By the prepn. of the tetra-Br addition compd., $\text{C}_{10}\text{H}_8\text{O}_4\text{Br}_4$, m. 175° , and of the dihydrobromide, $\text{C}_{10}\text{H}_8\text{O}_4\cdot 2\text{HBr}$, m. 182° , the work of Beckurts (*Arch. Pharm.* 230, 205(1892)), and that of A. (*C. A.* 8, 1780) are confirmed. Anemoninic acid was obtained in cryst. form by digesting anemonin with aq. KOH , acidifying the deep brown soln. with HCl , and extg. with AcOEt . The crystals, $\text{C}_{10}\text{H}_{10}\text{O}_7$ (from petr. ether) m. $116\text{--}7^\circ$, are very hygroscopic, sol. in H_2O and alc. A 2nd anemoninic acid, designated α -anemoninic acid, and its sodium, potassium and lead salts were prepd.; the Na salt by digesting anemonin with alc. NaOH in abs. alc.; on cooling the yellowish brown crystals sep. out; the Pb salt by treating the Na salt with $\text{Pb}(\text{OAc})_2$, discarding the brown ppt. first formed and retaining the white ppt. which sepd. out on standing. The acid was obtained by decomp. the Pb salt with dil. H_2SO_4 and extg. with Et_2O . The white, needle-like crystals, from Et_2O , m. 120° and were sol. in H_2O and alc. By boiling in dil. HCl , it was converted into the other anemoninic acid (m. p. 210°) which A. termed the β -acid, and which had been previously prepd. by Beckurts, who treated anemonin with H_2O and PbO , and by Meyer (*Monatsh.* 17, 283), who hydrolyzed dimethylanemonin with dil. HCl . The semicarbazones are white in color, that of the α -acid m. 220° , that of the β -acid at 270° . The phenylhydrazone of the α -acid is brown while that of the β -acid is carmine. Both change color at about 220° and decomp. around $235\text{--}40^\circ$. In the catalytic reduction of anemoninic acid and that of dimethylanemonin 2 mols. H_2 were absorbed. The phenylhydrazone of the compd. formed m. 170° . In the catalytic reduction of anemoninic acid 1 mol. H_2 was absorbed. The product of the last reduction was found to be identical with anemoninic acid, $\text{C}_{10}\text{H}_{10}\text{O}_6$, prepd. according to M.'s method (reduction of anemonin with Zn and HCl). A. concludes that anemoninic acid is not a simple anhydride of anemoninic acid because of its different behavior toward alkalis. The latter when treated with the equiv. amt. of KOH becomes yellow, but when an excess is added, a red-brown soln. results. The yellow color is assumed to be due to the K salt of the acid and the red-brown color to an anhydride which forms a colored enol salt with alkalis. A. attempts to explain the reactions involved in the hydrolysis of anemonin to anemoninic acid. The structural formulas of the last named compds. are given. An abstract in German precedes the article. E. W. DAUDT.

Chromoisomeric salts and chromo esters from *p*-nitrobenzyl cyanide. J. LIPSCHITZ AND F. W. JENNER. Univ. Zurich. *Ber.* 48, 1730–40(1915).—When 2 g. $p\text{-O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{CN}$ (a) in just enough boiling abs. alc. is shaken vigorously with the calcd. amt. of NaOEt or KOEt , quickly cooled, treated with dry Et_2O , quickly filtered on a covered funnel and dried *in vacuo* over KOH and H_2SO_4 , the sodium and potassium salts are obtained as almost black cryst. powders; attempts to obtain the Rb salt with alc. RbOH gave products always containing too little Rb (33.61% instead of 34.68%). When freshly prepd., the salts dissolve in alcs. with intense KMnO_4 -red color; on standing (the Na salt about 3 hrs., the K salt 24 hrs.), the solns. change color, finally becoming a pure emerald-green; the solid salts likewise slowly change into the green form on

standing (the Na salt most rapidly (8-14 days), while the Rb salt after 9 months had changed only superficially); the same change is effected more rapidly at high temps. (after 5-6 hrs. at 105° in the case of the Na salt and 10 hrs. at $130-3^{\circ}$ in the case of the K salt, while the Rb salt is unchanged after days at 135°); at higher temps., there is sudden, complete decompn. with evolution of gas and formation of a black residue insol. in org. solvents. There is no change in wt. in the transformation and the resulting green salts have the same compn. as the original red ones; the red and the green Na salts show the same mol. wt. (119.9 and 123.7, resp.) in boiling MeOH. The green solns. turn KMnO_4 -red with alcoholates and conversely the red become green with (a) or CO_2 . Acid green salts could not be obtained with 2 mols. (a) and 1 mol. alcoholate, the red neutral salts being always formed. Other alkali salts could not be obtained pure; the impure green Ag salt (8 g.), however, in the necessary amt. of Me_2CO , shaken 12 hrs. with 40 g. MeI, filtered, evapd. *in vacuo* and recrystd. from Me_2CO , yields the *dimethyl ester*, $\text{MeO}_2\text{N}:\text{C}_6\text{H}_4:\text{C}:\text{NMe}.\text{Me}_2\text{CO}$, emerald-green leaflets, smells of isonitrile even at room temp., sol. in org. solvents with green color changed by KOH to deep blue; 4 hrs. boiling with alc. KOH produces evolution of carbilamine and a gradual change in color to dark brown or black; on cooling there seps. a black-brown, ill-defined K salt giving with HCl a yellow-brown flocculent acid; boiling of the ester with HCl gives as the final product a very small amt. of a brown substance m. about 210° , sol. in alkalies with violet to blue-red color, possibly $[(\text{O}_2\text{NC}_6\text{H}_4)(\text{O}_2\text{NC}_6\text{H}_4\text{CO})\text{CH}]_2\text{C}-(\text{CH}_2\text{C}_6\text{H}_4\text{NO}_2)\text{NHMe}.\text{HCl}$ (found: 56.09% C, 4.14% H), resulting from the condensation of $\text{O}_2\text{NC}_6\text{H}_4\text{COCH}_2\text{C}_6\text{H}_4\text{NO}_2$, first formed as chief product, with the half sapon. ester $\text{O}_2\text{NC}_6\text{H}_4\text{CH}:\text{C}:\text{NMe}$. When 5 g. of the Na salt in 150-200 cc. MeOH is boiled 3 hrs. at most with 25 g. MeI under a reflux condenser, quickly freed from MeOH and MeI in a wide dish on the H_2O bath, dried *in vacuo*, warmed to 40° in small amts. with H_2O , cooled with ice-NaCl as soon as the ester melts and floats on the NaI soln. and quickly filtered as soon as it solidifies again, dissolved in dry Et_2O (this leaves an insol. dark green substance with 9.09% N), and quickly evapd. *in vacuo* over KOH and H_2SO_4 there is obtained the *monomethyl ester*, $\text{MeO}_2\text{N}:\text{C}_6\text{H}_4:\text{CHCN}$, in green cryst. aggregates m. below 40° ; when fresh, it dissolves in org. solvents with emerald-green color at once changed to KMnO_4 -red by alkalies and to yellow-brown, with regeneration of (a), by HCl. In a vacuum desiccator it is stable about 48 hrs.; in the air and slowly *in vacuo* it rearranges into a light yellow substance much less sol. in Et_2O , which is also the sole product when the prepn. of the green ester is not carried out with sufficient rapidity; the yellow product is 3,4-Me(O_2N) $\text{C}_6\text{H}_3\text{CH}_2\text{CN}$, m. 63° after alternate recrystns. from alc. and H_2O (Barger and Ewins, *C. A.* 5, 1083, give 52°); with KMnO_4 in boiling alkali it gives the acid, m. about 220° . The spectra of the green and red salts are identical in the ultraviolet and in the visible region are at least analogous, the bands of the green salt and ester being merely shifted further towards the shorter wave lengths, whereas the spectra of quinone and quinol differ considerably. Therefore, if the spectrum of the red salt is considered as quinoid (cf. Hewitt, *C. A.* 7, 564), so must also that of the green salt, and the difference between the salts is not to be assigned to structural isomerism. As a secondary valence relation to the CN group would involve a 7- or 8-membered ring and is quite improbable, L. and J. tentatively propose the formulas below for the 2 salts.

CHAS. A. ROULLER.

Organic antimony compounds. I. Action of antimony trichloride on triphenyl-antimony. GERHARD GRÜTTNER AND MAXIMILIAN WIERNIK. Charlottenburg. *Ber.* 48, 1749-59(1915); cf. *C. A.* 9, 3247.—The results reported by various investigators of the action of SbCl_3 on SbPh_3 differ so greatly that their work has been repeated. In working up the product (from 30 g. SbPh_3 , 40 g. SbCl_3 and 18 cc. xylidine) by Hasenbäumer's method (*Ber.* 31, 2910(1898)), the amt. of SbCl_3 removed by shaking with HCl is, contrary to his statement, considerable, and since very nearly the amt. calcd. for the formation of PhSbCl_2 was used and only very little Ph_3Sb was detected after the reaction, the latter does not proceed exclusively according to H.'s equation: $\text{Ph}_3\text{Sb} + 2\text{SbCl}_3 = 3\text{PhSbCl}_2$. To be sure, analysis of the distillate b. $270-300^\circ$ give values agreeing, within the exptl. errors, with those calcd. for PhSbCl_2 (C 26.39%, H 1.95%, Sb 44.65%, Cl 26.17%), but if it is shaken with 2 vols. of 15% HCl , the Cl content of the residue decreases considerably (17.60%; calcd. for an equimol. mixt. of PhSbCl_2 and Ph_3SbCl 18.44%). Working up the product by Michaelis' method (*C. A.* 5, 3810) gave a distillate b. $180-220^\circ$ with 23.8% Cl falling, after shaking with 15% HCl and removing the HCl *in vacuo* over P_2O_5 and KOH , to 19.22%; repeated shaking with cold 15% HCl , which easily and completely removes admixed SbCl_3 , produced only a very slight further lowering of the Cl content, and the excess over that calcd. for Ph_3SbCl (11.47%) is due to PhSbCl_2 , which is insol. in cold 15% but quite sol. in hot 20% HCl . A portion of the distillate which had been shaken with cold 15% HCl and contained 19.22% Cl was heated 4 hrs. in CO_2 at $200-10^\circ$, again shaken with 2-3 vols. of cold 15% HCl and freed from HCl over P_2O_5 and KOH ; it then contained 13.1% Cl, completely solidified after a time and after repeated rubbing up with petr. ether showed the m. p. 68° of M.'s Ph_3SbCl . May's (*C. A.* 7, 70) and Morgan's (*C. A.* 6, 1153) modifications of the method produced no material changes in the compn. of the distillate. These results show that the crude product changes in compn. in every method of purification involving distn., so that the true course of the reaction cannot be detd. in this way, although the splitting off of SbCl_3 which always occurs makes it probable that the decompn. proceeds according to the equation $2\text{PhSbCl}_2 = \text{Ph}_3\text{SbCl} + \text{SbCl}_3$, but as no other means than distn. is known for the sepn. of the constituents the extent of this dissociation cannot be detd. The conversion of the chlorides into the corresponding oxides or acids also does not offer a means of sepn., as these compds. occur in differently hydrated forms of varying solubility; indirect analysis, likewise, offers no clue to the constitution of the reaction products, as the number of their constituents is not known. The conversion of the chlorides into their alkyl derivs. by means of the Grignard reagent, however, affords a method of considerable accuracy, as the reaction proceeds smoothly, the resulting compds. can be distd. *in vacuo* in CO_2 without decompn. and there is never a replacement of the Ph groups by the entering alkyls. The use of MeMgBr and EtMgBr gave the same results; only those obtained with EtMgBr are reported. Two portions each of 150 g. Ph_3Sb , 195 g. SbCl_3 and 90 cc. xylene were heated in sealed tubes 40 hrs. at $240-5^\circ$, the combined products extd. twice with 2-3 vols. of cold 15% HCl , filtered, dried with CaCl_2 , freed from xylene under 16-8 mm. (temp. of the bath not above 80°) and 35 g. of the viscous residue treated with EtMgBr (Expt. 1), while the remainder was distd. in CO_2 under 16-8 mm. up to 280° (bath temp.) at the rate of 3 drops every 2 sec.; 25 g. of this distillate were treated as above with HCl and then with EtMgBr (Expt. 2), while the remainder was again distd. as above and 25 g. of the new distillate again treated with HCl and then with EtMgBr (Expt. 3). The 3 distillates in 5 vols. Et_2O and the Mg compd. from about equal wts. of EtBr were boiled 0.5 hr., decompd. with H_2O , the Et_2O layers removed in CO_2 (air being carefully excluded), freed from Et_2O by distn. over CaCl_2 in CO_2 at atm. pressure, filtered and fractionated under 16-8 mm. in CO_2 . The following vols. of the various fractions were obtained in Expts. 1, 2 and 3, resp.: $125-52^\circ$,

6.2, 3.7, 2.0; 152–75°, 3.0, 1.9, 1.8; 175–205°, 2.9, 7.4, 9.1; 205–225°, 2.9, 2.0, 2.0 cc. The 125–52° fraction contains about 95%; the 152–75° fraction about 50% of EtSbPh (see following abstr.); the other 50% of the latter fraction and all of the 175–205° fraction consist of EtSbPh₃, while the 205–225° fraction contains 50% of EtSbPh₃ and 50% of a higher boiling substance not certainly identified as SbPh₃. The relative % of PhSbCl₂ and Ph₂SbCl in the 3 expts. were therefore 57, 43; 34, 66; 21, 79, resp. In other words, PhSbCl₂ decomps. at its b. p. *in vacuo* into Ph₂SbCl and SbCl₃, and the lack of agreement in the literature is due to the different lengths of time the various workers distd. their products. Under conditions otherwise the same, a 50% increase of the amt. of SbCl₃ does not materially change the relative amts. of the 2 chlorides (58, 42%), while an increase in the temp. to 250–5° and of the length of the heating to 75 hrs. increases the amt. of the PhSbCl₂ (68 and 70%, resp.). II. Preparation of mixed alkylarylstibines. *Ibid* 1759–64.—*Dimethylphenylstibine*, prepd. as indicated above (yield, 5–6 g. from 25 g. of the crude product of the reaction between SbPh₃ and SbCl₃), b₁₈, 112°, fumes slightly in the air, quickly oxidizes, especially in soln., mol. wt. in freezing C₆H₆, 228, d₄²⁰ 1.4490, n_D^{19.5} 1.5983, n_F–n_C^{19.5} 0.02523. Boiled a short time with excess of MeI it quant. yields the *methiodide*, needles from alc.-Et₂O, evolves I about 235°, sublimes at a slightly higher temp. *Ethiodide*, prepd. by heating the Me₂SbPh 5 hrs. at 100° with excess of EtI, evolves I about 150°, sublimes 225°. *Chloride*, C₆H₅SbCl₂, obtained almost quant. by passing Cl 0.5 hr. into the Me₂SbPh in 10 parts CCl₄, evapg. at room temp. and crystg. from AcOH, m. 128°. *Bromide*, m. 112–3°. *Iodide*, from the Me₂SbPh and somewhat less I than is necessary to produce a color in petr. ether, cryst. powder, m. 98.5–9.0°; excess of I gives dark products richer in I and crystg. poorly. *Diethylphenylstibine*, in 6–6.5 g. yield from 25 g. crude chlorides, b₁₈, 128°, mol. wt. in C₆H₆, 250°, d₄²⁴ 1.3487, n_D^{21.8} 1.5903, n_F–n_C^{21.8} 0.02373, fumes strongly in the air, oxidizes with vigorous evolution of heat and, when finely divided (on filter paper), occasionally ignites. *Methiodide*, obtained quant. by heating the components 2 hrs. at 100°, needles from alc., loses I above 225° and then sublimes. EtI is not added after 5 hrs. at 100°. *Chloride* and *bromide*, oils which cannot be distd. without decompn. *Iodide*, pale yellow, hexagonal leaflets from C₆H₆, long prisms from Et₂O, m. 88.5–9.0°. *Methyldiphenylstibine*, obtained in 10–1 g. yield from 25 g. PhSbCl, b₁₈, 174–7°, mol. wt. in C₆H₆, 283, d₄²⁰ 1.2134, n_D²⁰ 1.6021, n_F–n_C²⁰ 0.02399, does not add MeI or EtI after 10 hrs. at 100°, does not fume in the air but oxidizes energetically. *Chloride*, prisms from CCl₄, m. 144°. *Bromide*, prisms from CCl₄, m. 148°. *Ethyl-diphenylstibine* (yield, 10–1 g.), b₁₈, 190–2°, mol. wt. in C₆H₆, 291, d₄^{19.6} 1.3541, n_D^{20.8} 1.6309, n_F–n_C^{20.8} 0.02732, does not add MeI or EtI after 10 hrs. at 100°, hardly fumes in the air but oxidizes energetically. *Chloride*, plates from CCl₄, m. 163–4°. *Bromide*, monoclinic tables from CCl₄, m. 158°.

CHAS. A. ROULLER.

α,β-Diantipyrylurea, its derivatives and physiological properties. MAXIMILIAN GÖTLER. Winnenden (Württemberg). *Ber.* 48, 1765–70(1915).—*α,β-Diantipyrylurea* (a) is obtained in 16 g. yield when 20 g. 4-aminoantipyryne (b) in 300 cc. PhMe at 50° is slowly treated with 40 g. of a 20% soln. of COCl₂ in PhMe and the voluminous yellow to scarlet ppt. boiled 20 min. in the PhMe, whereby torrents of HCl are evolved and the ppt. balls up to a viscous brown resin; after cooling, the product is sepd. from the PhMe, treated with H₂O and dil. soda and crystd. from MeOH; it m. 259–60°. The PhMe on evapn. leaves a few crystals of (a) and a little yellow oil, probably *anti-pyrylurea chloride* (c), giving with alc. the prisms, m. 206–7°, of antipyrylurethan. The voluminous ppt. first formed, if quickly filtered and dried protected from the air, then treated (1 g.) with 1 cc. alc., evolves CO₂ and (b)-HCl seps.; the mother liquors with H₂O and soda give only 0.18 g. (a). The formation of (c) or (a) therefore is due to a further action of COCl₂ on the addition product CO[OC:C(NH₂).CMe:N(MeCl).NPh]₂.

(a) heated with Millon's reagent gives a yellow, then a red color and deposits a dirty red ppt.; the slightest traces in H_2O color $FeCl_3$ deep red; the reaction is also given in very dil. mineral acids while stronger acids prevent the formation of the red color. Of the salts, only the *hydriodide*, (a).1.5HI.EtOH, crystals; it seps. from alc. in olive-green needles, quickly weathering and turning Cu-red in the air, m. $225-6^\circ$, and, free from EtOH, crystd. from AcOH, m. $210-1^\circ$, loses I when heated with H_2O . *Mono-phenyldiantipyrylurea*, $C_{11}H_{11}ON_2NHCONPhC_{11}H_{11}ON_2$, from equal parts (a) and $PhNH_2$ heated 15 min. at $170-5^\circ$ in 68% yield, m. $240-1^\circ$ (decompn.), also obtained, together with brick-red needles, m. 158° , from equal parts (a) and $PhNHNH_2$ heated 10 min. at $190-5^\circ$. *Mono-p-tolyldiantipyrylurea*, hair-like needles from alc., m. 235° . *p-Ethoxyphenyldiantipyrylurea*, obtained together with a substance m. $208-9^\circ$ from equal parts (a) and *p*-EtOC $_6$ H $_4$ NH $_2$ heated 1 hr. at 180° , m. $234-5^\circ$. *p-Methoxy homolog*, needles from alc., m. 200° . *N,N'-Diantipyryldiethylbarbituric acid*, obtained in 6 g. yield from 8 g. (a) in 90 g. $CHCl_3$ heated 8 hrs. on the H_2O bath with 4 g. $CEt_3(COCl)_2$, evapd., digested with dil. HCl (which removes 1.7 g. unchanged (a)), then with dil. soda and crystd. from AcOH- H_2O or alc.-AcOH, needles, m. $312-3^\circ$. Expts. on animals (mostly rabbits) showed that the above compds. have distinct antipyretic action in doses of 0.5 g. and more; collapse never occurred even with very large doses (up to 3 g.). No central nervous effects were observed, even with dogs. In a 1700 g. rabbit given 0.25 g. (a) *per os* at 11.20 A.M. and again at 4.30 P.M. and killed the following day at 9 A.M., only 0.05 g. (a) was found in the contents of the stomach and intestines and in the feces.

CHAS. A. ROUILLER.

Color dimorphism in stilbene derivatives. PAUL PFEIFFER, with S. BRAUDE, J. KLÉBER, G. MARCON AND P. WITKOP. Univ. Zurich. *Ber.* 48, 1777-809(1915).—Nitromethoxystilbenes in many cases are capable of existence in a yellow and in an orange form; there is no general method of prepn. of one particular form and the conditions have to be established in each case; there is no regularity in the relative stability of the 2 forms; in no case can the 2 forms be distinguished by means of their m. ps. as in almost all cases before the m. p. is reached, the form which is labile at that temp. rearranges into the stable form; the solns. of the 2 forms are identical in color. So far it has not been possible to prove color dimorphism in *o*- and *m*-methoxystilbenes and in nitrostilbenes with Me and NMe $_2$ groups, but the great differences between the colors of nitrodimethylaminostilbenes and their solns. are a hopeful indication of the possibility of obtaining 2 differently colored forms in these cases also. The colors of the solns. of these compds. vary greatly with the solvent; they generally lie between greenish yellow and orange, being less deep in C_6H_6 , somewhat deeper in AcOH and alc. and deepest in CCl_3CO_2H . This change in color with solvents is characteristic of unsatd. NO $_2$ compds. and is not due to the stilbene structure or the MeO groups of the compds. above. Just as in the case of unsatd. ketones, these compds. with strong acids form more or less deeply colored solns. and with metallic salts give color reactions. That these different colors in solns. and with salts are due to the formation of addition compds. with the solvent or salt was shown by the isolation of such addition products; the deepening in color produced by these addition compds. is explained in the same way as the halochromism phenomena in ketones (*C. A.* 5, 3581), *vis.*, that the solvent mols. are coordinatively combined with the NO $_2$ groups (probably with their O atoms). To explain the differently colored forms of the solid nitromethoxystilbenes, P. has recourse to his recent theory as to the structure of crystals (*C. A.* 9, 3000), according to which crystals are merely mol. compds. containing a large number of mols.; in the orange forms P. believes the mols. are so combined that the NO $_2$ group of 1 is coordinatively combined with the unsatd. C atom of another just as in the colored compds. of aromatic NO $_2$ derivs. with phenol ethers, while in the yellow forms the same groups

of the individual mols. mutually sat. each other more or less completely in a kind of loose polymerization (as in butadienes, NO compds., etc.). *allo-2,4-Dinitrostilbene*, obtained in 0.25 g. yield from 3 g. ordinary 2,4-(O₂N)₂C₆H₃CH:CHPh (a), m. 140°, in 50 cc. xylene kept 2 days in a quartz flask 2-3 cm. above a Heraeus quartz Hg-vapor lamp, then boiled a short time with charcoal, evapd. on the H₂O bath and the final fractions crystd. from AcOH, lemon-yellow tables, m. 127°, depresses the m. p. of (a) to 106°; exposed to sunlight in CHCl₃ in the presence of a little I, it reforms (a). 2-Nitro-4-isovalerylaminostilbene, in 12 g. yield from 10 g. of the 4-NH₂ compd. warmed 3 hrs. on the H₂O bath with 8 g. EtCHMeCOCl, lemon-yellow needles from C₆H₆, m. 139°; short boiling with aq. KOH gives no red color. 4-Nitro-4'-methylstilbene, in 0.6 g. yield from 3.4 g. *p*-O₂NC₆H₄CH₂CO₂H, 2.2 g. *p*-MeC₆H₄CHO and a little piperidine heated 2.5 hrs. at 140°, greenish yellow leaflets from alc., m. 150°. 2-Nitro-4'-methoxystilbene is obtained in 0.5 g. yield when 10 g. of the 4-NH₂ compd. (see below) in 200 cc. alc. are slowly treated with turbinine with 5 g. concd. H₂SO₄, then, with stirring and cooling, with 6 g. AmNO₂ containing a little alc., allowed to stand 2 hrs., filtered and broken up on clay and 5 g. of the *diazonium sulfate*, Bordeaux-colored leaflets with golden luster, deflagrates 165°, is added in small portions to 100 cc. boiling alc. containing 3 drops H₂SO₄, boiled 20 min., freed from alc. on the H₂O bath, and distd. with steam at 150°; it seps. from alc. in long, dark yellow needles, m. 88-90°. 4-Nitro-4'-methoxystilbene, obtained in 50% yield of the *p*-O₂NC₆H₄CH₂CO₂H used when 1.9 g. of this acid, 1.4 g. *p*-MeOC₆H₄CHO and 15 drops piperidine are heated 1 hr. (reaction begins at about 100° and at 130° there is energetic evolution of CO₂), m. 132-4° after repeated crystns. from AcOH, from which it seps. in leaflet-to-table-like yellow crystals with orange tinge; from a concd. C₆H₆ soln. ligroin ppts. leaflets of the same color, while a dil. soln. treated with low boiling ligroin and quickly shaken often gives a network of greenish yellow slender needles; the latter change from greenish to orange yellow at about 100° and then m. 132-4°. 4-Amino-4'-methoxystilbene, from the NO₂ compd. with SnCl₂, brownish yellow leaflets from alc., m. 173-4°; *acetyl derivative*, in 0.6 g. yield from 0.5 g. of the amine heated 3 hrs. on the H₂O bath with 10 g. Ac₂O, leaflets from alc., m. 237°; *benzoyl derivative*, in 1.1 g. yield from 1 g. amine and 6 g. BzCl after 3 hrs. on the H₂O bath, leaflets from AcOH, m. 249°. 4-Nitro-3'-methoxystilbene, from *m*-MeOC₆H₄CHO, *p*-O₂NC₆H₄CH₂CO₂H and piperidine heated 3 hrs. at 160°, yellowish leaflets from alc., m. 87°. 4-Nitro-2'-methoxystilbene, in 1 g. yield from 1.5 g. *o*-MeOC₆H₄CHO, 1.9 g. *p*-O₂NC₆H₄CH₂CO₂H and piperidine heated 0.5 hr. at 120°, canary-yellow needles from alc., m. 122°, becomes dull in the air. 4-Nitro-4'-dimethylaminostilbene, red leaflets with blue surface luster from C₆H₆, m. 250-1°, sol. in C₆H₆ with golden yellow color and yellow fluorescence; addition of ligroin changes the color to greenish yellow and the fluorescence to green; 0.01 g. dissolves in 1 cc. of C₆H₆, alc., AcOH and CCl₃CO₂H with golden yellow, yellow-orange, orange-red and light greenish yellow color, resp. 2-Cyano-4-nitro-4'-methoxystilbene, from 2,4-NC(O₂N)₂C₆H₃Me, *p*-MeOC₆H₄CHO and piperidine heated 1-1.5 hrs. at 140-50° and crystd. from AcOH, orange-red leaflets, m. 198°. An AcOH soln. satd. at room temp., cooled to 0° and poured into cold H₂O, deposits a yellow pulverulent ppt. which does not lose wt. in a drying oven, assumes a distinctly orange tinge above 170°, becomes completely orange 180° and m. 196°. 4-Cyano-2-nitro-4'-methoxystilbene (see P. and Braude, *Ann.* 1915); the yellow form is obtained with certainty when a hot concd. C₆H₆ or AcOH soln. is quickly cooled, when it seps. in pure yellow leaflets; if the suspension of the yellow form in C₆H₆ is allowed to stand at room temp. it begins to change in a few hrs. to orange prisms which are obtained directly when a C₆H₆ or AcOH soln. is allowed to evap. slowly at room temp. A C₆H₆ soln. satd. at room temp. and allowed to evap. at 5° deposits pure yellow tablets weathering in the

air, with loss of 0.5 mol. C_6H_6 , to an orange powder. The orange form m. $157-8^\circ$; the yellow form becomes orange in a few min. at $120-5^\circ$ and then m. $157-8^\circ$; at room temp. both forms are stable for months, even in direct sunlight. Exposed 1 week to Br vapors, both the orange and yellow forms yield the same *tribromide*, leaflets from AcOH, m. $210-1^\circ$. Treated in hot C_6H_6 with 2.5 parts anhydrous $SnCl_4$ and cooled in a closed vessel, the stilbene gives the *addition compound* $2C_{10}H_{12}O_2N_2 \cdot SnCl_4$, orange crystals regenerating with H_2O or dil. HCl an orange-yellow nitrile; similarly, on cooling a hot $PhNH_2$ soln. of the nitrile is obtained the *compound* $2C_{10}H_{12}O_2N_2 \cdot PhNH_2$, in orange crystals giving on the H_2O bath or with dil. HCl at room temp. an orange powder. *Methyl 2-nitro-4'-methoxystilbene-4-carboxylate*, in 2.8 g. yield from 5 g. of the nitrile suspended in 200 cc. MeOH and treated on the H_2O bath with HCl for 2 hrs., long, slender, yellow needles from MeOH, m. $117-8^\circ$, becomes distinctly orange at $100-5^\circ$; after heating some hrs. at $100-5^\circ$ and cooling it remains permanently yellow-orange; this form is obtained cryst. when the heated product is recrystd. from MeOH, care being taken that a little remains undissolved; it gradually seps. in broad, flat, orange-yellow needles, m. $117-8^\circ$; a hot concd. MeOH soln. quickly cooled deposits the yellow needles. *Ethyl ester*, obtained in 4.5 g. yield from 4 g. of the nitrile, pure yellow, slender needles from hot alc., m. $103-4^\circ$ without becoming orange; if a suspension in alc. in a covered vessel is allowed to stand for weeks a part changes into orange tablets which are isolated by warming cautiously until the yellow crystals disappear and decanting hot; they m. $103-4^\circ$ to an orange-yellow liquid solidifying to a yellow cryst. mass. A hot alc. soln. of the orange crystals quickly cooled deposits the yellow form; the 2 forms do not depress each other's m. p. *Free acid*; the *yellow form* is obtained by boiling 2 g. of the Et ester in 120 cc. AcOH, 50 cc. H_2SO_4 and 50 cc. H_2O for 2-3 hrs.; it seps. from AcOH in needles, from alc. in leaflets, m. 250° to an orange liquid, sol. in AcOH with yellow but in CCl_3CO_2H with orange color. A hot C_6H_5N soln. deposits on cooling the *pyridine salt* in pure yellow needles which, when cautiously heated in thin layers at $90-100^\circ$, leaves the *orange form* of the acid as an orange powder, turning yellow at 140° and m. 250° . A suspension of 1 g. of the acid in 20 cc. hot H_2O treated with aq. K_2CO_3 until almost dissolved, filtered and evapd. yields the *potassium salt*, sepg. from hot H_2O in orange leaflets or needles with 2 H_2O , stable in the air, also obtained from an aq. soln. evapd. at room temp.; over P_2O_5 it goes over into a *monohydrate* and at 100° into a red-orange *anhydrous form*; aq. solns. are yellow-orange, Me_2CO and alc. solns. containing a little H_2O greenish yellow. The *sodium salt*, from an aq. suspension of the acid and a slight excess of soda, exists in several forms; homogeneous long yellow needles with 5 H_2O , stable for days in the air, are obtained when the soln. satd. at room temp. is slowly allowed to evap. at room temp.; on heating it loses its H_2O and becomes brown-orange. A hot concd. aq. soln. quickly cooled in general deposits brown-orange leaflets with 6 H_2O , weathering in the air to a yellow *dihydrate*; a form apparently identical with the latter is obtained when a hot concd. aq. soln. is slowly cooled. *4-Cyano-2-nitro-2'-methoxystilbene*, in 2.7 g. yield from 2 g. $2,4-O_2N(NC)C_6H_3Me$, 1.8 g. $o-MeOC_6H_4CHO$ and a few drops piperidine heated 1.5-2.0 hrs. at 100° , yellow needles from hot AcOH, m. 183° , sol. in AcOH and C_6H_6 with greenish yellow, in CCl_3CO_2H with orange-yellow color. *Ethyl 2-nitro-2'-methoxystilbene-4-carboxylate*, in 2.8 g. yield from a suspension of 3 g. of the nitrile in 250 cc. alc. treated 3 hrs. on the H_2O bath with HCl, slender yellow needles from alc., m. 101° ; the mother liquors deposit on slow evapn. yellow leaflets of the same m. p.; it is sol. in C_6H_6 and AcOH with greenish yellow, in CCl_3CO_2H with orange-yellow color. *4-Cyano-2-nitro-3',4'-methylenedioxy stilbene*, in 7.5 g. yield from 6 g. $2,4-O_2N(NC)C_6H_3Me$, 6 g. piperonal and 2 g. piperidine heated 1.5-2.0 hrs. at 150° , yellow-orange needles from AcO

2° , sol. in C_6H_6 , AcOH and

Me_2CO with yellow, in $\text{CCl}_4\text{CO}_2\text{H}$ with bright orange color. *2,4-Dinitro-4'-methoxystilbene* (see P. and Kléber, *Ann.* 1915) occurs only in a red form; 0.01 g. dissolves in 2 cc. of C_6H_6 and $\text{CCl}_4\text{CO}_2\text{H}$ with greenish yellow and orange color, resp.; the C_6H_6 soln. on evapn. gives the compound $2\text{C}_{18}\text{H}_{12}\text{O}_5\text{N}_2\cdot\text{C}_6\text{H}_6$ in orange-red prismatic crystals, losing the C_6H_6 without change in color on heating. *Aniline compound*, $2\text{C}_{18}\text{H}_{12}\text{O}_5\text{N}_2\cdot\text{PhNH}_2$, orange-red needles losing the PhNH_2 on heating. PhNMe_2 forms no addition product. *2-Nitro-4-amino-4'-methoxystilbene*, in good yield from the 2,4-(NO_2)₂ compd. in alc. treated 4 min. with NH_3 , then with H_2S until almost all has dissolved and the liquid is deep red, Bordeaux-red needles from C_6H_6 , forms a thick red melt at 154° , liquefies 157° ; 10 g. heated 1 hr. on the H_2O bath with excess of Ac_2O , dild. with an equal vol. of H_2O and again heated 1 hr. gives 11 g. of the *acetyl derivative*, yellow needles from C_6H_6 , assumes an orange tinge at 170° , m. 181° to an orange-red liquid; in 1 expt. a C_6H_6 soln. quickly cooled deposited bright orange-red leaflets turning orange-yellow at about 130° and m. 182° ; the expt. could not be repeated, but by heating hot C_6H_6 solns. of the yellow form with the orange-red leaflets once obtained the latter could now be obtained as desired. From hot alc. or AcOH the Ac deriv. seps. in orange-yellow crystals, probably a mixed form of the yellow and orange-red isomers. *Benzoyl derivative*, in 12 g. yield from 10 g. of the amine heated 1 hr. on the H_2O bath with 15 cc. BzCl , treated with 50 cc. alc. and heated 15 min. longer, pure yellow leaflets or needles from alc., C_6H_6 , BzMe , PhNH_2 or PhNMe_2 , m. 172° , first becoming orange-red; heated on the H_2O bath under a reflux condenser with a little PhMe it changes in a few hrs. to orange-red crystals, more of which sep. from the PhMe if it is cooled slowly on the H_2O bath; if cooled rapidly, however, the mother liquor solidifies to yellow needles. The orange-red crystals m. 172° , do not weather on heating and when recrystd. from hot C_6H_6 yield the yellow needles; the same change slowly occurs under C_6H_6 at room temp. A hot AcOH soln. of the Bz deriv. deposits on cooling yellow needles with 1 mol. AcOH , become red-orange $110\text{--}20^\circ$ and m. $167\text{--}8^\circ$. In the same way is obtained a *trichloroacetic acid compound*, orange leaflets, m. $115\text{--}21^\circ$, weathering on the H_2O bath to a yellow powder, m. $169\text{--}70^\circ$. *2-Cyano-4-nitro-4'-dimethylamino-stilbene*, in 1 g. yield from 1.5 g. $2,4\text{-NC(O}_2\text{N)}\text{C}_6\text{H}_3\text{Me}$, 1.4 g. $p\text{-Me}_2\text{NC}_6\text{H}_4\text{CHO}$ and 15 drops piperidine heated at $120\text{--}30^\circ$, almost black leaflets with greenish luster from AcOH , m. $209\text{--}10^\circ$, sol. in AcOH and C_6H_6 with deep orange-red color; the dil. orange C_6H_6 soln. shows orange fluorescence. *4-Cyano-2-nitro-4'-dimethylaminostilbene*, black-green needles from AcOH , m. 178° , sol. in AcOH , alc. and C_6H_6 with deep red, in $\text{CCl}_4\text{CO}_2\text{H}$ with greenish yellow color, pptd. unchanged by ligroin from C_6H_6 and by H_2O from AcOH . *2,4,6-Trinitro-4'-methoxystilbene*, long brick-red needles from AcOH , m. $168\text{--}9^\circ$, sol. in AcOH and C_6H_6 with orange-yellow, in $\text{CCl}_4\text{CO}_2\text{H}$ with red-orange color. *2,4,6-Trinitro-4'-chlorostilbene*, brown-yellow leaflets from AcOH , m. $154\text{--}5^\circ$, obtained in 2.2 g. yield from 4.4 g. $(\text{O}_2\text{N})_3\text{C}_6\text{H}_3\text{Me}$, 2.8 g. $\text{ClC}_6\text{H}_4\text{CHO}$ and a little piperidine heated 0.5 hr. at 120° .
C. A. ROUILLER.

Genetic relationships of the optically active forms of β,β' -iminodibutyric acid and β -aminobutyric acid. II. HELMUTH SCHEIBLER AND J. MAGASANIK. Berlin. *Ber.* 48, 1810-15 (1915); cf. C. A. 6, 2933.—The *meso*- β,β' -imino acid, after standing 1 year in a closed vessel, solidified to a cryst. mass which, dissolved in boiling alc., concd. on the H_2O bath to a syrup, treated with an equal amt. of warm MeOH and seeded after cooling, gave microscopic, ill-characterized crystals, m. $177\text{--}8^\circ$ (decompn.), i. e., 2° lower than the active but considerably higher than the racemic compd., while the *meso*-di-Me ester hydrochloride and chloroplatinate m. lower than the corresponding racemic derivs., a further indication that the racemic compd. is not a true racemate but a mixt. of equal parts of the active forms. The *meso*-dimethyl ester (a), b₁₀ 130° , is obtained from the mother liquors of the racemic chloroplatinate, the hydrochloride,

after recrystn., being treated in just enough cold MeOH with NH_3 in MeOH, then with Et_2O as long as NH_4Cl is pptd., filtered, freed from Et_2O , dried with Na_2SO_4 and fractioned. Heated 1 hr. under a reflux condenser with excess of MeI and freed from the MeI by evapn. it gives *dimethyl N-methyl- β,β' -iminodibutyrate iodide* as a syrup, from which the free ester is liberated in the same way as (a). Of its derivs. only the *benzyl iodide addition product* was obtained in cryst. form. If the theory of the pseudoasym. C. atom (Fischer, *Ber.* 24, 4224(1891)) can also be extended to a N atom with correspondingly arranged groups, 2 isomeric forms should be capable of existence in this case also and as a matter of fact a part of the product remained syrupy. To study further the mechanism of the resolution of the β -imino acid by NH_3 , the action of aq. NH_3 on the active *N-methyl- β -imino acid* should be tried and as this might give active or inactive *β -methyl-aminobutyric acid* (b) and $\text{MeCH}(\text{NH}_2)\text{CH}_2\text{CO}_2\text{H}$, (b) was prepd. by heating 3.5 g. crotonic acid with 20 cc. of 25% aq. MeNH_2 24 hrs. at 140° , concd. on the H_2O bath, evapd. several times with alc., dissolved in a little warm alc., seeded with crystals obtained as described below and gradually treated with Et_2O ; yield, 1.3 g. It was also obtained by heating 15 g. $\text{MeCHClCH}_2\text{CO}_2\text{H}$ with 20 g. of 10% alc. MeNH_2 2 hrs. at 100° , evapg. *in vacuo*, dissolving in H_2O , heating 15 min. on the H_2O bath with excess of $\text{Ba}(\text{OH})_2$, evapg. *in vacuo*, again heating with H_2O on the H_2O bath, repeating the operation until the odor of MeNH_2 was no longer perceptible, removing the Ba with H_2SO_4 , evapg. *in vacuo*, then several times with MeOH, satg. in dry MeOH with HCl, allowing to stand 24 hrs., evapg. *in vacuo*, repeating the esterification, removing the excess of HCl by repeated evapn. with MeOH, treating in an equal amt. of cold MeOH with NH_3 , adding Et_2O , filtering from the NH_4Cl , evapg. *in vacuo*, dissolving in a little Et_2O , drying with Na_2SO_4 and fractionating. The *methyl ester* b_{15} 66° . Boiled 4 hrs. with 10 parts H_2O and evapd. it gives the free (b) as a syrupy crystg. on standing; evapd. in MeOH, at once treated with 10 parts warm EtOH and allowed to stand 12 hrs. in the ice chest it gives 2.8 g. (b). At the same time considerable $\text{MeCH}(\text{OH})\text{CH}_2\text{CONHMe}$ is formed, probably due to the intermediate formation of β -butyrolactone (cf. Johansson, *C. A.* 9, 2651). To obtain the active forms, the active *β -chlorobutyric acids* were prepd.; 20 g. of the *dl*-acid and 64.8 g. quinine in 100 cc. each of MeOH and H_2O are evapd. to 0.5 vol. not above 25° , giving an oil which, on seeding and rubbing, crysts.; it is drained off, treated twice in the same way with 75 cc. of MeOH and H_2O and the 48.5 g. of salt thus obtained is crystd. from 50 and 40 cc. of H_2O after evapn. of the MeOH used for soln., then treated in 40 cc. MeOH with H_2O to turbidity and allowed to stand 48 hrs. in the ice chest; a repetition of the process gives 16 g. of well defined crystals which, cautiously decompd. with cold dil. H_2SO_4 and extd. with Et_2O , gave the *l*-acid, the mother liquors yielding the *d*-form, which forms a difficultly sol. brucine salt. The crotonic acid used in the work was obtained in 54.5% yield by treating 100 g. malonic acid in 135 g. cold alc. and 86 g. $\text{C}_6\text{H}_5\text{N}$ with 85 g. AcH in 2-3 portions in the course of 0.5 hr., warming gently until reaction began, at once removing the source of heat until bubbles were no longer formed, repeating the operation several times and finally warming 3-4 hrs. on the H_2O bath, cooling, making acid to Congo with cold dil. H_2SO_4 and extg. with Et_2O .

CHAS. A. ROUILLER.

Chemical constituents of the bituminous tar oils rich in sulfur (ichthyol oils). I. HELMUTH SCHEIBLER. Berlin. *Ber.* 48, 1815-26(1915).—The work reported in this paper was done on a crude oil from southern France. On distn. under diminished pressure the 1st fractions distil over smoothly but as the temp. rises the oil begins to foam and there is strong decompn. All the fractions, especially the high boiling ones, form with Na dark insol. products and contain not only strongly acid substances (org. acids, phenols and mercaptans) but on decompn. with H_2O yield volatile oils insol.

in aq. alkalis, having an unpleasant odor and showing a strong tendency to condense; they are apparently hydrocarbons with acid methylene groups. If the crude oil is treated with Na and washed with dil. HCl, there is obtained a lighter colored oil which has lost the disagreeable odor and can be distd. *in vacuo* without decompn. but still contains a small amt. of substances containing O; from the latter it can be freed by means of Grignard reagents which form with the O compds. substances which again react with Na; the purified oil undoubtedly contains ketones which are converted by the Mg compds. into tertiary alcs. After decompn. of the Mg compds. and distn. over Na there is obtained a light yellow oil of pleasant odor, which contains only C, H and S and which can be sepd. into a number of fractions of very similar chem. properties. Various reactions (formation of dyes with phenanthrenequinone and H_2SO_4) indicate the presence of thiophene compds. By means of $AcCl$ and $AlCl_3$ a definite acetylthiophene was isolated. This was also obtained from the corresponding fractions of 2 crude oils from Tyrol; in fact, all three samples of crude oils yielded purified oils of identical chem. behavior, the only difference being in the relative amts. of the constituents, the typical S compds. being higher homologs of thiophene (in some cases 50% of the oil); the accompanying hydrocarbons belong chiefly to the C_8H_8 series, together with small amts. of compds. richer in H. From 500 g. crude oil were obtained 225 g. purified oil which yielded 43.9 g. b_{16} 54–70° and 10.0 g. b_{16} 70–80°; these fractions distd. under atm. pressure and then twice over Na gave 17.6 g. b_{30} 170–80°, with 75.03% C, 9.73% H, 14.33% S, d_{20} 0.901. By partial acetylation it is possible to obtain a product richer in S; thus, 10 g. of the above fraction were treated (on the assumption that 0.5 of it was propylthiophene) in 20 cc. of cold low-boiling petr. ether with 1.6 g. $AcCl$ and 2.7 g. $AlCl_3$ in alternate small portions in the course of 0.5 hr., allowed to stand 1 hr. at 0°, the resulting product washed with petr. ether, decompd. with ice, extd. with Et_2O , washed with dil. soda and H_2O , dried with $CaCl_2$ and fractionated; this gave 2.5 g. b_{14} 118–27°, with 65.62% C, 7.68% H and 17.68% S; 1 g. of this boiled 3 hrs. with a soln. prepd. by treating 1 g. $H_2NCONHNH_2 \cdot HCl$ in alc. with 0.2 g. Na in alc., cooling and filtering from the NaCl, gave 0.66 g. of a semicarbazone, $C_{10}H_{11}ON_3S$, m. 178–92°, of propylacetothienone or an isomer (trimethyl-, methylethyl- or isopropylacetothienone) or perhaps of a mixt. of isomers; as the oil from which it was obtained had the compn. of a Bu rather than a Pr deriv., it must have contained, besides propylacetothienone, higher homologs. Attempts to isolate the thiophene compds. from the oil fractions with halogens or Hg salts had but little success; treatment with Br gives also the brominated C_8H_8 derivs. and Hg salts only partially ppt. the thiophene compds. From 1 g. of a fraction b. 130–40° of a Tyrolese oil in 40 cc. alc. treated with 37 g. of 10% alc. $HgCl_2$ and 7.5 g. of 33% $NaOAc$ and allowed to stand 20 hrs. was obtained 0.55 g. crystals which, on washing with H_2O , alc., and Et_2O , yielded up 0.15 g. cryst. material to the Et_2O ; the washed crystals only partially dissolved in boiling alc. and the filtered soln. on cooling deposited leaves, m. 189–93° (Steinkopf and Bauermeister, C. A. 8, 1418, describe the $HgCl_2$ compd. obtained from α, α' -dimethylthiophene as m. 186–7°). The neutral constituents of the crude oils which combine with the Na in the purification process also contain S; they are probably compds. with mobile H atoms (condensed cyclopentadiene and thiophene rings), or perhaps compds. similar to the so-called penththiophene; cf. C. A. 9, 3245).

CHAS. A. ROULLER.

New method of preparation of allochrysoketonecarboxylic acid and its derivatives. Intramolecular Friedel-Crafts reaction in acid anhydrides. ALFRED SCHAAER-SCHMIDT, with N. IRNEU. Berlin. Ber. 48, 1826–33 (1915); cf. C. A. 9, 2256.—To study further the nature of the reduction products of 1-benzoylanthraquinones it was desirable to extend the reaction to similarly constituted polyketones like 1-benzoylfluorenone. With the purpose of obtaining such compds. it was attempted to condense

1-phenylnaphthalene-2,3-dicarboxylic anhydride (a) with aromatic hydrocarbons by means of AlCl_3 , but the hydrocarbon does not enter into reaction, the (a) undergoing an intramol. Friedel-Crafts reaction and giving exclusively allochrysoketone-carboxylic acid (b). (a) was obtained in 38 g. yield from 50 g. $\text{PhC}:\text{CCO}_2\text{H}$ gently boiled 3 hrs. with 6 parts of Ac_2O ; 60 g. of the finely powdered (a) suspended in 420 cc. of C_6H_6 are treated in the course of 0.5 hr. with 100 g. AlCl_3 , heated 4 hrs. at 70° with frequent shaking, poured upon ice, freed from C_6H_6 by distn., boiled twice with dil. HCl , then with 8 l. H_2O and 80 cc. NH_4OH , filtered boiling hot and treated hot with dil. HCl , which gives 59–60 g. of (b) as a voluminous ppt. sepg. from xylene in Bordeaux-red needles, m. $288-9^\circ$, sublimes 260° in rodlets which, like the crystals, are yellow in transmitted and red in incident light. From 50 g. (a) suspended in 200 cc. PhMe gently boiled 0.5 hr. with 42 g. PCl_5 , dild. with 150 cc. more PhMe , brought to a boil and filtered hot is obtained 43 g. of the chloride, golden yellow needles, m. $194-5^\circ$; 6.3 g. of this in 70 cc. PhCl slowly treated at room temp. with 8 g. AlCl_3 , allowed to stand 0.5 hr. and then heated 1 hr. at $60-70^\circ$ gives 7 g. of 1-*p*-chlorobenzoylallochrysoketone, golden yellow needles from AcOH , m. 220° , sol. in concd. H_2SO_4 with brownish red color unchanged by gently warming with Cu powder; H_2O gives a yellow ppt. 1-Dimethylbenzoylallochrysoketone, from the chloride, *m*-xylene and AlCl_3 heated 1.5 hrs. at $70-80^\circ$, orange-yellow plates from AcOH , m. 212° , sol. in H_2SO_4 with brown-red color unchanged by warming with Cu powder. Methyl ester of (b), from the chloride boiled 15 min. with 10 parts MeOH , orange needles from MeOH , m. $146-7^\circ$; Et ester, from the chloride and EtOH or from the Ag salt boiled 3 hrs. in 20 parts C_6H_6 with 2 parts EtI , orange needles from alc., m. $182-3^\circ$. The Ag salt, which is pure yellow when fresh, becomes brown-red on long standing in the light. When gently boiled 0.5 hr. with 2 parts Zn dust and 20 parts NH_4OH , (b) gives a compound $\text{C}_{18}\text{H}_{12}\text{O}_4$, hair-like needles from AcOH , turns brown 225° , m. $244-6^\circ$; apparently the C:O group has been reduced to the alc.

CHAS. A. ROULLER.

Imide character of hydrazoic acid. I. Synthesis of azidodithiocarbonic acid FRITZ SOMMER. Berlin. Ber. 48, 1833–41(1915).—Salts of HN_3 react with CS_2 to form the compds. $\text{N}_3:\text{NCS}_2\text{M}$. Thus, when 6 g. NaN_3 in 25 cc. H_2O are slowly treated at $40-50^\circ$ with 7.5 g. CS_2 , filtered, concd. over P_2O_5 and slowly cooled to 0° there is obtained a good yield of long, highly refractive prisms becoming yellowish on long standing and weathering in the air at room temp. and having the compn. $\text{N}_3\text{CS}_2\text{Na}$, $4\text{H}_2\text{O}$ of sodium azidodithiocarbonate; they are stable in closed vessels below 10° and only moderately explosive in the hydrated form, as they cannot be made to explode by shock but deflagrate violently on a Pt foil; the anhydrous salt can be exploded by shock and detonates loudly on gentle heating. Potassium salt, similarly prepd., exploded violently while being freed from the mother liquors by cautiously spreading on clay with a porcelain spatula. After pressing out between paper it had the appearance of leaflets and was probably anhydrous, as small samples did not lose wt. over H_2SO_4 . Barium salt refractive hexangular tables with 5 H_2O , very stable in the air and with about the same degree of explosiveness as the Na salt. Qual. expts. on the heavy metal salts (they are fearfully explosive) showed that they are of a very complex nature (many are insol. in acids but sol. in org. solvents and the color of the solns. differs from that of the metal ion). Thus, the Na salt and AgNO_3 give a white curdy Ag salt sol. in excess of the Na salt, insol. in HNO_3 and NH_4OH , explodes on the least touch when dry. Cu^+ salt give a dark dirty green-brown ppt. changing to a Cd-yellow with excess of the Na salt the yellow salt is insol. in half-dild. HCl and HNO_3 but sol. in NH_4OH with green an in excess of azido salt with yellow color. Hg^+ salts give an amorphous white ppt. slowly becoming cryst., sol. in dil. HCl , with difficulty in cold dil. HNO_3 , easily in NH_4OH an org. solvents and in excess of HgCl_2 or azido salt. HgNO_3 gives a black-gray pp

becoming white on addition of more HgNO_3 but unchanged by excess of azido salt, sol. in dil. HCl , insol. in cold dil. HNO_3 . $\text{Pb}(\text{OAc})_2$ gives a yellowish white ppt. sol. in cold dil. HCl and HNO_3 ; the same is true of TlNO_3 . The Cd salt forms needles sol. in excess of azido salt, in cold dil. HCl and HNO_3 and in NH_4OH , but insol. in dil. AcOH . $\text{Bi}(\text{NO}_3)_3$ gives a Cd-yellow salt sol. in excess of azido salt with red-yellow color, sol. in cold dil. HNO_3 , dil. HCl and AcOH . SnCl_2 in HCl gives no ppt.; the same is true of Al , Cr , Fe'' , Ni , Co and Mn salts. ZnSO_4 gives a white salt insol. in excess of azido salt but sol. in HCl , HNO_3 and AcOH . Ce'' and Th salts give no ppt. FeCl_3 gives needles free from Fe , and the liquid contains Fe'' but no Fe''' ions; a similar oxidation is effected by KMnO_4 , $\text{K}_2\text{Cr}_2\text{O}_7$, Ce'' salts in H_2SO_4 and I in KI ; undoubtedly the disulfide $[\text{N}_2:\text{NC}(:\text{S})\text{S}-]_2$ is formed; if the needles are heated in a test tube in aq. suspension, the tube is shattered before the H_2O reaches the b. p. C. A. R.

An oxidation product of indigo blue. P. FRIEDLÄNDER AND N. ROSCHDESTWENSKY. Darmstadt. Ber. 48, 1841-7 (1915); cf. C. A. 3, 1268.—As previously pointed out, indigo and other indigoid dyes are slowly oxidized when boiled in contact with air in high-boiling solvents. On boiling a few mg. indigo in 1-2 cc. of $\text{o-C}_6\text{H}_4(\text{CO}_2\text{Et})_2$ (b. 295°) and shaking, the blue color disappears in a few min. and changes to a brownish yellow, and on long standing small amts. of difficultly sol. crystals sep. In boiling phenanthrene (b. 340°) in a current of air the change is still more rapid; 1 g. indigo in 20-30 g. phenanthrene is completely destroyed in about 0.5 hr., giving chiefly a dark brown, amorphous, difficultly sol. product, and in smaller amt. a yellow compd. distg. over with the phenanthrene and coloring it brownish yellow; it was not isolated in solid form but the reactions of the phenanthrene soln. make it probable that it is identical with the compd. $\text{C}_{18}\text{H}_{14}\text{O}_2\text{N}_2$ (a) obtained by Perkin by sublimation of indigo in the presence of a limited amt. of air (P. Chem. Soc. 22, 198 (1906)). A direct comparison of (a) with the compd. $\text{C}_{18}\text{H}_{14}\text{O}_2\text{N}_2$ obtained from indigo or isatin with KMnO_4 (Meister, Lucius & Brining, C. A. 9, 966, 1999) showed that they are identical and confirmed the correctness of P.'s formula. On warming with strongly acid SnCl_2 it gives white needles of the HCl salt, dissociated by H_2O , of an easily oxidizable, faintly basic reduction product which is brownish yellow and sol. in cold dil. NaOH to the vat dye obtained with hyposulfite. The presence of a $\text{C}:\text{O}$ group in (a) is further indicated by the formation of an oxime, faintly yellowish needles, m. about 265° (decompn.), sol. in warm dil. NaOH and concd. (1:1) HCl , and of a phenylhydrazosone, orange-yellow needles, m. 242° . Shaken with 5% NaOMe (a) gradually dissolves without color and H_2O reprecipitates it; on warming the soln. becomes violet-blue, then, owing to reduction, brown, shaking with air restoring the blue color; in greater concns., violet-black needles sep. which in contact with H_2O slowly regenerate (a). In boiling 10% aq. NaOH it slowly dissolves without color and becomes yellow-red on addition of H_2SO_4 ; extrn. with AcOEt removes isatin while the acid soln. contains an equiv. amt. of $\text{o-H}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$. The conclusion drawn from these facts that (a) is anhydro- α -isatinanthranilide,

$\text{C}_6\text{H}_5-\text{C}(\text{CO}:\text{N})-\text{C}(\text{N}:\text{CO})-\text{C}_6\text{H}_5$, is confirmed by the fact that it is obtained in the following

ways: α -Isatinilide and somewhat more than 1 mol. of $\text{H}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ in sufficient AcOH are heated until the originally brown-yellow soln. no longer becomes a brighter yellow; a dehydrating agent (Ac_2O , H_2SO_4 + AcOH) is added, whereupon the warm mixt. solidifies to a magma of yellow needles of (a). Again, 2 mols. of $\text{H}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ in enough boiling xylene treated with 1 mol. isatin chloride deposits $\text{HCl}\cdot\text{H}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ and the xylene soln. on cooling solidifies to a magma of (a). Finally, (a) is obtained from $\text{o-ONC}_6\text{H}_4\text{CO}_2\text{H}$ and indoxyl in faintly alk. soln., subsequently warmed and acidified.

Calcium in permeability and irritability. JACQUES LOEB. Rockefeller Inst. *J. Biol. Chem.* 23, 423-30(1915).—The variation of the amt. of Ca, or of Ca + Mg, required to antagonize various concns. of NaCl, or of NaCl + KCl, was investigated for a case in which the antagonism concerned permeability (eggs of *Fundulus*), and for a case in which it concerned irritability (larvae of *Balanus eburneus*). It was found that in the case of irritability the Ca required varied in direct proportion to the change in the concn. of NaCl (Weber's law), while in the case of permeability the concn. of Ca required for antagonism varied approx. as the square of the ratio of the concn. of NaCl.

The time required for reduction of oxyhemoglobin in vivo. D. FRASER HARRIS AND H. J. M. CREIGHTON. *J. Biol. Chem.* 23, 469-70(1915).—If a spectroscope is directed to the red glare between 2 adjoining fingers placed before a bright light, the 2 bands of oxyhemoglobin can be detected. If the wrist be tightly bandaged, these fade away and are replaced by the single band of hemoglobin in from 18 to 26 seconds. The same change in the rabbit's ear requires about 40 seconds. The reduction by tissues, *in vitro*, requires from 2 to 2.5 min.

I. GREENWALD.

The refractive indices of solutions of certain proteins. IX. Edestin. CARL A. SCHMIDT. Univ. Calif. *J. Biol. Chem.* 23, 487-93(1915).—Edestin, in varying amts., was dissolved in solns. of acids, bases and salts. These were found to follow the law $n - n_1 = a \times c$, where n is the refractive index of the protein soln., n_1 that of the solvent, c the % concn. of protein, and a a constant expressing the change in n of the solvent by the addition of 1% protein. The value of a was found to be 0.00174 and 0.00006, and remained constant even though the solvent causes hydrolysis of the protein.

I. GREENWALD.

Preparation and composition of caseinogen. JOHN MELLANBY. St. Thomas' Hospital, London. *Biochem. J.* 9, 342-50(1915).—Caseinogen was prepd. by adding 3 vols. of alc. to 1 vol. of fresh, separated milk, at a temp. below 15°. The ppt. was strained through muslin, ground up with ether, filtered, and again extd. with ether until free from fat and pigment. This product was passed between folded filter and dried in the air. The impurities present—lactose and lactalbumin—can be estimated by dissolving them in H₂O at 15°, under which conditions caseinogen is insol. Casein

ogen is probably a complex of protein and calcium phosphate; 3500 g. of caseinogen contain a gram mol. wt. of $\text{Ca}_3(\text{PO}_4)_2$. Six gram mols. AcOH ppt. acidic caseinogen from about 3500 g. of caseinogen. 1 g. atom of P is contained in about 3400 g. of acidic caseinogen. The reaction between AcOH and caseinogen is expressed thus: Protein, $\text{Ca}_3(\text{PO}_4)_2 + 6\text{HOAc} = \text{Protein}, 6\text{HOAc} + \text{Ca}_3(\text{PO}_4)_2$. The relation of the
(Caseinogen) (Acidic caseinogen)

protein to the calcium phosphate in caseinogen is suggested as $\text{R} \begin{cases} (\text{NH}_2)_2\text{Ca}_2\text{H}_2(\text{PO}_4)_2 \\ \text{XCa} \end{cases}$

in which the group (X) has feeble acidic properties. [Cameron and Seidell (*J. Am. Chem. Soc.* 26, 1454(1904)) have shown that $\text{Ca}_3(\text{PO}_4)_2$ and $\text{CaH}_2(\text{PO}_4)_2$ are considerably decomposed by water, whereas $\text{Ca}_2\text{H}_2(\text{PO}_4)_2$ is stable.] B. HOROWITZ.

Composition of "lecithin," together with observations on the distribution of phosphatides in the tissues and methods for their extraction and purification. HUGH MACLEAN. *Biochem. J.* 9, 351-78(1915).—Phosphatides extd. from tissues by alc. contain nitrogenous impurities, and these are difficult to remove by any of the ordinary methods for prepg. "lecithin." This crude lecithin is a mixt. of true lecithin—in which all of the nitrogen is in the form of chlorine—and cephalin, which contains no choline, and in which all of the nitrogen is in the form of aminoethyl alc. These two components were sepd. by precipitation as their Cd salts and extn. of the ppt. with ether. *Prepn. of "lecithin."* The tissue used (heart, kidneys or egg yolk) was ground to a fine paste, spread out in a thin layer on a glass plate, and dried at 30° (using a fan). The dried tissue was powdered in a coffee mill. The powder was extd. several times with excess of abs. alc. and the exts. united and concd. to a small vol. under reduced pressure at 40° . The residue was taken up with a small vol. of ether, in which it did not completely dissolve. To the unfiltered mixt. acetone was added in excess and the ppt. obtained was ground in a mortar. The ppt. was again mixed with ether, pptd. by acetone and treated as before. This was repeated three times. The ppt. was then rubbed in a mortar with a large excess of water, and one-third volume of acetone added. The ppt. was reemulsified and repptd. three times. The final ppt. was dried by the addition of acetone and ether. The ether soln. was centrifuged, giving an impure ppt. of sphingomyelin, the ether layer decanted and acetone added. The resulting ppt. was redissolved in ether and repptd. with acetone. The ppt. was then dissolved in alc., allowed to stand to ppt. the cephalin, and filtered. The filtrate was evapd. under reduced pressure at 40° , the residue taken up with ether, and the phosphatide pptd. with acetone. The ppt. gave a clear soln. with ether and alc. B. HOROWITZ.

The diazo reactions of histidine and tyrosine. GINSABURO TOTANI. Cambridge. *Biochem. J.* 9, 385-92(1915).—By reducing the red diazo compounds of histidine and tyrosine, and then rendering the soln. alk., the tyrosine gives a rose red whereas the histidine yields a golden yellow color. *Method:* A few cc. of the soln. to be tested are made alkaline with an excess of Na_2CO_3 soln. A few cg. of the *freshly prepared* diazobenzenesulfonic acid are dissolved in a small quantity of Na_2CO_3 soln. The reagent and soln. are then mixed. Within three minutes the fluid assumes a dark red color if histidine or tyrosine be present. Enough concd. HCl is then added to make the soln. distinctly acid. The acid soln. is reduced by Zn dust, yielding a colorless soln. To a small portion of this, two volumes of NH_4OH (25%) are added.

B. HOROWITZ.

The use of radium emanation condensed in closed tubes in place of radioactive compounds, and the estimation (in millicuries of emanation decomposed) of the energy used up in radioactive applications in general. DEBIERNE AND REGAUD. *Compt. rend.* 161, 422-4(1915).—Attention is called to the advantages, in the biological application of Ra, of using Ra Em condensed in small closed tubes over the use of solid Ra preps. The former may be inclosed in a tube of any shape most applicable to the case for which it is to be used, and by using the Em danger of loss of the mother material during the application is avoided. It is suggested that the dosage of radioactivity applied should be expressed as millicuries of Ra Em decomposed during the application.

ERNEST D. CLARK.

A new culture medium for cholera diagnosis. C. LANGE. *Deut. med. Wochschr.* 41, 1119-20(1915).—The principle of the new medium is based on the fact that only very few bacteria encountered in the feces attack starch at high degrees of alkalinity. Agar is prepd. containing 40 cc. 10% Na_2CO_3 soln. in 1000 cc., after neutralization of agar to litmus. Six parts of this agar are mixed with one part of 5% starch soln. Rice starch is added to cold water and heated in the water bath. It is then sterilized by short treatment in the autoclave. The cholera bacilli grow abundantly on this agar, forming round translucent areas on the otherwise turbid medium. Cholera colonies have a very characteristic appearance.

S. AMBERG.

The supposed biochemical variation of the Bulgarian ferment. F. DUCHACEK. Paris. *Ann. inst. Pasteur* 29, 347-56(1915); cf. *C. A.* 9, 2920.—The organism of Bertrand and that of Effront act similarly when grown on media containing glucose, but in no case was the transformation of one into the other observed.

GEO. T. CALDWELL.

An improvement in the composition of lactose bile. T. W. MELIA. *Am. J. Pub. Health* 5, 1168-74(1915).—Five % dried ox-gall in the bile is better than 10%, as heretofore recommended. It gives a gas more rapidly and in greater amt. Positive tests appear in higher dilns. Attenuated *B. coli* are shown more readily; interference by other bacteria, especially streptococci, is less. In identifying *B. typhi* by this method it is better to omit the lactose and incubate longer; in the case of *B. coli* the lactose sometimes changes its character to non-acidifying; this sometimes interferes with the identification of *B. typhi*. Advantages with reference to clearness, foaming, etc., obtained by using the 5% bile, are pointed out.

J. GAUB.

The reducing enzyme of *Bacillus coli communis*. A. HARDEN AND S. S. ZILVA. Lister Inst., London. *Biochem. J.* 9, 379-84(1915).—*B. coli communis* (Escherich), when washed, will not reduce methylene blue. The addition of various reagents incapable in themselves of effecting reduction—such as the sodium salts of some of the fatty acids, the common sugars, some amino acids, albumin, globulin, Witte peptone, etc.—causes the bacilli to re-acquire reducing power. B. HOROWITZ.

Resistance to chemical agents of certain series of *Bacillus subtilis*. P. PORTER. *Compt. rend.* 161, 397-9(1915).—The pure cultures of the bacteria in question were sown on ordinary beef bouillon containing 5% of glycerol and the growths obtained were immersed in the various chemical agents whose action is to be studied. After contact, the liquid was poured off and immediately replaced with either sterile H_2O or 95% EtOH. The culture fragments were then aseptically transferred to new bouillon, incubated at 40° , and the time noted in which the culture develops. The periods of resistance to growth shown by various germicidal agents were as follows: 5% C_2H_5OH , more than 50 hrs.; 20% $HCHO$, more than 25 hrs.; tincture of I, o.1 strength, more than 24 but less than 48 hrs.; fixing liquid of Bouin, more than 13 but less than 24 hrs.; 65 or 95% EtOH, more than 14 months. Immersion in the following liquids was preceded by dehydration with abs. alc.: oil of cloves more than 4 hrs.; oil of turpentine or oil of cedar, more than 15 hrs.; $CHCl_3$, more than 14 months. L. W. RIGGS.

Some effects of selection on the production of alkaloids in belladonna. A. F. SWEERS. Bur. of Plant Ind., U. S. Dept. Agric., *Bull.* 306(1915).—First generation plants, grown from seed of cross-pollinated selected individuals, displayed the characteristic of the maternal plant with respect to alkaloid productivity; this was usually true at all stages of growth during a season, and also for at least 2 successive seasons. Close pollination of the parent plant exerted only a moderate influence on the transmission of this characteristic. Second generation plants from cross-pollination were grown in Virginia, South Carolina and Wisconsin; at all 3 places they displayed the relative alkaloid-producing tendencies which were evident in the original parent plant and the generation preceding. The yield of alkaloids varied with the locality, but no definite relationship could be traced between the amt. of atm. pptn. and sunshine and the % of alkaloids. Plants, grown from cuttings and examd. at 2 stages of their growth, showed a marked tendency to display the same characteristic with respect to alkaloid production, as the plants from which they were propagated and the original parents of these plants. Renal function as measured by the elimination of fluids, salt and nitrogen and the specific gravity of the urine. HERMAN O. MOSENTHAL. Johns Hopkins Hosp. *Arch. Intern. Med.* 16, 733-74(1915).—The nephritic test-meal of Hedinger and Schlager (*Deut. Arch. klin. Med.* 114, 120(1914)), slightly modified and elaborated by M., is considered to be a valuable test of renal function and of great value in the diagnosis of cardiac, renal and other conditions. The meal contains approx. 13.4 g. N, 0.5 g. NaCl and 1760 cc. of fluid with a considerable quantity of purine material in the form of meat, soup, tea and coffee. This meal is divided into 3 parts, taken at 8 A.M., 12 noon, and 5 P.M. The urine is collected in 2-hr. periods from 8 A.M. to 8 P.M. and then in one period from 8 P.M. to 8 A.M. Normal individuals yield urines whose sp. gr. varies 0.010 from the highest to the lowest; they yield a night urine whose vol. is 400 cc. or less and whose sp. gr. is 1.018 or more, and which contains at least 1% N. When kidney function becomes involved, the first signs are usually demonstrated in the night urine, one or all of the following changes being observed: increase in vol., decrease in sp. gr. and N concn. Severe functional inadequacy of the kidney is indicated by a markedly low and fixed sp. gr., a diminished output of NaCl and N, a tendency to total polyuria and a night urine showing increase in vol., low sp. gr. and low concn. of N. Such functional inadequacy is not confined to nephritis but is also found in pyelitis, hypertrophied prostate, marked anemia, pyelonephritis, polycystic kidney and diabetes insipidus. Prognosis and therapy depend upon the cause of the impairment and not upon its degree. In cardiac cases, with decompensation, the sp. gr. is fixed at about 1.020, the NaCl output is diminished, that of N is high and there is oliguria. As compensation is established, the compn. of the urine changes until when complete compensation has been established there is a tendency to a low, fixed sp. gr. and nocturnal polyuria for some time until the kidney resumes its normal activity. In combined chronic nephritis and cardiac decompensation, the urine shows the characteristics of both conditions, the degree to which the one or the other predominates depending upon the severity of the lesions in the two organs.

I. GREENWALD.

The resistance of the red blood cells to hypotonic salt solutions in the various

anemias, with observations on the resistance after arsenical treatment and after splenectomy. LEWIS WEBB HILL. Mass. Gen. Hosp. *Arch. Intern. Med.* 16, 809-17 (1915).—Washed corpuscles were treated with NaCl solns. of different concns. for 2 hrs. and the concns. in which hemolysis had begun and in which it had been completed were observed. The resistance of normal blood cells to hemolysis is const. The figures for pernicious anemia and secondary anemia are practically the same. In any given case the resistance may be high, low or normal. In general, initial hemolysis is likely to occur in a higher concn. of NaCl but to be complete in a lower concn. than is the case with normal blood. The hemoglobin content of the cell seems to bear no relation to its resistance. The previous administration of As increases the resistance of the red cells. Splenectomy lowers the limit of complete hemolysis but partial hemolysis may occur at a higher concn. than before the operation. A review of literature is included.

I. GREENWALD.

Clinical studies on the respiration. I. The effect of carbon dioxide in the inspired air on patients with cardiac disease. FRANCIS W. PRABODY. Peter Bent Brigham Hosp., Boston. *Arch. Intern. Med.* 16, 846-64 (1915).—In normal individuals, the total ventilation of the lungs is doubled when the concn. of the CO₂ in the inspired air is increased to between 4.2 and 5.4%. A similar result is obtained with patients with cardiac and cardiorenal disease, whose alveolar CO₂ tension indicates the absence of acidosis. If acidosis exists, such patients are much more susceptible to an increase of CO₂ in the air and ventilation may be doubled when the air contains only between 2 and 3% CO₂. It is suggested that, although probably not the sole factor causing the dyspnea in cardiac and cardiorenal disease, the acidosis may be an element of considerable importance. II. The acidosis of chronic nephritis. *Ibid* 955-66.—In chronic nephritis there is little or no acidosis unless the phenolsulfonephthalein output is diminished. The "alkali tolerance" is first affected. Generally only advanced cases show a diminution of the alveolar CO₂ tension and this may be normal even in severe cases. In the few cases in which acidosis is evident, it is readily relieved by alkali therapy.

I. GREENWALD.

The coagulation test for syphilis, as devised by Hirschfeld and Klinger. HAROLD N. COLE AND SAMUEL E.-K. CHIN. Western Reserve Univ. *Arch. Intern. Med.* 16, 880-9 (1915); cf. *C. A.* 9, 469.—The coagulation test carefully carried out is as specific as, and more delicate than, the Wassermann, in cases of treated, latent and cerebrospinal syphilis. After prolonged and effective treatment, syphilitic cases give negative results with the coagulation test. A few primary cases have given good results with the coagulation test while the Wassermann test was still negative. Detailed descriptions are given for the prepn. of the reagents and the performance of the test.

I. GREENWALD.

The relation of dentistry to neurology. CHRISTOPHER C. BELING. Newark, N. J. *Dental Cosmos* 57, 1360-5 (1915).—Of biochemical interest are the sections devoted to influence of occupations on the teeth, and to ductless glands. "Workers exposed to the effects of Hg and As are more prone to suffer from putrefactions of the gums which induce pyorrhea and oral sepsis." The Cu salts, to which workers in Cu are exposed, exert a prophylactic action with respect to caries and oral sepsis. Hypothyroidism gives rise to a deficiency of Ca salts or other chem. constituents of the teeth.

A. N. RICHARDS.

Clinical and experimental investigation of the relation of the active principle of Apocynum to the heart mechanism. ADOLF H. HECHT. Vienna. *Z. exp. Med.* 4, 264-58(1915).—Apocynum and cymarin produce on the heart effects similar to those produced by strophanthin. These substances are less active and also less poisonous. They lack any marked cumulative action. GEO. T. CALDWELL.

The effect of Erlenmeyer's bromide mixture and of codeine upon experimentally produced convulsions. H. JANUSCHKE AND M. MASSLOW. Vienna. *Z. exp. Med.* 4, 301-12(1915).—Erlenmeyer's mixt. injected intravenously in rabbits in very small doses produces convulsions and death. The quieting action of this mixt. is not quite identical with that of NaBr: (a) with subcutaneous injection the convulsion centers of camphor in the medulla are clearly protected, while the cocaine centers of the cerebrum are not; (b) with long-continued administration by mouth, the motor centers of the cerebral cortex and the medulla oblongata are protected, while the picrotoxin center of the spinal cord is not; (c) a retarding influence on the sensory neurone of the reflex arc and on the motor curve endings of the skeletal musculature is lacking with this mixt. just as with NaBr. The protection of the convulsion center of the medulla is quantitatively no greater than with NaBr. Codeine in animals protects against some of the convulsion-producing poisons investigated, but acts rather as a convulsant. GEO. T. CALDWELL.

The so-called sensitization of the vascular system toward epinephrine by cocaine. RICHARD FISCHEL. Prague. *Z. exp. Med.* 4, 562-78(1915).—Cocaine in extremely small doses (0.000001 g.) injected intravenously into rabbits increases the excitability for epinephrine during the perfusion of the vascular system by the latter. A cocaine-epinephrine mixt. (both substances being applied at the same time) produces the most marked effects. If the cocaine is applied before the epinephrine a much smaller vasoconstriction is obtained and cocaine administered in the relaxing phase produces no recognizable effect. GEO. T. CALDWELL.

The use of quinine in the treatment of experimental gaseous gangrene. The value of quinine hydrochloride as a general antiseptic. K. TAYLOR. Paris. *Lancet* 1915, II, 538-40.—*In vivo*, quinine was 70 times as effective as phenol in inhibiting the growth of the gas bacillus. In animals it reduced the mortality from 100% to 41%. Quinine does not damage healthy tissues in local injections of effective concn. It produced no symptoms of intoxication in the animals treated. GEO. T. CALDWELL.

The similarity and synergy of morphine and strychnine action. HUGH MCGURGAN AND E. L. ROSS. Chicago. *J. Pharmacol.* 7, 385-405(1915).—Oxidized morphine (by treatment with HNO_3) to a certain degree produces tetanus more quickly than unoxidized morphine after intraspinal injection in dogs and cats, or in the lymph of frogs. Oxidized codeine will also produce tetanus. Unoxidized codeine produces tetanus in frogs more quickly than morphine, but not in dogs. Oxidized morphine administered other than intraspinally does not produce convulsions in mammals. The strychnine-like action of morphine is apparently due to an oxidation product which is first produced and then destroyed in the body. Differences in the rate of oxidation will explain the varied reaction in different animals. P. J. HANLICK.

The synergism of morphine and the scopolamines. MAURICE I. SMITH. Ann Arbor. *J. Pharmacol.* 7, 407-21(1915).—Scopolamines are synergistic with morphine in the frog, both in combined sublethal as well as combined lethal doses. There is a synergistic action between scopolamine and morphine on the frog heart and in the respiratory centers. The toxicity of the scopolamine-morphine com-

bination in the mouse is increased with the relative increase of the scopolamine content of the combined dose. *l*-Scopolamine is more toxic to the mouse in combination with morphine than *d*-scopolamine. In other respects the 2 scopolamines are essentially alike in their relation to morphine.

P. J. HANZLIK.

The action of cocaine. M. KURODA. London. *J. Pharmacol.* 7, 423-39(1915).

—Cocaine was found to dilate the surviving vessels of frog and mammal, depress the heart (frog and mammalian), augment the intestinal and gastric peristalsis with small doses and depress with large, contract the non-pregnant uterus of dog, cat and rabbit and pregnant uterus of cat, augment bladder peristalsis, but had no effect on the salivary gland. With the exception of rabbit and dog non-pregnant and cat pregnant uterus, epinephrine in all cases produces the opposite effects. Cocaine first stimulates then depresses smooth muscle, whatever be the nature of the sympathetic control. Upon the basis of the results obtained it is suggested that the pupilo-dilatation produced by cocaine is due to a direct action on the muscle of the iris and not to stimulation of sympathetic endings. The effects of cocaine on smooth muscle are analogous to those on the other forms of protoplasm, inclusive of sensory organs.

P. J. HANZLIK.

The effect of caffeine upon the blood flow in normal human subjects. J. H. MEANS AND L. H. NEWBURGH. Boston. *J. Pharmacol.* 7, 449-65(1915).—The method of Krogh and Lindhard for the detn. of blood flow was used. The action of caffeine on the blood flow was studied in two subjects at rest, and in one during work. The drug produced an increase in total blood flow without a corresponding increase in O absorption, hence a decreased coeff. of utilization of O-carrying capacity of the blood; pulse rate remained unchanged, and consequently systolic output was increased. During work there was possibly an increase in pulse rate and consequently slight diminution in systolic output. It is suggested that during rest when the supply of blood to the right heart is "inadequate" caffeine increases the blood flow by increasing the venous supply through an action upon some mechanism outside the heart. When the supply becomes "adequate" or approaches adequacy, no such action is obtained.

P. J. HANZLIK.

Urine formation by the perfused kidney: Preliminary experiments on the action of caffeine. A. N. RICHARDS AND O. H. PLANT. Phila. *J. Pharmacol.* 7, 485-509 (1915).—Rabbit kidney was perfused *in situ* with hirudinized blood under conditions which permitted adjustment and measurement of the blood flow through the kidney, using the special app. constructed by Richards and Drinker (cf. *C. A.* 10, 345). When blood flow through the perfused kidney amounts to 28 cc. per minute, fluid similar in compn. to urine is obtained from the ureter. When the blood flow through the kidney is constant, rate of urine secretion is constant, and apparently independent of pressure changes in the renal circulation provided changes in pressure do not cause changes in vol. of blood flowing through it. Caffeine causes diuresis in the perfused kidney when the rate of blood flow through the organ remains constant. From this it is suggested that increased renal blood flow produced by caffeine is not essential in its diuretic action. Five % NaCl is diuretic when blood flow through the kidney is constant, but 0.9% NaCl in dosage used is perhaps not diuretic; phlorhizin causes both diuresis and glucosuria.

P. J. HANZLIK.

The response of the surviving uterus to morphine and scopolamine. HENRY G. BARBOUR AND MAT H. COPENHASER. *J. Pharmacol.* 7, 509-39(1915)—Morphine (0.002 to 0.1%) and scopolamine (0.001 to 0.06%) alone, and when mixed, produce an increase in tone of the isolated uterus (pregnant and nonpregnant cats and guinea pigs). Scopolamine as a uterine stimulant is 10 times as powerful as morphine. Very high concns. of both drugs produce uterine tetanus. No synergism or antagonism upon

the uterus could be demonstrated for these drugs. These results are contradictory to those of Kehrer (*Arch. f. Gynäkol.* 81, 160(1907)). P. J. HANZLIK.

The action of phenylethylamine on the heart. HENRY G. BARBOUR AND EDWARD N. FRANKEL. New Haven. *J. Pharmacol.* 7, 511-27(1915).—Phenylethylamine (1:10,000 to 1:500) produces a diminution in rate and amplitude of the frog heart; the effects are temporary. Perfusion of the isolated rabbit heart with small doses gives a constant increase in amplitude without change in rate; larger doses decrease both. These effects are accompanied by marked reduction in coronary flow, but after larger doses the flow is increased. The intact heart of the cat shows increase in amplitude and rate with large and small doses; large doses cause decrease. Blood pressure rises with increased cardiac activity, also when the heart action is unchanged. With decreased cardiac activity the blood pressure falls. The vagus mechanism is thought not to be concerned in these effects. Phenylethylamine is presumably a cardiac muscle poison, in small amts. being stimulant, and in large amts. depressant; in all doses it produces coronary vasoconstriction, but with large doses a secondary relaxation occurs. P. J. HANZLIK.

Morphine and scopolamine action upon the intact uterus. HENRY GRAY BARBOUR. New Haven. *J. Pharmacol.* 7, 547-55(1915).—The tone of cat uterus *in situ* is increased by morphine and scopolamine in the same way as with the isolated organ. This was true of decerebrate and anesthetized animals. Neither drug, however, produces profound changes in uterine activity. A mixture of the drugs (up to 0.02 g. each) produces little or no effect. The delay in labor produced by either or both of these drugs is ascribed to their cerebral action. P. J. HANZLIK.

The action of caffeine and of epinephrine upon the vagus nerve. HENRY G. BARBOUR AND SIMON B. KLEINER. New Haven. *J. Pharmacol.* 7, 541-5(1915).—Perfusion of the frog heart with caffeine and epinephrine markedly lessens the response to faradic stimulation of the vagus. The minimal adequate concn. of caffeine lies between 0.02 and 0.05%; of epinephrine between 0.0005 and 0.001%. A more complete recovery of vagus sensitivity occurs after caffeine than after epinephrine. The results obtained with epinephrine are interpreted in the nature of a real vagus depression; with caffeine they are in part due to increased irritability of heart muscle. P. J. H.

The urinary phenomena of coffee. WILLIAM A. PEARSON. Hahnemann Medical College, Phila. *J. Am. Inst. Homeopathy* 8, 507-12(1915).—The diuretic effect of caffeine was noted; no marked effects were produced on sp. gr. and amt. of total solids, urea, chlorides and phosphates of the urine. Increased elimination of uric acid was noted in subjects taking 2x, 10x, 12x and 200x. JOSEPH S. HEPBURN.

The physiological effects of the rare earths. C. RICHARD BOHM. *Chem. Ztg.* 39, 875-8, 895-7(1915).—A review of the investigations of the action of salts of Ce, Th, Zr and Di on animal and plant life, their antiseptic and bactericidal properties, radioactivity, and the suitability of some of the oxides as substitutes for Bi compds. in Röntgen ray diagnosis. J. H. MOORE.

The treatment of amebic dysentery. GEORGE C. LOW. *Brit. Med. J.* 1915, II, 714-6.—In the majority of cases, emetine hydrochloride given subcutaneously or intramuscularly eliminates *Entameba histolytica*. In a case in which *Lambia intestinalis* was accompanied by *Entameba histolytica* cysts, emetine hydrochloride was without effect, while β -naphthol diminished, but did not entirely destroy the parasites. A. H. RAHE.

Amyl nitrite in chloroform poisoning. J. S. GILMAN, *et al.* Richmond. *Southern Med. J.* 8, No. 10(1915); *J. Am. Med. Assoc.* 65, 1586.—The results indicate that in-

halations of amyl nitrite definitely increased the dose of CHCl_3 required to cause the death of animals.

L. W. RIGGS.

Adalin intoxication. A. NIEUWENHUIJSE. *Nederlandsch Tijdschrift Geneeskunde* Sept. 18, 1915; *J. Am. Med. Assoc.* 65, 1594.—In the case reported the symptoms were like those of veronal poisoning, unconsciousness persisting nearly 60 hrs. and being followed by recovery. The dose had been about 3 g.

L. W. RIGGS.

Case of stramonium poisoning. W. D. McNALLY. Chicago. *J. Am. Med. Assoc.* 65, 1640(1915).—McN. reports a fatal case of a boy, aged 7 years, who died 14 hrs. after eating about 100 seeds of the "thorn apple," *Datura stramonium*. Symptoms and necropsy findings are given.

L. W. RIGGS.

Pharmacology of bronchial asthma. D. E. JACKSON. St. Louis. *J. Lab. Clin. Med.* 1, 126-30(1915).—A discussion of the action of various drugs in relation to the question of whether or not there are two distinct forms of spasmodic bronchial asthma, the one of nervous, the other of muscular origin.

H. G. W.

Quantitative studies on the persistence of chemotherapeutic agents in the blood of men and animals. E. BORCKER. Koch Inst., Berlin. *Z. Immunität.* 24, 148-66 (1915).—After intravenous injection of salvarsan a considerable amt. can be demonstrated in the blood, after 1-2 hrs. in man, horse and guinea pig, and after 24 hrs. usually in rabbits. Ethylhydrocuprein leaves the blood more quickly, but in guinea pigs it persists 2 hrs.; it is fixed by the blood cells and again given off. Formaldehyde and "Rhodaform" disappear quickly from the blood, and the latter prepn. cannot be found in the bile of dogs or rabbits in effective amts. These expts. demonstrate not only the importance of a low degree of organotropy, but indicate perhaps the most useful method of administration and the cause of unequal action in different species.

H. G. W.

Further investigations on the action of chemotherapeutic agents in vitro. OSCAR SCHIRMANN. Koch Inst., Berlin. *Z. Immunität.* 24, 167-87(1915).—Salvarsan and optochin (ethylhydrocuprein) in bouillon or serum are both bactericidal and inhibitory for the organisms for which they are specific, but the inhibitory action is much more striking and more useful in orientation expts. Serum and blood of different species often show considerable differences in these expts. Doses that in animal expts. are recognized as curative seem to correspond to a concn. in the blood that is not only inhibitory but also bactericidal. Chicken cholera could not be cured by quinine, and a corresponding ineffectiveness was found in the *in vitro* expts.

H. G. W.

Vibricidal power of the bile of animals after administration of hexamethylene-tetramine and its compounds. E. D. W. GREIG. *Indian J. Medical Res.* 2, 907-25 (1915).—Urotropine, helmitole (anhydromethylene citrate of urotropine) and cystopurine (urotropine-sodium acetate) were studied. Helmitole appeared to be distinctly more toxic than the others. The bile of a rabbit which had received helmitole, showed definitely the presence of HCHO , even though the bile was alk. in reaction. The bactericidal power of the bile of animals after administration of helmitole and urotropine is well marked in respect to the cholera vibrio; the bile of the treated animals must remain in contact with the vibrios for some time to effect their complete destruction. Only helmitole exerts any bactericidal action on the cholera vibrio *in vitro*; the addition of bile does not influence this action.

α,β -Diantipyrylurea, its derivatives and physiological properties (GÖTTLIEB) 10.

DIXON, W. E.: *A Manual of Pharmacology.* 4th ed. London: E. Arnold, 467 pp. 15 s.

I. ZOÖLOGY.

R. A. GORTNER.

The salts required for the development of insects. JACQUES LOEB. Rockefeller Inst. *J. Biol. Chem.* 23, 431-4(1915).—Five generations of banana-flies were raised on an aq. soln. of glucose, sucrose, NH_4 tartrate, citric acid, K_2HPO_4 and MgSO_4 . In these flies muscular activity is apparently possible without any Na or Ca, or with only such traces as were present in the pure chemicals used. K, PO_4 , Mg and SO_4 are necessary. Recent investigations seem to show that bacteria may form carbohydrates from the CO_2 of the air without the intervention of light. If this be true, as highly developed an animal as the banana-fly might have been evolved before the existence of chlorophyll. I. GREENWALD.

Note on the reduction of oxyhemocyanin in the serum of *Limulus polyphemus* L. CARL L. ALABERG. U. S. Bur. of Fisheries, Woods Hole. *J. Biol. Chem.* 23, 495-503(1915).—The blood of *Limulus* becomes decolorized on standing, but the reaction is much more marked in old blood than in fresh. The color may be restored by shaking with air but then fades very rapidly. These facts do not agree with the assumption that the fading is due to the presence of enzymes, of auto-oxidizable substances, of cell-fragments, etc. The serum has no marked oxidizing action upon other substances. The fading is inhibited by antiseptics such as toluene and CHCl_3 . "It would appear, therefore, that the reduction on standing of oxyhemocyanin observed in the serum of *Limulus* is probably due neither to enzymes nor to the presence of auto-oxidizable substances, but to the action of microorganisms." I. GREENWALD.

12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

Report on heavy metals in foods. H. M. LOOMIS. *J. Assoc. Official Agr. Chem.* 1, 244-54(1915).—The work on the detn. of As in foods was limited to modifications of the Gutzzeit method. That proposed by C. R. Smith, details given, appears to be very good, but requires a little further study. The Seeker-Clayton gravimetric method, Potter's modification of Teed's method, and the later method using NaHSO_4 , were used in detg. Pb in baking powder and baking powder chemicals. Potter's, and the NaHSO_4 modifications of Teed's method, are given in full. With the Seeker method, 20 cc., instead of 10 cc. of 10% HCl as originally proposed, were recommended for the collaborative work. Further study on all methods is recommended. H. S. BAILEY.

Heavy metals in foods: tin. E. L. P. TREUTHARDT. *J. Assoc. Official Agr. Chem.* 1, 254-64(1915).—A study of digestion methods, using HNO_3 and H_2SO_4 , and of 6 different methods for the detn. of Sn. The methods are given in detail, together with the results obtained by 6 collaborators. The Baker volumetric method is the most satisfactory. The electrolytic method of Cushman and Wettengel does not recover all of the Sn. Until some new means is devised which will recover all of the Sn without digestion, it seems safest to use the acid digestion. The volumetric method of Alexander, Bloomberg and Lourie, and a modification by Bloomberg, look promising, but the work done with these is not sufficient to warrant any conclusions. H. S. B.

Report on fruits and fruit products. H. C. GORE. *J. Assoc. Official Agr. Chem.* 1, 480-5(1915).—During 1914 a general method for the detn. of malic acid applicable to fruit juices, jellies, sirups, and other fruit products probably including vinegars and wines, was established. The malic acid is sepd. as Ba malate from alc. soln. and is then dissolved in hot water. Aliquots of this soln. are treated by each of the following methods: (1) Prep. a soln. of uranyl acetate containing 33.996 g. of the pure crystd. salt per l. Mix 25 cc. of this soln. with 25 cc. of the Ba malate soln. which should be neutral or faintly acid. Keep in the dark for at least 5 hrs. or preferably overnight

and polarize in a 200 mm. tube at 20°. From the observed levo-rotation find the amt. of malic acid present by consulting the table attached. (2) Prep. a soln. of $(\text{NH}_4)_2\text{MoO}_4 \cdot 4\text{H}_2\text{O}$ containing 172.8 g. MoO_3 per l. and a soln. containing 300 g. acetic acid per l. Mix 20 cc. of the molybdate soln. with 25 cc. of the malate soln. in a 50 cc. flask. Make up to the mark with the AcOH soln. Polarize as above and find the amt. of malic acid corresponding to the observed dextro-rotation by consulting a second table.

H. R. SMITH.

The acid ester of lemon juice. L. WOLFRUM AND J. PINNOW. *Z. Nahr.-Genussm.* 30, 144-56(1915).—A lemon juice containing 8.59 g. per 100 cc. of EtOH was found by W. and P. to contain 1.3 g. per 100 cc. of an acid Et ester of citric acid, $(\text{C}_6\text{H}_5)_3\text{H}_3\text{C}_6\text{H}_7\text{O}_7$. The substance was isolated by extg. the dealcoholized juice in a continuous extractor with ether, evapg. the ether, dissolving the residue in water and again extg. with ether. Extn. of the residues obtained in this way was repeated 3 times, the acid ester being finally pptd. as the Ca salt from an aq. soln. of the last residue; this ppt. was then decomposed with H_2SO_4 and the pure ester extd. from the soln. by extn. in a continuous extractor with ether. The pure substance recrystd. from ether had a m. p. of 108.5-109.5°. It differs from citric acid in not forming insol. Ba or Sr salts and in being much less sensitive to the Denigès reaction. Owing to its greater soly. in ether it may be sepd. from citric acid by repeated extn. in a continuous extractor of the aq. soln. as above. Analysis of its Ca, Pb and Ag salts, all of which are difficultly sol., shows it to be a mono-Et ester, and because of its resistance to oxidation, with KMnO_4 , W. and P. believe it to have a symmetrical structure. It can be made by boiling an EtOH soln. of citric acid under a reflux condenser and sepg. from the free acid in the manner given above. The distribution coeff. for the acid ester in ether-water for ordinary concns. is about 11 at 15° and 13 at 27°. Because of its slow rate of sapon. with alkalis (detd. by W. and P.) it cannot be accurately detd. in solns. containing sugars owing to the formation at the same time of acid substances due to decompn. of the sugars. To det. it in lemon juice evap. 50 cc. to $\frac{1}{2}$ its vol. to remove EtOH, make up to 25 cc. with water and ext. for 4 hrs. by perforation with ether. Evap. the ether, take up the residue in water, and neutralize exactly with alkali. Then add a measured excess of standard alkali and distil. Det. EtOH in the distillate by sp. gr. and titrate the excess of alkali in the residue remaining in the distn. flask. The quantity of EtOH found as well as the amt. of alkali used for the sapon. represents the amt. of acid ester present.

A. F. SEEKER.

Report on flavoring extracts. A. E. PAUL. *J. Assoc. Official Agr. Chem.* 1, 498-506(1915).—Collaborative work during 1914 on the detn. of essential oil in flavoring exts. warranted the following recommendations: (1) That the saponification method of Hortvet and West for wintergreen ext. as modified by R. S. Hiltner (*Bur. Chem., Bull.* 152, 41) be adopted as provisional. (2) That the Hortvet and West method (*C. A.* 3, 1189) be made provisional for anise and nutmeg exts. (3) That the following modification of the Howard-Mitchell method be provisionally adopted for peppermint and spearmint exts. and also as an additional method for wintergreen ext. *Method:* Pipet 10 cc. into a Babcock milk bottle, add 1 cc. CS_2 , mix, add 25 cc. cold water, and 1 cc. concd. HCl, shake vigorously, centrifuge 6 min. and remove all but 3 or 4 cc. of the supernatant liquid. Apply suction and immerse the bottle in water at 70° for 3 min. shaking vigorously every 15 sec. Continue in the same manner for 45 sec. using a boiling water bath. Remove from the bath and shake while cooling. Fill the bottle to the neck with satd. salt soln., centrifuge 2 min. and read from the top of the meniscus. Multiply the reading by 2 to obtain the % oil by vol. H. R. S.

Relationship between alcohol-soluble solids and ether-soluble solids in standard ginger extracts. C. W. HARRISON AND A. L. SULLIVAN. *J. Assoc. Official Agr. Chem.*

1, 506-10(1915).—The high cost of alc. has led to the attempt to put out exts. of low alc. content. Ginger differs from most spices in that water and weak alc. ext. a larger amt. of solid matter from it than does 95% alc.; but these additional extractives add nothing to the value of the ext. since the aromatic principles of the root,—the essential oils and oleoresins—are almost insol. in dil. alc. and water. Street (Bur. Chem., *Bull.* 137, 76) found that practically all of the solids in high grade exts. are sol. in 95% alc. H. and S. found that nearly all of these solids are also sol. in ether and, since some of the adulterants of ginger ext., sugar, molasses, glycerol, caramel, etc., are more or less sol. in alc. and are practically insol. in ether, it was thought that the latter solvent would give a better index of the purity of the sample. Eleven samples of the ginger root representing the African, Cochin, and Jamaica varieties were analyzed, and from each of these samples 2 exts. were made according to the U. S. P. method—one using 95% alc. and the other 50% alc. Tables showing the analyses of the roots and exts. are given. The solids in ginger exts. made with 95% alc. are nearly all sol. in ether. The soly. of the solids in ether decreases the weaker the alc. ext., even though the amount of total solids increases. Solids from exts. prepd. with 25% alc. are practically insol. in ether. Solids from exts. made from weak alc. are more insol. in ether than in alc. The % solids sol. in ether conveys more information as to the strength of an ext. than does the % of alc.-sol. solids.

H. R. SMITH.

Report on separation of nitrogenous bodies (meat proteins). A. D. EMMETT. *J. Assoc. Official Agr. Chem.* 1, 267-79(1915).—For the detn. of total N the Kjeldahl-Gunning-Arnold method gave as good results as either the Kjeldahl or Gunning methods. The time of digestion for the K.-G.-A. method has little or no influence. The percentage values were as high for 1.5 hrs. as for 4 hrs. digestion. The provisional method (Bur. Chem., *Bull.* 107, rev., p. 108) and a proposed optional method (details given) were used for the detn. of insol. N. From the results obtained by the collaborators, it would seem that the range between extreme values is greater for the provisional than for the optional method, but the grand averages indicate little difference between the 2 methods. The optional method is probably preferable, as no ether extrn. is necessary, and it gives more accurate results for sol. N, and is no less accurate for insol. N. For the detn. of creatine and creatinine in meat products the Folin method is the best at present available. Results from 6 laboratories indicate that the errors in this method for creatine in a standard soln. average about 4%. It is recommended (1) that the K.-G.-A. method for total N in meat and beef extract be made official; (2) that the following method for detg. sol. and insol. N in meat be made optional: Exhaust 7 to 25 g. of sample with 330 cc. of cold H₂O. Make 11 successive extns.; 4 of 50 cc., 4 of 25 cc., and 3 of 10 cc. Dil. the entire ext. to 500 cc., and det. N in 50 cc. Deduct the % of N found from the % of total N, and multiply the difference by 6.25 to obtain insol. protein. (3) That the Folin method for creatine and creatinine in meat and beef ext. be made official.

H. S. BAILEY.

Report on inorganic phosphorus estimation in plant and animal substances. E. B. FORBES AND A. E. D. WUSSEW. *J. Assoc. Official Agr. Chem.* 1, 221-43(1915).—An investigation of methods of inorganic P estn. involving a comparison with animal substances, of the neutral Mo method of Emmett and Grindley, Siegfried and Singewald's BaCl₂, and Forbes' magnesia mixt. methods. On plant substances the acid-EtOH methods of Forbes and of Collison, for the sepn. of phytin and inorganic phosphate, were investigated. Estns. with and without the addition of known amts. of inorganic P were used as a basis for judging the reliability of the methods. In the work on plant substances attention was given to completeness of extrn. and the influence of phenol in the extractive reagent. The methods used in the prepn. of the flesh, blood, brain, muscle, and the other exts., as well as all analytical procedure, are given in detail. A large amt.

of analytical data is also tabulated. On vacuum-dried muscle all 3 methods give almost identical results. The BaCl_2 method is inapplicable in the presence of $(\text{NH}_4)_2\text{SO}_4$ and cannot be used on exts. of brain and blood prepd. with this reagent. The magnesia mixt. method has usually given satisfactory results on all animal substances; further work, however, is needed on the influence of heat in the prepn. of exts. The prepn. of blood samples for analysis should be further studied, as there is evidence that some cleavage of org. P takes place during the heating of the ext. With plant substances the Collison method, although more easily workable, and yielding more complete recovery of added P than Forbes' method, either does not give complete extn., or the reagent causes cleavage of org. P compds. so that it seems to be without promise. Forbes' method gives exts. which are slow in filtering, and enzymic cleavage consequently sets in. The results are higher the more prolonged the filtration. The addition of phenol prevents the cleavage and does not interfere with the pptn. of the $\text{Mg-NH}_4\text{PO}_4$. The presence of phenol gave lower results with alfalfa, brewers' grains, rice polish, gluten feed, and wheat, and higher with blue grass, timothy, and wheat bran. The use of phenol in the method seems desirable. H. S. BAILEY.

The estimation of glycerol in meat juices and extracts. F. C. COOK. *J. Assoc. Official Agr. Chem.* 1, 279-81 (1915).—As semi-solid and fluid meat exts. often contain added glycerol, cane sugar, alc., and foreign protein, there is need for a quant. method for detg. glycerol. After exptg. with C_6H_6 , CHCl_3 , EtOH , gasoline, CCl_4 , and acetone as glycerol solvents, the following acetone method was adopted: Weigh into a Pb dish containing 20 g. of ignited sand 2 g. of solid or 5 g. of liquid meat prepn., and after transferring the dish and its contents to a mortar mix thoroughly with more ignited sand and several g. of anhydrous Na_2SO_4 . Transfer the entire mixt. to a Soxhlet, the siphon arm of which is loosely plugged with cotton. Ext. with anhydrous acetone 10 hrs. Distil off the solvent carefully, using a vacuum pump to remove the last traces. Take up the glycerol in H_2O , add a little AgNO_3 ; make up to 100 cc., let stand overnight, and filter. Oxidize part of the filtrate with $\text{K}_2\text{Cr}_2\text{O}_7$ by the Hefner method. The results obtained on samples of meat and yeast exts. to which known amts. of glycerol had been added show a recovery of 92-100%. This method is also applicable to the detn. of glycerol in inking pads. H. S. BAILEY.

Report on feeds and feeding stuffs. W. J. JONES, JR. *J. Assoc. Official Agr. Chem.* 1, 289-314 (1915).—The effect of time of extn. and of moisture on the detn. of fat by the petr. ether method, and the effect of petr. ether from different sources, were studied by J., using 25 different cattle feeds. The official Et_2O and petr. ether methods were compared, as also the results obtained when using abs. Et_2O on dried and undried samples. Using Squibb's ether containing 3% of EtOH , 16 of the samples showed an increase in ext. of 0.03 to 2.99% over that obtained with anhydrous Et_2O free from EtOH ; in 1 sample there was no difference, and in 6 there was a decrease of 0.02 to 0.21%. The effect of the time of drying the exts. also was studied. The analytical results are all tabulated in detail, and from these the following conclusions are drawn: With rare exception the official (Et_2O) method gives higher exts. than the petr. ether method; instead of 3 hrs., 9 hrs. are required to get max. results with petr. ether; the presence of H_2O materially affects the amt. of ext. obtained with petr. ether; the extn. of the same material with petr. ethers from different sources does not give concordant results; the exts. with petr. ether must be dried at least 3 hrs. to secure const. wt.; the extn., with abs. Et_2O , of undried samples usually gives higher results than those obtained by the official method. It is recommended that the petr. ether method for detn. of fat in cottonseed products be not adopted. H. S. BAILEY.

Change in potatoes during drying. H. I. WATERMAN. *Chem. Weekblad* 12 924-7 (1915).—W. adds further proof to his previous discoveries concerning the change

of starch into sucrose during drying at low temp. He found that the Eigenheimer variety after drying at 40° showed an increase of sucrose of 1%, while the "Zeeuwache blauwe" variety showed an increase of 3%. J. T. FLOHIL.

Report on dairy products. E. M. BAILEY. *J. Assoc. Official Agr. Chem.* 1, 289 (1915).—In view of the distinct advantages of the CuSO_4 method over the provisional AcOH method for the prepn. of milk serum for examn. by the refractometer, it is recommended that it be studied for adoption as an optional method. H. S. BAILEY.

The freezing point of milk from sick cows. A. C. PLIESTER. *Chem. Weekblad* 12, 354-9(1915); cf. *C. A.* 8, 3602.—P. gives data proving that the f. p. of milk from sick cows is never higher than -0.54° . Milk of sick cows has either a normal or lower f. p. In many cases in milk of sick cows the lactose had decreased considerably but at the same time the Cl content had increased to such an amount, that the osmotic pressure and f. p. were quite normal. P. furthermore confirmed the statements of Hamburger, Dreser, Winter and Koeppe that the osmotic pressure and f. p. in the milk is practically the same as that of the blood serum of the same cow; he found f. p. milk -0.605° and f. p. blood serum of the same cow -0.601° . P. advises a combination of the f. p. detn. with detn. of lactose (rotatory power), detn. of Cl, detn. of sp. gr. of serum, detn. of refractive index of the serum and enzymic reaction for the examn. of milk and concludes that milk is adulterated with water when the f. p. is higher than -0.54° ; the enzymic test shows no sickness and the other detns. point to the addition of water. J. T. FLOHIL.

Freezing point determination in milk. N. SCHOORL. *Chem. Weekblad* 12, 220-2 (1915).—To obtain reliable results with the f. p. detn. in milk the following precautions are suggested: The temp. of the freezing mixt. should be equal throughout. The surface of the milk must be a few cm. lower than that of the freezing mixt. The inoculation with frozen milk is preferable to the inoculation with ice and should be done by simply dropping into the milk a capillary tube filled with milk, previously frozen in the freezing mixt. Every thermometer used for the f. p. detn. should be standardized, as not all thermometers are reliable especially on account of thermic changes in the glass. J. T. FLOHIL.

The examination of cheese. S. TIJMSRA. *Chem. Weekblad* 11, 902-9(1914).—*Sampling*: When the cheese is new and the salt not yet evenly distributed it is advisable to analyze a segment instead of a boring. *Fat detn.*: T. advises the use of van Gulik's modification of Gerber's method for the detn. of fat in milk. To obtain accurate results, care should be taken that the following procedure is carried out exactly: Dissolve 3 g. cheese with H_2SO_4 (sp. gr. 1.53) in Gerber's butyrometer, heat to 68° and shake vigorously; let stand for 1 hr., add 1 cc. of amyl alc., shake, fill the butyrometer with H_2SO_4 and stopper, shake again for 5 min., heat to 68° , and centrifuge for 5 min. (2000 revolutions per min.), or longer when smaller speed is used. The reading is made after heating for 5 min. The results obtained by means of this method were compared with those obtained by the Bondzynski-Ratzlaff method and it was found that 12 out of 15 analyses checked within 0.2%. *Detn. of the dry matter*: 5 g. of cheese are weighed into a tared dish containing 25 g. of fine dune sand and a stirring rod. Five cc. of alc. are added, the mixt. heated to 70° for 5 min., stirred and dried to const. wt., being weighed at 45 min. intervals. J. T. FLOHIL.

Desiccating milk. D. J. HAUSS. U. S., 1,163,339, Dec. 7. After condensing by evapn., milk is atomized into a chamber heated externally and a downward current of heated air and milk particles undergoing desiccation is maintained through the chamber; the milk powder produced is sepd. at the bottom of the chamber.

Preserving eggs. H. E. THORNBURGH. U. S., 1,163,873, Dec. 14. Eggs in the shell are heated to 43-55° for several hrs. to render their bacterial content inactive. The eggs are then broken and their contents are dried or frozen.

Vinegar. H. BOULARD. U. S., 1,164,063, Dec. 14. See C. A. 9, 1206.

Sterilizing and preserving grain. E. R. BARROW. U. S., 1,165,220, Dec. 21. Oats, rice or other grain with the hulls on is intimately mixed with about 5% its wt. of finely pulverized NaCl to sterilize and preserve it. Cf. C. A. 9, 227, 3372.

Temporarily preserving green peas between harvesting and canning. C. H. PLUMMER. U. S., 1,164,861, Dec. 21. The peas are spread in shallow trays and treated with cold CO₂ or other gases to skin-dry them and are cooled to a point at which fermentation does not readily take place.

Unfermented beverage. W. O. KAISER and G. F. STROEBEL. U. S., 1,164,193, Dec. 14. Cf. C. A. 9, 2563. A lautmash is made by infusing ground malt with H₂O and peptonizing. Then ground cereals such as rice or grits are mashed with H₂O containing 2% of the lautmash, peptonized for 25 min. at 36° and then boiled for 50 min. The remaining lautmash is treated with a small amt. of H₂SO₄, HCl, H₃PO₄ or maltase which serves as a catalyzer and is boiled to convert starch, dextrin and maltose into glucose and ppt. amides; the acid in the product is neutralized, the cereal mash liquor added to the residue of ground malt and the temp. raised to saccharify the starch of the cereal wort. The 2 liquors are mixed, boiled with yeast and then with hops, acetic, lactic and succinic acids added in small amt. with EtOAc and the product carbonated.

Unfermented beverage. W. O. KAISER and G. F. STROEBEL. U. S., 1,164,287, Dec. 14. A peptonized mash of ground malt and H₂O is mixed with a fresh cereal mash and the mixt. is heated to saccharify the starch. Additional mash of ground malt is added and the mixt. is heated to stop diastatic action. The residue of the ground malt mash is added to the mixt. and the temp. raised to saccharify the additional starch present, the wort is sepd. and boiled successively with hops and yeast, aged, filtered and carbonated.

"Soy-milk." L. J. MONAHAN and C. J. POPE. U. S., 1,165,199, Dec. 21. Soy beans, ground to a coarse powder, are emulsified with an equal amt. of lime-water at a temp. above 25°, with the addition of a small amt. of NaHCO₃, the emulsion is

cooked and the insol. matter is removed by filtration. Small amts. of NaCl and coconut oil may be added.

Cereal food. W. A. RULLMAN. U. S., 1,163,175, Dec. 7. Granular cereal, *e. g.*, germinated barley and wheat, containing about 75 parts nutritive substances and bran 4 is mixed with agar-agar 21 parts while moistened and dried to cause the agar-agar to adhere to the granules.

Impregnating meat with preserving compositions. A. R. BULLOCK. Ger., 285,270, Aug. 13, 1912. See Fr., 448,191 (C. A. 7, 2077).

Preserving fruit and grape juices, fruit pulp. A. MARGOLIUS. Ger., 285,089, Sept. 26, 1913. Instead of benzoic acid, the various chlorobenzoic acids or their alkali salts are employed as preservatives. *p*-Chlorobenzoic acid, in spite of its harmlessness, exceeds many times the preserving action of benzoic acid. *E. g.*, fermenting cider may be preserved indefinitely by the addition of 0.1% of the Na salt of the mixt. of chlorobenzoic acids obtained by chlorinating benzoic acid. The fermentation is at once inhibited. The filtrate taken after 30 mins. is permanently stable. Fresh fruit juices, such as raspberry juice, fruit pulp, or the like, can be preserved by the addition of 0.1% of the Na salt of *p*-chlorobenzoic acid so that they neither ferment nor mold, and the color of the fruit juice is not affected. To 100 liters fresh grape juice, 100 g. Na *p*-chlorobenzoate dissolved in 2.5 liters H₂O are used. The grape juice so treated will keep permanently.

Substitute for fruit marmalades. F. SAUER. Ger., 285,152, Sept. 1, 1912. Albuminous vegetable flour is subjected to the action of diastase, whereby it is saccharified, and then the mass is fermented with lactic acid ferment, and finally evapd. Preferably, after the action of the malt peptase on the dissolved albumin, the insol. albuminous substances sepd. from the wort are partly converted into albumoses, whereupon, after the usual neutralization of any acid present, both constituents are united. Glycerophosphoric acid or its salts may be employed in forming the albumoses. The initial material rich in albumin may consist of a mixt. of malt, potato, and vegetable albumin, especially malt albumin. *E. g.*, 15 kg. barley flour (without hulls) are mashed cold with 90 liters of H₂O, 30 liters of clear ext. are drawn off and the remaining mash is saccharified as completely as possible by the infusion process and boiling. After cooling to about 40° the mash is mixed with the cold ext. and so much H₂O is added that the ext. content of the mash is about 10%. With the employment, then, of malt peptase, together with the rizing infusion process, a high degree of saccharification is effected which corresponds to about 80% sugar to 20% dextrin. The undissolved proteins are then sepd. from the malt wort, and the wort itself is subjected to a pure lactic acid fermentation by yoghurt bacilli which are then killed, after sufficient acidification, by heat. During this time the undissolved proteins are mixed with five times their amt. of H₂O and 0.2% glycerophosphoric acid, and maintained at about 80° under a pressure of 2 atm. for 10 hrs. with occasional stirring. After relieving the pressure, the neutralization of the acid, the mixing with the wort, and the evapn. in vacuo, are effected.

An imperishable essence for preparing non-alcoholic beverages. H. LASSAG. Ger., 285,090. Aug. 12, 1913. A soln. containing lactic acid, obtained by the fermentation of a liquid containing milk sugar, such as whey, is concd. with prevention of caramelization or condensation in the heat, preferably by freezing out, to about 5% lactic acid content, and this concd. soln. is mixed with an amt. of invert sugar sufficient to ensure preservation. The high content of lactic acid admits of the addition of the large amt. of sugar required to preserve the product, without obtaining an insipid taste. The invert sugar required may be produced, to advantage, in the lactic

acid soln. itself, by adding cane sugar, after concn., and inverting this in the known manner by heating. The excessive sweet taste is thereby masked. *E. g.*, lactic acid bacteria are added to whey, and the liquid is allowed to ferment at 35-45°. A serum containing about 20% lactic acid is obtained, and filtered. This serum is concd. by freezing to about 5% lactic acid content, and then about 4 kg. cane sugar are added to 3 liters of the liquid. The lactic acid-containing sugar soln. is then heated to about 100°, when inversion is effected. After filtration the product is ready for use with H₂O. Flavors, etc., may be added.

14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW.

Determination of hardness of water by Blacher's method. P. A. MEERBURG. *Chem. Weekblad* 12, 920-4(1915).—Comparison was made between the different methods for detg. the hardness of water. It was found that Blacher's method (cf. *C. A.* 7, 1394, 1938) gives more accurate results and gives them more quickly than the soap methods. M. detd. the hardness of 237 samples of water, the CaO and MgO of which were also detd. It was found that 5% of the samples with hardness less than 10° (German degrees) showed an error of more than 1%; 10% of those with a hardness between 10° and 20°; 20% of those between 20° and 30°; and 15% of those between 30° and 40°.

J. T. FLOHN.

Instructions for the rapid analysis of drinking water during a campaign. Intended for use by the corps of field hospitals. ANON. *Ann. fals.* 8, 212-5(1915).—Simple methods for testing potable water for nitrites, NH₃, reduction of KMnO₄, reaction with AgNO₃, and degree of hardness.

H. S. BAILEY.

Toxicological analysis of drinking water. E. KOHN-ABREST. *Ann. fals.* 8, 207-11(1915).—Concise directions for the detection in water of Cl, SO₂, Br, organic Fe salts, As, Ni, Co, Ba, Pb, CN, alkaloids, and glucosides. These directions, and the reagents, and app. required for carrying them out, are intended for the analysts of an army in the field.

H. S. BAILEY.

Sterilization of drinking water with chlorine. F. DITTHORN. *Deut. med. Wochschr.* 41, 1127(1915).—By means of 0.2 g. of a new Ca(OCl)₂ prepn. in powder form containing about 75% active Cl, 1 l. of strongly infected water can be sterilized in 10 min. The Cl is removed in 1-2 min. by adding 0.4 g. "Ortizon" (a stable compound of carbamide and H₂O₂). The water is slightly turbid but need not be filtered. S. A.

Ultraviolet ray sterilization of water. F. A. DALLYN AND N. F. PARKINSON. *Ann. Rept. Ontario Bd. Health* 1914; *Can. Engr.* 29, 686-92(1915).—Ultraviolet rays should preferably be applied to water free from turbidity or filtered. Expts. are detailed on sewage-infected tap water. With turbidity 5 to 20 parts per million, bacterial removal was over 97%; with turbidity 20-50 p. p. m. bacterial removal was from 94 to 97%. 110 and 500 volt lamps were used. D. concludes ultraviolet rays afford protection against irregularities of filters, with freedom from taste or odor in case of overdose.

LANGDON PEARSE.

Multiple filtration plant at Accra, Gold Coast Colony. ANON. *Engineering* 100, 461-2(1915).—The water which is high in org. matter passes through 4 series of strainers which contain crushed rock graded from 1 in. diameter in the 1st to 1/4 in. in the 4th. After each straining the water passes over a double-fall cascade for aeration. It then flows through 5 pre-filters of coarse sand, 1.5 ft. deep, on 8 in. of fine gravel. After pre-filtration, the water passes through slow sand filters.

W. D. HATFIELD.

Mixture of graphite and caustic soda for preventing scale. ANON. *Elec. World* 66, 1375(1915).—A mixture of graphite and caustic soda in the proportion of 50 oz.

to 30 lb. has been found effective in preventing boiler scale in a plant in Brooklyn. The conclusions have been drawn from experience with two 264-h. p. Babcock & Wilcox boilers operating at 110 lbs. pressure. The boilers are treated alternately, the mixt. being fed gradually to one boiler, and during that time it is not blown down. The other unit, however, is blown off to 80 lbs. every morning. C. G. F.

Use of aluminium as anti-incrustator in steam boilers. I. POUGET. *Compt. rend.* 161, 135-6(1915).—It was noted that the incrustation ordinarily formed on the walls of a water bath fed with hard water could be prevented by previous treatment with Al paint. The preventative action of powdered Al was confirmed by a sample expt. in which the containing vessels were weighed. The possibility that metallic Al could be used to advantage in steam boilers is suggested. W. F. LANGKELIER.

Results from better feed water in Wisconsin station. H. G. D. NUTTING. *Elec. World* 66, 1256-8(1915).—The water-treating plant consists of a 30,000 gal. steel settling tank and a chem. proportioning and feeding device. Operation of the softener is automatic. The av. daily amt. of soda ash required to treat 65,000 gals. creek-water is 35 lbs. and of lime 125 lbs. Cost per 1000 gals. is \$0.0163. Diagrams of the app. are given, also tables showing operating conditions before and after treating the boiler-feed water and an analysis of the raw creek-water used. I. C. M.

Pollution of California water supply well by discharge from sewage wells. C. G. HYDE. *Eng. Contr.* 44, 340(1915).—Wells sunk into water-bearing strata to dispose of sewage may contaminate water for drinking purposes even 600 ft. away.

LANGDON PEARSE.

Water-typhoid suit lost (Circleville, Ohio). *Eng. News* 74, 631-2(1915).—A suit to recover \$15,000 damages for a death from typhoid fever alleged to have been caused by polluted water due to a faulty check valve between a mill supply and a private water company supply was decided in favor of the company. The evidence showed the pollution of the water was common knowledge.

LANGDON PEARSE.

A septic tank decision. *Eng. News* 74, 667(1915).—The U. S. District Court has decided that the Cameron, Commin and Martin U. S. Pat. No. 634,423 expires on Oct. 3, 1916, in a suit against Winchester, Ky., for infringement by an Imhoff tank. Also in *Mun. Eng.* 49, 217(1915).

LANGDON PEARSE.

Garbage-reduction plant not a nuisance. *Public Health Reports* 30, 3473, 3507-11 (1915).—In *Toledo Disposal Co. vs. State*, 106 N. E. Rep. 6, the Supreme Court of Ohio held that a plant constructed and operated for the benefit of the public, and by legislative authority, could not be prosecuted as a public nuisance. Damages might be recovered.

LANGDON PEARSE.

Recent results of experiments on the purification of sewage by aeration in the presence of activated sludge, at the University of Illinois. EDWARD BARTOW AND F. W. MOHLMAN. *J. Ind. Eng. Chem.* 8, 15(1916); *Eng. Contr.* 44, 433-4(1915); *Eng. News* 74, 1096-7(1915); cf. *C. A.* 9, 1521.—A test plant of 4 tanks, each 3 ft. 2 in. square by 8 ft. 5 in. deep has been operated on domestic sewage, on the fill and draw plans. The sludge was accumulated on a 6-hr. cycle. Results show that 1 sq. ft. filtros in 10 sq. ft. tank area is not sufficient but 3 in 10 gives best results. About 1 cu. ft. air per gal. of sewage was used, but more was required on strong sewage. The free NH_3 and presence of nitrates were used as indicators. LANGDON PEARSE.

Rochester sewage disposal plant. ANON. *Mun. J.* 39, 915-6(1915).—The cost of Riensch-Wurl screens, grit chambers, and Imhoff tanks is about \$339,000.

LANGDON PEARSE.

New sewage disposal works at Wanstead. ANON. *Engineering* 100, 414-6 (1915).—Extensions of the old works comprize detritus-tanks with mechanical screens,

subdivision of old septic tank, new Dortmund tank, and percolating filters, storm-water tanks, sludge-pumping plant and sludge beds.

W. D. HATFIELD.

Changing sewage tanks to Imhoff type at Columbus, O. ANON. *Eng. Record* 72, 701-2(1915).—The conversion of the sedimentation tanks to Imhoff tanks is being done without shutting down the sewage disposal plant completely. One-half of the tanks are under reconstruction while the other half are in operation. Construction features are detailed.

FRANK BACHMANN.

Operating results of the Palo Alto refuse incinerator. *Eng. News* 74, 1125(1915).—An incinerator of a daily capacity of 30 tons of mixed refuse, treated 1872 tons in year ending June 30, 1915, at a cost of \$3117.81.

LANGDON PEARSE.

Garbage disposal in Dayton. J. E. BARLOW. *Mun. J.* 39, 913-5(1915).—Temporarily the garbage was buried. A reduction plant is under construction to use the cooking, pressing, drying and percolating system, with 125 tons' daily capacity. The cost is about \$440 per ton capacity.

LANGDON PEARSE.

Ozone for ventilation. S. T. POWELL. *Met. Chem. Eng.* 13, 975-7(1915).—Temp. and humidity have very little effect upon ozone production while the air velocity through the tubes has a direct bearing. High concns. acting for long periods have great germicidal action, efficiency being reduced with reduction of concn. Oxidizable odors may be completely removed. No detrimental effect of ozone on health was noticed.

W. D. HATFIELD.

Rapid method for detecting mineral poisons in water (FLEURY) 7. Activated, sludge as a fertilizer (BARTOW) 15.

FRANTZ, G.: *Dampfkesselschäden, deren Ursachen und möglichste Verhütung.* Kattowitz: Gebr. Bohm. 179 ss. 2.50 M.

Water-filter. A. L. GAMMAGE. U. S., 1,163,334, Dec. 7.

Apparatus for purifying water electrolytically. H. CLARK. U. S., 1,163,321, Dec. 7.

Apparatus for sedimentation and purification of sewage. T. J. BELFRANCI. U. S., 1,163,058, Dec. 7.

Incineration of garbage or other waste material. R. W. AMOS. U. S., 1,165,368, Dec. 21. Lime is mixed with garbage and it is heated to drive off vapors. The lighter vapors are led through a bed of lime and refuse nitrate and the heavier vapors are condensed and tapped off, without passing through the bed, to recover the alc. from them. The residue is mixed with S, lime and nitrate and burned.

Electrolysis of sewage. C. P. LANDRETH. *Brit.*, 18,564, Aug. 11, 1914. Sewage, effluents from tanneries or slaughter-houses, and other putrescible liquids to be electrolyzed, are treated with a hydroxide, as of lime, soda, or potash, in sufficient quantity to ensure alkalinity after the electrolysis. This alkalinity should be at least great enough to be indicated by phenolphthalein. Parallel electrode plates of C or Fe or other metal may be used. Fe electrodes are not attacked provided that sufficient alkali is present; the amt. of alkali required for this purpose increases with the c. d. High c. d. may, however, be used, so that hydroxide acting as a precipitant is formed from the anodes. The alkali, preferably milk of lime, is pumped or run from a tank into a preliminary settling-tank or a pipe through which the liquid to be treated passes

to the electrolytic vat; or the alkali may be run directly into this vat by a pipe opening above the bottom set of electrodes. In the last case, the lowest electrodes may be of C and serve for preliminary electrolysis to produce nascent O or hypochlorites, chlorides being added if required.

15. SOILS AND FERTILIZERS.

R. O. E. DAVIS.

The amino acid nitrogen of soil. R. S. POTTER AND R. S. SNYDER. *J. Ind. Eng. Chem.* 7, 1049-53(1915).—The work of Chardet (*C. A.* 9, 2683) who used the Soerensen method and found 49 to 68% of the soil N to be amino acid N was not confirmed. No amino acid N was found in dil. acid. ext. of soils, and none could be recovered when added by using dil. acid, but by extg. with dil. alkali all was recovered. Soils examd. were found to contain from 0.151 to 0.21% total N, 7.95 to 23.1 p. p. m. total amino acid N, 5.45 to 14.7 p. p. m. free amino acid and 30.9 to 31.5 p. p. m. total peptide. Amino acid did not accumulate in a limed and unlimed acid soil, nor in a manured soil in pots. Amino acid N was present in the soil in less amounts than $\text{NH}_4\text{-N}$. In the manured soil the amt. of NO_3 decreased at first, but it increased after 4 to 6 weeks. J. J. SKINNER.

The presence of proteoses and peptones in soils. E. H. WALTERS. *J. Ind. Eng. Chem.* 7, 860-3(1915).—Working with a sandy loam soil from Va., W. obtained, with an alkali and a H_2O ext., solns. which gave reactions with certain reagents which show that they contain a mixt. of the various proteoses and peptones resulting from the hydrolysis of proteins and that they exist and persist in the soil as such for a considerable period. An attempt to make further sepn. was not practical. The expts. indicate that proteins undergo hydrolytic decompns. in the soil in much the same way as on digestion by enzymes, acids, or alkalies in the laboratory. J. J. SKINNER.

Effect of vanillin as a soil constituent. J. J. SKINNER. *Plant World* 18, 321-30 (1915).—Cow peas, string beans and garden peas grown in the field on a clay loam soil at Arlington, Va., were checked in growth by vanillin applied to the soil in amts. of 284 lbs. per acre. With cow peas there was a reduction of 33% of green vines and 39% of cured hay. The garden peas were reduced 30% in vines and 20% in marketable peas. String beans were reduced 17% in vines and 69% in beans. Six months after vanillin was applied the soils were chemically examd., and vanillin was still found to be present. The soil used in pots after this lapse of time was found to be harmful to plants. The effect of vanillin on wheat plants grown in pots on 3 soils each having different properties and different geological origin was found to be different. On an unfertile sandy soil and a sandy loam, 400 to 500 p. p. m. vanillin reduced growth considerably, while on a rich productive loam, having good oxidizing power, the substance had no effect. J. J. SKINNER.

Petrography of some North Carolina soils and its relation to their fertilizer requirements. J. K. PLUMMER. N. C. Agr. Exp. Sta. *J. Agr. Research* 5, 569-82 (1915).—Very complete mineralogical analyses are given and ably discussed, and the following conclusions are drawn: Wide variations in mineralogical compn. are found between the soils of the Appalachian Mountains, Piedmont Plateau, and Atlantic Coastal Plain. There is unquestionably a greater supply of minerals which carry the inorg. plant-food constituents in the Mountain soils than are found in either the Piedmont Plateau or the Coastal Plain. Though many of the former soils are derived from the same rocks as those of the Piedmont province, the forces of erosion among the mountain soils cause them to contain minerals more nearly the same as the parent rocks than are found elsewhere. Definite information is required on the behavior

of the various soil-forming minerals to the forces of weathering before positive conclusions can be drawn on the availability of the plant food carried by the different minerals. Field results with the cotton plant indicate that there are some relationships existing between the mineral component of the soil and the requirements of this plant for the 3 inorganic fertilizer constituents, P_2O_5 , K_2O , and CaO . In addition to the above summarized results, this article is particularly valuable in its suggestiveness as to future lines of work and for its indication of present possibilities.

W. H. FRY.

The adsorption of potassium and phosphate ions by typical soils of the Connecticut Valley. R. H. BOGUE. *J. Phys. Chem.* 19, 665-95(1915).—The adsorptive capacities for K and P of 4 typical soils of the Connecticut valley were studied. The K content of the percolate from a sandy soil is quickly brought down to a concn. which is practically const., while with a sandy loam, a silt loam and a clay loam much more H_2O was required to pass through before this const. was reached. The same general tendency exists with P. The sandy soil reaches its state of satn. with respect to its K content in the shortest time and the clay soil takes the longest. The adsorption of P takes place much more slowly, the general tendency being the same. This study substantiates the results of former investigators in showing that when soils are subjected to the leaching action of H_2O the concn. of K and P in the soil ext. approaches a const. which appears to be fixed and definite for a given soil. Subjected to the action of sol. K and P salts, the concn. of these salts in the soil ext. is at first not materially increased, but as adsorption proceeds it becomes weaker and a point is finally reached where the amt. of sol. salts in the soil ext. is nearly equiv. to the amt. applied. The results substantiate the theory that the concn. of salts in the soil soln. is very largely dependent on the specific adsorptive capacity of the individual soil; they tend to disprove the theory that the compn. of the soil H_2O is detd. primarily by the chem. compn. of the soil, to prove this quality to be dependent on the mechanical texture of the individual soil.

J. J. SKINNER.

Phosphate rock and methods proposed for its utilization as a fertilizer. W. H. WAGGAMAN AND W. H. FRY. U. S. Dept. Agr., *Bull.* 312(1915).—The phosphate deposits of the United States are described, giving the extent and location of the beds and the character and quality of the deposits. Processes and methods are described of treating phosphate rock for producing phosphoric acid and phosphatic fertilizers by the use of heat, acids, alkalis or alkaline earths, also those used in the iron and steel industry, for volatilizing P or P_2O_5 , for production of two or more fertilizing elements, for producing available phosphate by electrolysis, for enriching phosphates, and for mechanically treating the phosphates. An appendix contains a classified tabular list of patented processes relating to treatment of phosphates.

R. O. E. D.

Fertilizer value of activated sludge. EDWARD BARTOW AND W. D. HATFIELD. *J. Ind. Eng. Chem.* 8, 17-20(1916); *Eng. Contr.* 44, 434-6(1915).—Pot studies and gardening expts. show that the N in activated sludge is in a very available form and that this sludge is valuable as a fertilizer, being comparable with dried blood.

LANGDON PRARSE.

The importance of fineness of subdivision to the utility of crushed limestone as a soil amendment. WALTER THOMAS AND WILLIAM FREAR. *J. Ind. Eng. Chem.* 7, 1041-2(1915).—Preliminary pot expts. with clover are described. Taking into consideration the cost of effecting the highest pulverization, and the fact that stone of $1/40$ to $1/60$ inch in fineness produced only about $2/3$ the effect secured with stone finer than $1/100$ inch, while stone of $1/60$ to $1/80$ inch caused more than $3/4$ of the effect secured from the finest stone, it is judged that compact limestone of high purity should be crushed to a fineness of not less than $1/60$ inch, to fit it for economical use as a soil amendment.

W. H. FRY.

The lime : magnesia ratio in soil amendments. W. THOMAS AND W. FREAR. *J. Ind. Eng. Chem.* 7, 1042-4(1915).—Experimenting with clover grown in an acid soil in paraffin pots it is shown that highly calcareous dressings were more beneficial than highly magnesian dressings. Yields from the hydrate applications exceed those from the corresponding carbonate applications. Dolomite was beneficial, but less so than the corresponding dressings of calcite and magnesite. From dolomite the plants took up less ash for each unit of dry matter increase than did those receiving the other dressings. From low Ca dressings the plants took proportionally more Mg than from high Ca dressings, and more Mg than Ca from the hydrate as compared with the carbonate dressings.

J. J. SKINNER.

Kalusz kainite. W. KOLSKI. *Wiener Landw. Ztg.* 65, 422(1915).—The deposits consist of 2 rich strata 5 m. thick, which contain about 60% of pure kainite, clay and NaCl being the chief contaminants. The material contains K 9-11, Na 8-20, Cl about 29 and SO₄ about 17.5%. On account of its lower Cl content the Kalusz kainite is superior to that found at Stassfurt and is shown experimentally to produce greater yields.

C. F. MILLER.

The effect of fertilizers on the growth of pineapples. CARLTON C. JAMES. *Forester Agriculturist (Hawaii)* 1911 (reprint).—Superphosphate, reverted phosphate, and steamed bonemeal showed good results when applied to pineapple plants; the first gave better results when applied together with lime. N is not the dominant element in pineapple fertilizing. Of the 3 forms of N studied, NaNO₃ was the least productive of good results. There was not much choice between (NH₄)₂SO₄ and steamed hoofmeal. Fertilized soil tends to bring the fruit to maturity from 2 to 4 weeks earlier than the unfertilized.

ODEN, S.: Eine neue Methode zur mechanischen Bodenanalyse. Berlin: Verlag für Fachliteratur. 55 ss. 3 M.

SMETHAM, A.: Potash: Its Distribution, Sources, and Agricultural Value.

Fertilizer. J. H. CONNOR. U. S., 1,163,130, Dec. 7. Blast furnace slag containing Ca and Mg salts is mixed with 3-30% of Na₂CO₃, lime and phosphate rock all in fine condition and the mixt. is calcined at a temp. of about 925-1650° to render a portion of the phosphates citrate-sol. and a portion H₂O-sol.

Phosphate fertilizer. S. B. NEWBERRY and H. N. BARRETT. U. S., 1,162,802, Dec. 7. Pulverized natural Ca phosphate is mixed with sufficient Na₂SO₄, NaOH, KOH or other alkali metal compd. to yield a mixt. which on calcination will contain 5-12% total alkali metal oxide and the mixt. is heated in the form of porous masses to 1100-1500° in a rapid current of hot gases to expel volatilizable products such as SO₂ together with part of the alkali compds. formed. The phosphate is rendered citrate-sol.

Phosphate fertilizers. S. B. NEWBERRY and H. N. BARRETT. U. S., 1,162,944, Dec. 7. Pulverized natural Ca phosphate is mixed with H₂O and with about 10% its wt. of Na₂SO₄. The mixt. is dried in such a way as to give it a porous cellular form and is then calcined at a temp. of 1100-1400° in a rapid current of hot gases to render the phosphate citrate-sol. and volatilize a portion of the alkali compds. Cf. C. A. 10, 246.

Fertilizers. BADISCHE. Brit., 18,299, Aug. 7, 1914. Urea nitrate is used as a fertilizer for tobacco and other plants.

16. **FERMENTED AND DISTILLED LIQUORS.**

ROBERT WAHL.

Investigation of the turbidity in brandy. DANIEL. *Chem. Ztg.* 39, 928(1915).—The turbidity in rum, cognac, etc., is due to Al, Fe, and Mg salts in the H₂O used. Ca salts are harmless. It may also be caused by excessive acidity in the essences used. D. recommends softening the H₂O with Na₂CO₃ and settling cold. To test the essences, add to soft H₂O in a test tube enough coloring to give a slight brown, then a few drops of alc., then 2 or 3 drops of the essence. No turbidity should appear in 24 hrs. The coloring is tested by coloring soft H₂O a slight brown and adding a few drops of a dil. soln. of tannic acid. No turbidity should appear.

J. H. MOORE.

Acid ratio: A new method for determining the proteolytic strength of germinated grain in technical analysis. C. A. NOWAK. *J. Ind. Eng. Chem.* 7, 858-9(1915).—N. gives a modification of the Soerensen HCHO method devised by him which is especially suitable for technical work. By dividing the value of the amino acid titration by the value (in cc.) of the natural acidity he obtains a ratio which he designates as the *acid ratio* and considers an entirely new factor in malt valuation. The method can be used to advantage in detg. whether a certain malt has been prepd. from a specific type of barley or whether it represents a mix. Aside from its great simplicity it has the further advantage that one single detn. suffices for the estn. of both the preformed amino acids present in the malt and the proteolytic strength.

C. A. NOWAK.

Beer. C. RACH. U. S., 1,163,453, Dec. 7. Beer wort is prepd. from 2 or more mashies (formed of raw grain and malt), one of which contains considerably less H₂O and more malt than the others and in which the diastatic action has been stopped before much maltose is formed and from which the wort has been extd. in concd. form by filter-pressing. The different worts are mixed, boiled with hops, fermented and ripened.

Beer. C. RACH. U. S., 1,163,454, Dec. 7. A fermented beer rich in sol. albuminoids and peptones prepd. from a mash containing at least 50% of malt and a krausen-wort rich in dextrins but poor in albuminoids and peptones are mixed and ripened together.

Carbonating and delivering beer. W. FINCH, S. W. PARKHURST and T. S. MURRAY. Brit., 18,006, July 30, 1914. In carbonating and delivering beer, etc., at a bar, the beer is forced by a pump through a non-return valve into a vessel containing CO₂ under slight pressure. The gas is compressed by the liquid and serves to discharge the liquid through a tap.

17. **PHARMACEUTICAL CHEMISTRY.**

M. I. WILBERT.

Stability of the infusion of digitalis. R. A. HATCHER and CARY EGGLESTON. New York. *J. Am. Med. Assoc.* 65, 1902-4(1915); cf. C. A. 7, 2651.—Alc. and aq. infusions of digitalis, when kept in the ice box or in an incubator at 37° for 28 days, showed activity as compared with the fresh infusion as follows: alc. infusion in ice box 96, in incubator 78; aq. infusion in ice box 80, in incubator 67. Samples were prepd. and allowed to stand under various conditions represented by careless dispensing and keeping. It was found that the infusion of digitalis is fairly stable, no important change taking place within one week. Addition of alc. is unnecessary. Old and even moldy leaves or infusions retained 50% of their activity for 4 months. The infusion has qualitatively the same action as the tincture, but the latter is recommended as being less variable in its activity.

L. W. RIGGS.

Adulteration of saffron by carthamus. G. VICARI. Lugano. *Mitt. Lebens. Hyg.* 6, 195-7(1915).—The saffron powder to be examd. is carefully spread over a glass slide by a glass rod in a thin coating without lumps. A drop of sulfophosphomolybdic reagent (60 cc. concd. H_2SO_4 to 40 cc. 10% Na phosphomolybdate) is allowed to fall upon the prepn., then the powder is well mixed and wetted with the reagent, giving to the whole a slightly greenish blue color. After a minute of rest, it is covered with a cover glass which is gently pressed down with a piece of filter-paper to remove the excess of reagent. Under a microscope of 50 diam. magnification, the particles of carthamus are detected by their reddish color, in the midst of the blue particles of saffron. A magnification of 100 diam. suffices for observation of the structure and behavior of the different elements of the powder with the reagent. If the particles of saffron are somewhat voluminous, or if the prepn. of the powder for the microscope is not properly done, the coloration may be masked. A certain indication of the presence of carthamus is furnished by observation under the microscope (100 diam. magnification) of the pollenaceous particles. These, as with phanerogams in general, are composed of 2 membranes, the outer or Exina being hard, resistant and granulated exteriorly, while the inner or Intina is soft and delicate. The Intina is filled with a relatively dense, hyaline, protoplasmic liquid. The Exina is pierced with 3 openings arranged symmetrically, through which the Intina issues, forming 3 typical protuberances. Under the microscope and in presence of the reagent, the Exina becomes colored brown, while the protuberances of the Intina gradually elongate, turn a bright greenish blue, and at last take on sack-like formations, on account of the endosmosis of the reagent through the membrane increasing the tension of the internal protoplasmic substance. In time the reagent attacks the Exina also, exposing to view its structure, thickness and granulation. Sometimes the complete Intina will break intact, through the weakening Exina. The pollenaceous particles of saffron under the action of the reagent merely color blue, without any other modification or swelling. Small traces of carthamus should not be looked upon as an adulteration, but rather as an unavoidable impurity. S. LEVY.

Solidifying and melting point of anethole. R. MELDRUM. *Chem. News* 112, 259-60(1915).—By the thermometer bulb method 15.7° was obtained as the m. p. of anethole. By the opacity method 17° was obtained as the mean of 10 detns. The difference is probably due to the larger amts. of substance used in the second method, thus making it more difficult to obtain a sharp m. p. The solidification point was detd. by 3 methods: (1) by stirring in an air jacket, (2) by stirring in a cold water jacket, and (3) by melting at 17° until about 2% remained unmelted, and then stirring in an air jacket until solidification commenced. The results of 22 detns. fell between 14.5 and 15.7° . It was observed that melting above the m. p. induced supercooling, with low solidifying points, while melting at the m. p. yielded high solidifying points. Anethole kept in stoppered bottles, exposed to the light for 5 months, gave a solidification point of 5.5° ; this low value is probably due to the absorption of O. R. L. SIBLEY.

Thiophysem. KRÖNIG. *Boll. chim. farm.* 54, 5(1915).—This prepn. is an iodated compd. the compn. of which corresponds to the addition of allylsulfourea and EtI; it contains 46.5% I and m. $69-71^\circ$.
H. S. PAINE.

Hemostatic gelatin. PONCHET AND TRIOLLET. Verona. *Boll. chim. farm.* 54, 8(1915).—Contrary to the opinion in some quarters gelatin does not lose its hemostatic action upon solidifying after being heated to 120° in aq. soln. The following procedure is recommended: Dissolve 8 g. NaCl in 1000 g. H_2O by heating and add 100 g. gelatin. After cooling add the whites of 3 eggs and stir thoroughly; keep the liquid in an autoclave for $\frac{1}{2}$ hr. at 120° . Filter through paper and add 0.002 g. K tellurite per 100 cc. to the filtrate; pour this liquid into 1 cc. vials and sterilize in an autoclave for a few

mins. at 110° in the usual manner. Keep the vials for 10 days before using in order to ascertain if any flora develop. Gelatin thus prepd. remains clear and active.

H. S. PAINE.

Hexaiodine. ANON. *Boll. chim. farm.* 54, 135(1915).—This prepn. is the monohydriodide of hexamethylenetetramine; it occurs as a white, inodorous, cryst. powder, m. 170–1°, of slightly saline taste, very sol. in H₂O and almost insol. in the common org. solvents; it contains 47.4% I. It is exceedingly well tolerated even in large doses and does not produce iodism; the prepn. causes increase in appetite in many cases and is indicated in all cases in which iodides are prescribed. The compd. is prepd. commercially as a soln. and in the form of tablets; it may be administered hypodermically or by mouth.

H. S. PAINE.

A disinfecting and deodorizing liquid. MAURICE FRANÇOIS. *J. pharm. chim.* 12, 220–4(1915).—"Perolin" is a pale yellow, clear liquid, forming an aromatic emulsion with H₂O. Its compn. is approx. dry K soap 15 g., essences 56 g., EtOH 18 g., HCHO 4.5 g. F. gives the following compn. of the imitation prepd. by him: K soap (50% H₂O) from vegetaline (*C. A.* 9, 3328) 50 g.; EtOH of 96% 50 g.; essence of lemon 25 g., of bergamot 5 g., of spike 25 g., of thyme 10 g., of verbena citronella 30 g., of rosemary 5 g.; formol 1 g. to 10 g. A mixt. of 25 cc. of this liquid with 500 cc. of H₂O is used in form of a spray.

S. WALDBOTT.

Absorbability of potassium iodide by the skin in different ointment bases. K. BARTENBACH. *Berl. Tier. Wochschr.; Vet. Rec.* July 17, 1915; *Pharm. J.* 95, 107 (1915).—Tests with lard, paraffin and lanolin as ointment bases for KI, applied to the skin of the horse, dog, ox, sheep and rabbit, show that the intact skin of these animals is permeable to KI in combination with the bases named. Lard favors the passage of KI most; with lanolin very large amts. of KI were required to obtain a positive I test in the urine. With either of the bases, the test appears after an av. period of 2 hrs. With the doses used, the period during which the iodide continued being excreted in the urine, never exceeded 24 hrs.

S. WALDBOTT.

Composition and pharmacological action of spiritus aetheris nitrosi. C. A. MARSHALL AND E. GILCHRIST. *Brit. Med. J.* July, 1915, 125; *Pharm. J.* 95, 139(1915).—Six samples were prepd. by different pharmacopeial formulas. EtNO₂ (1.84 to 2.5%) was present in all but 1; EtNO₂ (3.0 to 10%) was present in all specimens including one freshly made. EtCHO (0.01 to 0.8%) and paraldehyde (trace to 0.32%) were present in all but the fresh and 1 other sample. If sweet spirit of niter is not acid, or if it is neutralized, it becomes quite rapidly acid on keeping, small amts. of HNO₃, HNO₂ and AcOH being formed (0 to 0.27 N). The vaso-dilating action of the prepn. is due chiefly to EtNO₂; that of EtNO₂ and of EtCHO is relatively slight. Owing to the rapid loss of EtNO₂ upon adding H₂O it is best to prescribe the undil. prepn. and dil. it just before administering it.

S. WALDBOTT.

The new Norwegian Pharmacopeia; comparison with the Swiss Pharmacopeia, edition IV. AXEL JERMSTAD. *Schweiz. Apoth. Ztg.* 53, 533–7, 549–54(1915). S. W.

The British Pharmacopeia. C. BÜHRER. *Schweiz. Apoth. Ztg.* 53, 537–40(1915).—A discussion of H. W. Gadd, British and foreign pharmacopeias. Cf. *C. A.* 9, 510, 1915.

S. WALDBOTT.

Sterilization, purification and improvement of medicinal and laboratory glass. A. G. BARLADAN. Bern. Bot. Inst. *Schweiz. Apoth. Ztg.* 53, 605–8, 617–20(1915).—The method adopted is treatment of the inverted vessel for 15 min. with live steam generated in B.'s modification of Abegg's app. A sketch of the latter is given. Parallel expts. with 6 infected flasks show that sterilization was complete when heated in a steam autoclave, or when treated by the modified Abegg's process. In the flasks not treated

by steam, sterile bouillon became turbid within 24 hrs. The condensing steam also washes away impurities, *e. g.*, dead bacteria, or aq. solns., *e. g.*, of CuSO_4 . The *Spirogyra* test (C. A. 8, 989, 2778) proves this washing to be as efficient as treatment with brush and running water and allowing to stand for 24 hrs. with dil. HCl , then rinsing with distd. H_2O . A list of references is given. They are quoted also to show that steaming increases the resistance of the glass towards H_2O . S. WALDBOTT.

St. Germain tea. C. B. *Schweis. Apoth. Ztg.* 53, 645 (1915).—The prepn. of the Swiss Pharmacopeia is not homogeneous, because of the dry mixing of the ingredients. The German and Austrian pharmacopeias impregnate the fruits of fennel and anise with a soln. of $\text{KHC}_4\text{H}_4\text{O}_6$ (*i. e.*, solns. of $\text{K}_2\text{C}_4\text{H}_4\text{O}_6$ and $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$ applied successively). After drying, the material is mixed with senna leaves and elder flowers. C. B. proposes to triturate $\text{NaKC}_4\text{H}_4\text{O}_6$ with twice its wt. of H_2O and to saturate with it the cut elder flowers. After drying, the rest of the ingredients are incorporated to a homogeneous mass. The proportions are those given by the Swiss Pharmacopeia. S. WALDBOTT.

Volatile oil from leaves of Yabunikukei. Y. SHINOSAKI. *J. Chem. Ind. Japan* 18, 913-9 (1915).—Yabunikukei, *Cinnamomum pedunculatum* Nees, is widely distributed in the southern islands of Japan. The volatile oil of this plant, distd. from its fresh leaves, in Ogasawara Islands, has been investigated by S. The oil yield was about 1%. The oil is brown in color, somewhat like camphor oil in odor, and its constants are: d_{15} 1.0603, n_D^{20} 1.5284, $[\alpha]_D$ -1.75°, acid no. 0, ester no. 5.6, sapon no. after acetylation 25.25. The oil contains approx.: hydrocarbons and cineole 9%, eugenol 3%, safrole 60%, other oxygenated compds. 28%. M. I. W.

Volatile oil from leaves of Karasu-zansho. Y. SHINOSAKI. *J. Chem. Ind. Japan* 18, 1077-81 (1915).—Karasu-zansho, *Zanthoxylum ailanthoides* S. et. Z (Rutaceae) is indigenous to the southern parts of Japan. Oils distd. from the mature leaf, semi-mature leaf and young leaf, had the same characteristic odor and were a light orange-yellow. The remaining characters from the mature leaf oil, the semi-mature leaf oil and the young leaf oil were as follows: d_{15} 0.8437, 0.8385, 0.8390, n_D^{20} 1.4474, 1.4408, 1.4440, $[\alpha]_D^{20}$ -6.35°, -5.75°, -6.63°, ester no. 2.81, 4.21, 1.83. sapon. no. after acetylation 20.53, 14.96, 1.68. The principal constituents in these oils are methyl *n*-nonyl ketone, and a considerable quantity of terpenes and phenols (about 1.5% in the mature leaf oil). M. I. W.

Volatile oil from the leaves of Formosan Yamakosho. Y. SHINOSAKI. *J. Chem. Ind. Japan* 18, 1081-4 (1915).—S. has examd. an essential oil from leaves of Formosan Yamakosho, the botanical name of which is yet unknown. The oil, which was obtained with a yield of about 1.2%, had a light yellowish brown color, a camphoraceous odor, and the following characteristics: d_{15} 0.9049, n_D^{20} 1.4635, $[\alpha]_D$ 18.8°, sapon. no. after acetylation 48.66, insol. in 70% alc. It contains about 82% of hydrocarbons and oxides as shown by repeated distn. *in vacuo* over Na. In this oil, cineole was detected by prepn. of the iodole additive compound (m. 112°). Its content was about 49% by the resorcinol method, and therefore the oil contains about 33% of hydrocarbons. M. I. W.

Loss of weight of musk in a current of dry air. CHARLES B. BAZZONI. *J. Frank. Inst.* 186, 463-9 (1915).—A record of 2 expts. with an illustrated description of the app. used. The results seem to justify the following conclusions: Musk does lose wt. when exposed in a current of dried air. This loss is not due to the evapn. of water. After the loss of weight has ceased the musk is no longer odorous. The odor is not restored by exposure to moist air. The loss of weight is recognized to be due merely to the loss by evapn. of the volatile constituents of this particular specimen of musk.

The percent of volatile constituents must almost certainly be different in different samples, since musk as it occurs commercially is a complex variable mixt.

M. I. W.

The essential oil of *Eucalyptus smithii* from various forms of growth. HENRY G. SMITH. *J. Proc. Roy. Soc. N. S. Wales* 49, II, 158-69(1915).—A review, with illustrations, of information regarding the rapidity of growth and reproduction of the species under natural conditions of soil and climate; with a report of an investigation of the oil of *Eucalyptus smithii* distd. from material collected under different conditions of growth. The constituents present in the oil, besides pinene and cineole, are phenol, a small amount of volatile aldehydes, dextrorotatory eudesmol melting at 79°, a solid paraffin melting at 64°, a small quantity of esters, partly a low boiling one, probably butyl butyrate, and a small amount of sesquiterpene. Neither phellandrene, piperitone nor aromadendral have so far been detected in the oil of this species. Eight samples of oil showed the following variation in constants: d_{16}^0 0.9098 to 0.9210, $[\alpha]_D$ from +9.2 to +4.2, solubility in 70% alcohol from 1.1 to 2.1 vols.; saponification number from 1.3 to 5.6; cineol percent 61.5 to 85.2.

M. I. W.

The oil of the wild grape seed, *Vitis riparia*. GEO. D. BEAL AND C. K. BEEBE. *J. Ind. Eng. Chem.* 7, 1054(1915).—The source of the oil was the seeds from the wild grape obtained during the manuf. of grape butter. The seeds, after being freed from the dried pulp, were ground in a mill and extd. with low-boiling petr. ether; after evapn. of the ether, the oil obtained amounted to 19.38% of the weight of seed taken. The oil had a greenish amber tint, tasted like castor oil, and had a peculiar acrid odor. Physical and chemical exam. of the oil gave the following data: d_{18} 0.8425, n 1.4781, sapon. no. 187.8, I value 76.47, acetyl value 61.29, insol. 90.00%, fatty acids neutralization value 173.4. The quantity of oil available was too small for further studies on its compn. The authors expect to obtain a further supply and to continue the investigation.

M. I. W.

The stability of nitroglycerin tablets. WILBUR L. SCOVILLE. *J. Ind. Eng. Chem.* 7, 1054-5(1915).—There is a decided loss of nitroglycerin in the manuf. of tablets. This loss is now allowed for, the final adjustment being made by assay on a preliminary sample of tablets. The ratio of loss is not const. and it is necessary to test each lot during the process of manuf. The question of permanence, however, has not yet been decided. About 3.5 yrs. ago a series of sample tablets freshly made and tested, was set aside for observation. The results of the observation are presented in the form of a table from which it appears that all tablets containing less than $1/100$ of a grain each have deteriorated, and also, all those made from soln. of nitroglycerin, while tablets made from the paste, of $1/100$ grain or over, have maintained their strength.

M. I. W.

Constituents of oil of cassia. FRANCIS D. DODGE AND ALFRED E. SHERNDAL. *J. Ind. Eng. Chem.* 7, 1055-6(1915).—The essential oil of cassia is obtained in China by steam distn. of the bark and leaves of *Cinnamomum cassia*, but despite the fact that it is commercially one of the most important oils, its compn. does not seem to have been thoroughly investigated. The chief constituent is the well-known cinnamic aldehyde, the amt. of which, in pure oils, appears to vary from 75 to 90%. The examn. showed that the oil of cassia contained at least 0.5% of material sol. in dil. alkali, consisting of a mixt. of about 25% salicylaldehyde, 60% coumarin, 8-10% cinnamic acid, and small amts. of salicylic acid, benzoic acid and a volatile liquid acid, not identified. No phenol other than salicylaldehyde could be detected.

Vitamines from cod liver oil. C. FUNK. U. S., 1,162,907, Dec. 7. A concd. ext. of cod liver oil, containing vitamins, is made by treating the oil with ligroin, ether or dil. alc. This ext. is concd. by pptg. with EtOAc or acetone. The ppt. is taken up with dil. acid, pptd. with phosphotungstic acid, the ppt. is treated with acetone, and the residue with Pb acetate and the filtrate obtained is pptd. with H_2S to remove Pb and the purified soln. thus obtained is concd.

Obtaining vitamins from yeast, rice-bran, etc. C. FUNK. U. S., 1,162,908, Dec. 7. Phosphotungstic acid is added to yeast ext. and the ppt. formed is treated with acetone and then decomposed with Pb acetate and the excess of the latter removed with H_2S . The filtrate is evapd. *in vacuo* and white needles, m. 223° , and probably having the formula $C_{22}H_{24}O_8N_8$, are obtained.

Mesityl oxide. H. HIBBERT. U. S., 1,164,647, Dec. 21. Diacetone alc. is condensed by heating it with 0.01% of I to its b. p. A quant. yield of mesityl oxide is obtained. Pinacol distd. with 0.2% of I gives dimethyl butadiene. Cyclohexanol with 2% I, heated to $170-175^\circ$ for 60 hrs., gives tetrahydrobenzene.

3,5-Dinitro-4-methylaminobenzenearsonic acid. L. ACH, A. ROTHMANN and H. HATZIG. U. S., 1,162,496, Dec. 7. 3,5-Dinitro-4-chlorobenzenearsonic acid is reacted upon with methylamine in alc. on a H_2O bath and HCl added to ppt. the product. It is a yellow cryst. powder sol. in hot alc., glacial HOAc and NaOAc soln., insol. in acids, acetone or ether. 4-Amino-3,5-dinitrobenzenearsonic acid is made by reacting on 4-chloro-3-nitrobenzene-1-arsonic acid with NH_4OH , pptg. the mononitroamino deriv. formed with HCl and converting it into the dinitro compd. by further nitration with HNO_3 and H_2SO_4 . 4-Glycyl-3-nitrobenzene-1-arsonic acid is made by dissolving 4-chloro-3-nitrobenzene-1-arsonic acid in NaOH soln., adding aminoacetic acid, heating for 30 hrs. at 50° and pptg. with dil. H_2SO_4 .

Obtaining an ovarian product from the enclosing sacs. G. M. and W. I. HIEATZMAN. U. S., 1,163,538, Dec. 7. The ovaries are successively subjected to a bursting pressure in a closed vessel to cause extrusion of their contents which escape freely into the vessel. Sepn. from the membrane is effected by straining through a fine wire network while subjected to the action of a stiff brush.

18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

Potash from wood and plant ashes. HARLOW BRADLEY. *Met. Chem. Eng.* 13, 841-6(1915).—Since the European war stopped imports from Germany, considerable interest has been evinced in the possibility of producing potash from wood ashes, and the present paper deals with this phase of the subject. After a brief historical survey B. discusses the uses of potash, the manufacture of potash from wood ashes and the possible improvements in the method of manuf. The characteristic of potash produced from wood ashes, their practical utilization, some of the sources and the results of many analyses of plants and plant ashes, partly of European origin, are compiled in tabular form.

Chemical analysis of the mother liquor from R. Salina di Comacchio. MARIO ASQUINI. Univ. Padua. *Atti reale ist. Veneto, sci., lettere ed arti.* 74, 534-51(1915); see C. A. 9, 2294.

E. J. WITZEMANN.

Decomposition of ammonia and the chances of explosions. FRANK L. FAIRBANKS. Boston. *Power* 42, 715-7(1915).—Expts. in a large refrigerating plant, carrying a charge at times as great as 100,000 lbs. of NH_3 , failed to produce an explosion of NH_3 , or other gases by detonation. Mineral oil at high discharge temps. becomes a gas highly explosive when mixed with certain proportions of air. Segregated gases taken from the condenser or the absorber are explosive when mixed with the right amts. of air and ignited. The presence of Zn or Zn alloys in contact with the NH_3 at high temps. results in a decompn. of the NH_3 . The presence of foreign gases in a refrigerating system is indicated by a rise in both temp. and pressure, especially the condenser pressure, which may be readily observed on the gages. L. W. RIGGS.

Technical and academic chemistry. JAMES WALKER. *J. Soc. Chem. Ind.* 34, 1122-4(1915).—An address. E. J. C.

The World's Supply of Potash. London: The Imperial Institute. 47 pp. 1 s.

Concentrating nitric acid. F. RASCHIG. U. S., 1,163,174, Dec. 7. A mixt. of 50% HNO_3 1 and 92% H_2SO_4 2 parts is distd. at about 150° to obtain concd. HNO_3 and residual H_2SO_4 of about 60% strength. The latter is distd. at 150° under a high vacuum to reconcentrate to 92% so that the process may be carried on continuously by returning the H_2SO_4 to dehydrate fresh dil. HNO_3 .

Making ammonia from calcium cyanamide. W. S. LANDIS. U. S., 1,163,095, Dec. 7. A slurry is made of crude CaCN_2 , the slurry is heated by steam under 2-4 atm. pressure with $\text{Ca}(\text{OH})_2$ to initiate the reaction, and the latter is then allowed to continue with less application of heat, the heat of the reaction on evolution of NH_3 being sufficient to maintain the required temp. Cf. C. A. 9, 2699, 3333.

Copper oxide. S. G. MARTIN. U. S., 1,164,838, Dec. 21. A heated soln. of a Cu salt, e. g., CuSO_4 , containing KOH and KNO_3 is charged with air and then treated with steam under pressure to form CuO .

Aluminium chloride. B. T. BROOKS. U. S., 1,165,065, Dec. 21. A stream of Cl is passed through molten Al in a graphite vessel with sufficient rapidity to keep the metal agitated.

Soluble potassium and aluminium salts from silicate minerals. M. F. COOLBAUGH and E. H. QUINNEY. U. S., 1,165,154, Dec. 21. Powdered minerals such as feldspar or leucite are mixed with gypsum 2.8 parts for each part of SiO_2 in the mineral. The mixt. is heated to incipient fusion, quickly cooled, leached with dil. H_2SO_4 and K and Al sulfates are recovered from the soln. by crystn. Cf. C. A. 9, 696.

Basic magnesium carbonate. T. SILBERMANN. U. S., 1,163,475, Dec. 7. A dil. MgCl_2 soln. is mixed with a carbonated NH_3 soln. containing 8-10% NH_3 and 4-6% CO_2 so that the CO_2 is somewhat in excess of the amt. required to form basic Mg car-

bonate, the mixt. is heated until it assumes a curd-like consistency and the product is filtered and dried. It is a very voluminous granular material containing about 50% H_2O of crystn. Cf. C. A. 9, 360.

Apparatus for absorbing sulfur dioxide to form bisulfite solutions. P. A. PAULSON.

U. S., 1,165,281, Dec. 21. Milk of lime is supplied continuously at the pipe 22 and flows down from one chamber to another through the overflow pipes 24 while gases entering at 18 pass upward from one compartment to another through the pipes 20 and distributors 14.

Carbon dioxide and sodium sulfite. H. HOWARD. U. S., 1,164,649, Dec. 21. An aq. soln. of $NaHSO_3$ is reacted on with solid Na_2CO_3 , avoiding any excess of the latter over that required to form Na_2SO_3 . Less H_2O is used than would be required to maintain the product in soln. and a larger yield is thus obtained with an app. of equal size than when more H_2O is used.

Calcium cyanamide. E. GUI. U. S., 1,164,087, Dec. 14. N is allowed to react on CaC_2 while mixed with a much larger amt. of red-hot Ca cyanamide which prevents formation of a compact mass during the reaction.

Nitrogen compounds from distillers' washes. E. KOCHENDOERFER. U. S., 1,165,358, Dec. 21. Nitrogenous gases produced by carbonizing distillers' wash are conducted through hot tubes lined with quartz or ZrO_2 to produce CN compds. and NH_3 .

Reducing metals with hydrazine. N. SULZBERGER. U. S., 1,164,141, Dec. 14. Metals, such as Ni for use in hydrogenating oils catalytically, are reduced from their salts, e. g., Ni borate, by N_2H_4 in the presence of Pd or other catalytic metal (or Pt chloride) which serves to incite the reduction.

Heat-insulating material. F. J. JEWETT. U. S., 1,164,941, Dec. 21. A light, porous felt is made of asbestos paper stock and shredded sponge mixed with a small amt. of size and 25-40% of cattle's hair.

Electrical insulating material. J. FERLA. U. S., 1,165,164, Dec. 21. A mixt. of cement, hemp, HOAc, and glue is impregnated with linseed oil or other drying oil and baked.

Fire-proofed packing material. A. C. BORZNER. U. S., 1,165,062, Dec. 21. Waste cellulosic material such as corn stalks, or waste paper, is treated with an alk. soln. and reduced to pulp, fire-proofed, e. g., by treatment with borax, dried in sheet form and cut into shreds which may be used in the same way as excelsior.

Alginates from sea-weed. T. INGHAM. U. S., 1,162,926, Dec. 7. Alginates suitable for use in waterproofing or sizing fabrics are obtained by adding an excess of NH_4OH or other alkali to an alginate soln. obtained by extg. sea-weed with alkali and then an amt. of $CuSO_4$, $Al_2(SO_4)_3$ or $ZnSO_4$ or other metallic salt is added which in the absence of the NH_4OH or other alkali would be sufficient entirely to ppt. the alginic acid present. This forms a double alginate of alkali and other added metal. A small % of oil or wax may be added for waterproofing.

Iron oxide castings. L. SCHERBEL. U. S., 1,163,467, Dec. 7. Mixts. of Fe oxides containing over 3 times as much Fe_2O_3 as FeO and which may consist substan-

tially all of Fe_2O_3 are formed into castings by treating a melted bath of burnt pyrites with O under pressure while stirring, and casting in an oxidizing atm.

Alloy for dental fillings. T. J. DAVIS. U. S., 1,164,997, Dec. 21. An alloy of Au, Sn, Cu, Ag, Zn and Al is formed into granules, each of which is coated with Au. The granules are combined with Hg when prepd. for use.

Composition for impregnating or coating wood, leather, metals, etc. M. BUCHNER. U. S., 1,165,222, Dec. 21. Chlorinated mineral oil containing at least 30% Cl is mixed with a pigment such as Fe_2O_3 and a volatile solvent, *e. g.*, CCl_4 , alc. or turpentine. Chlorinated fatty oils or resin oils also may be used for acid-resisting coatings.

Preserving anatomical specimens, small animals, etc. P. DREGENER and W. BERNDT. U. S., 1,163,645, Dec. 14. See C. A. 9, 2298.

Sulfur dioxide; sulfites. F. J. STANES and G. S. ROGÉ. Brit., 18,605, Aug. 12, 1914. SO_2 is prepd. by heating S with NaHSO_4 or other acid sulfate in the absence of free O. A residue of mono-sulfite remains, and this may be converted into bisulfite by treatment with SO_2 .

Purifying salts. J. A. NEWBY and C. J. MONTGOMERY. Brit., 18,601, Aug. 12, 1914. Salts are purified by treating with a satd. soln. of the salt to be purified, and during this treatment, the salt is subjected to the action of surface tension by injecting air.

Salt pans. J. TODD. Brit., 18,701, Aug. 15, 1914.

Dust preventing compositions. H. F. T. LINDBALLE. Brit., 17,952, July 29, 1914. Roads are made dustless by treatment with hygroscopic salts, a substance containing sugar, and H_2O , applied consecutively or together and in such quantities that the salts substantially exceed the sugar material. A soln. of 100 lbs. of NaCl and 35 lbs. molasses in 600 lbs. H_2O is preferred.

Emulsifying. S. H. BLICHFELDT. Brit., 18,048, Oct. 18, 1913. Margarine and other emulsions are prepd. by a disk and a casing between which there is relative motion, the liquid being supplied to both sides of the disk, as by forming it with slots, so that the pressure thereon is balanced. Cf. C. A. 9, 1229.

Lubricants; distilling resin. PENSACOLA TAR AND TURPENTINE CO. Brit., 18,235, Aug. 1, 1914. A lubricant grease consists of mineral oils, set by milk of lime or other alkali, and the acid substance obtained when resin is distd. under reduced pressure or with superheated steam. The acid is said to be an isomer of abietic acid, and its proportion in the acid substance varies from 68 to 92%, according as the conditions vary from a 5 in. vacuum and temp. of 280–345° to a vacuum of 28 in. and a temp. of 270–305°. The acid substance resembles rosin in appearance, but may be soft or cryst.

Pure iron-free zirconium oxide. K. LEUCHS. Ger., 285,344, Mar. 7, 1914. To obtain pure ZrO_2 from the impure, especially Fe-containing solns., H_2SO_4 is added to the HCl Zr soln. in about the mol. proportion of $7\text{ZrO}_2:4\text{H}_2\text{SO}_4$, and the mixt. is boiled. Without the application of pressure a readily filterable, crystalline, Fe-free ppt. of a basic Zr sulfate is obtained, having the constitution $7\text{ZrO}_2, 3\text{SO}_3, 14\text{H}_2\text{O}$ (dried over H_2SO_4 of sp. gr. 1.64). The H_2SO_4 may be removed from the resulting ppt., even in the cold, by NH_3 or fixed alkalies, which is not the case with other basic sulfates of Zr. The pulverulent, finely divided product is obtained in this manner. It is especially suitable for use in enamelling. *E. g.*, 10 kg. Zr ore are finely ground and calcined with 5 kg. soda. The incandescent product is extd. with H_2O , HCl is added to the insol. residue, and the silicic acid is sepd. in the usual manner. Some undecomposed ore and silica remain, and these may be decomposed with a fresh amt. of soda. Fe_2Cl_6

present in the soln. of the $ZrCl_4$ is reduced, and then H_2SO_4 is added in the proportion stated above. The soln. is then heated to boiling, and the free acid is wholly or partly neutralized. The dense cryst. ppt. is washed out until no more H_2SO_4 is exhausted.

Stable colloidal metal solutions. ELEKTRO-OSMOSE AKT.-GES. (GRAF SCHWERIN Ges.) Ger., 285,025, Apr. 15, 1913. The stabilizing effect is produced by sol. silicic acid. This acid is mixed with a metal salt soln. and the latter is then reduced. Hydrazine hydrate is used as the reducing agent. *E. g.*, a dil. Au or Ag salt soln. is added to a sol. silicic acid of about 2.5% SiO_2 content, and this is then reduced in such manner that the metal seps. in the colloidal state. With hydrazine hydrate, a perfectly clear, brown Ag sol or deep blue Au sol is obtained.

Regulating the temperature of superheated steam. A. MUSMANN. Ger., 285,140, Apr. 29, 1914.

Separating water from steam. SCHMIDTSCHER HEISSDAMPF-GES. M. B. H. Ger., 285,141, Oct. 15, 1913.

Stirring liquids. M. WENDRINER. Ger., 284,577, Dec. 18, 1913.

Separating substances according to specific gravity. A. GRÜNDLER. Ger., 285,133, Oct. 30, 1912. Cf. C. A. 10, 102.

Heat-treating cork. GRÜNZWEIG & HARTMANN, G. M. B. H. Ger., 285,106 Nov. 3, 1907. Addition to 267,733 (C. A. 8, 998). The principal process is modified in that the heating and the compression is effected in 2 successive stages. The effectiveness of the heat treatment can be enhanced by the continued mechanical movement of the cork in free uniformly thick layers. The heating and the shaping are sep operations.

Porous pressed articles. H. RAMMLER. Ger., 285,148, Nov. 8, 1913. Instead of the heretofore employed alc., as a volatile addition to the material, solid volatile substances, such as $(NH_4)_2CO_3$, hartshorn salt, NH_4 carbamate, or NH_4 percarbonate are used.

Securing pulverulent, granular, or other material to paper or fabric. W. GOLOMBEK. Ger., 284,682, Nov. 16, 1913. As a binder is employed the intermediate product resulting from the production of caoutchouc regenerates by the soln. process. This product consists of caoutchouc regenerate, H_2O , and solvent residues. After drying the binder, the pulverulent material adheres firmly, and the adhesive properties are not influenced by heat or cold, or by H_2O and atm. changes.

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

A new glass; and an application of low reflectivity of glass for radiant heat. E. C. SULLIVAN AND W. C. TAYLOR. Corning Glass Works. *J. Ind. Eng. Chem.* 7, 1064- (1915).—A new borosilicate glass of high SiO_2 content and free from heavy metals and those of Mg-Ca-Zn group, shows very low thermal expansion and high resistance toward reagents. Its properties are: sp. gr., 2.25; mean linear coeff. expansion (19–350°), 0.0000032. Culinary ware made from this glass bakes more rapidly than metal wares due to much lower reflectivity to radiant heat. The glass withstands shock better than enamelled earthenware or crockery. Some data are given. C. H. KERR.

Copper-plate engraving for earthenware decoration. ANON. *Pott. Gaz.* 4 965-6(1915).—A brief description of the engraving of the plate and the reproduction of the design by printing on tissue paper and applying this to the ware.

R. K. HURSH.

The enamelling of cast-iron vessels. H. VOGEL. *Keram. Rundschau* 23, 109-10 (1915).—Hard, white cast iron gives a better surface for enamelling than soft gray iron, but is brittle and warps easily. Surfaces to be enamelled are chilled in casting, or hardened by S. Graphite in the iron affords a poor surface for enamel. Castings are cooled quickly to avoid sepn. of C as graphite. Castings should be of uniform thickness, about 2.5-3 mm. The raw iron should be dense, fine grained and not too soft. In general, the Si should be high, 2.3-2.7%, P about 1-1.8%, Mn about 0.6% and S as low as possible. Higher Mn makes iron too brittle. Thorough cleaning of castings by the sand blast without acid treatment is best, followed by dipping in NaHCO_3 soln. (1-1 $\frac{1}{4}$ kg. per 100 l. H_2O) and drying in air. The ground coat must be harder than the cover coat, about 70-75% SiO_2 being allowable, and must not be overburned. It should not be thoroughly fused in fritting and should be finely ground. The furnace should be at least at 950°. A single application of a cover coat containing about 10% SnO_2 is best.

R. K. HURSH.

SINGER, F.: Ueber den Einfluss von Tonerde auf die Schmelzbarkeit von Gläsern. Berlin: *Keramische Rundschau*. 75 Pf.

Molds for glassware. B. C. GILLIGAN. U. S., 1,165,003, Dec. 21. Press forms and dies for molding glassware are formed of coke, mixed with sufficient calcined lamp-black to fill the pores of the coke, and a binder of sugar or tar.

Uniting nickel alloy pipes to vitreous ware. R. G. MILLER. U. S., 1,164,840, Dec. 21. An alloy of Ni 65, Mn 22 and Fe 13% is used for making pipes, etc., which are united with vitreous ware before the latter is burned and, having about the same coeff. of expansion, remain firmly attached.

Refractory substances; silicon carbide. W. W. CRAWFORD. Brit., 18,439, Aug. 8, 1914. Refractory articles, such as bricks, tiles, crucibles, furnace linings, etc., are made by mixing SiO_2 , e. g., in the form of kieselguhr or washings from China-clay, with a substance such as refuse oil which will yield C on burning, heating to about 2000° till clinkered, and molding the ground clinker with Na silicate. W oxide may be added at any stage of the process. The clinker is stated to be a carbide of Si or similar thereto.

20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

Microstructure of concrete. N. C. JOHNSON. *Proc. Am. Soc. Testing Materials* 15, II, 171-229(1915); see C. A. 9, 1380.

A. A. KLEIN.

Action of sulfates on concrete. A. SARTORI. Breslau. *Chem. Ztg.* 39, 957(1915).—Three analyses are given of a concrete flower pot, showing the destructive action due to sulfates contained in the earth in the pot. Cf. C. A. 5, 1811; 8, 3107.

J. H. MOORE.

Effect of finer grinding and higher sulfur trioxide content on physical properties of portland cement. P. H. BATES. U. S. Bur. of Standards. *Proc. Am. Soc. Testing Materials* 15, II, 126-52(1915).—Physical tests were conducted with 10 cements (1) as received, (2) when ground so that about 12% more passed a 200-mesh sieve, (3) when the SO_3 content of the cement as received was increased to 2.5%, (4) when both the SO_3 was increased and the cement reground. Finer grinding produces a quicker set; additional SO_3 produces a quick initial but slower final set, although few of the changes are such as to place the treated cements beyond specification limits. Either

fine grinding, the SO_2 addition, or both, generally improves the strength of neat specimens, although the results are not consistent. The tensile strength of the mortars shows the advantage of all 3 treatments; the addition of SO_2 to the coarse cement causes a falling off in the rate of gain of compressive strength. With the "combined storage" method of aging, the tensile test on neat specimens does not show that the cements are improved by either of the treatments used, and the compressive results of these specimens are not conclusive. The sand tension tests are also not conclusive, whereas the sand compression tests do show the value of finer grinding with or without SO_2 addition. Tests on concrete show that finer grinding is very advantageous for early strength and that the addition of more SO_2 to such more finely ground cements more properly to control the set is not disadvantageous at this period. Expansion tests on neat H_2O -stored specimens show large increases in length for the specimens made from the cements containing more SO_2 , whereas in the mortars this is not so apparent.

A. A. KLEIN.

Weight-volume proportioning of concrete aggregates in testing. J. A. KRITS. *Proc. Am. Soc. Testing Materials* 15, II, 153-70(1915).—Arbitrary proportioning in mortar and concrete gives inconsistent results. It is necessary to know the sp. gr. and the % of voids of a material, in detg. the vol. of that material by weighing. A wt.-vol. method of progressive proportioning both for mortar and concrete is given.

A. A. KLEIN.

Strength and elastic properties of concrete-filled pipe columns. F. W. SWAIN AND A. F. HOLMES. *Proc. Am. Soc. Testing Materials* 15, II, 230-44(1915).—Tests made on concrete-filled pipe columns, filled by a jolting process, showed the columns to have a definite elastic limit and up to this load to be perfectly elastic, the steel pipe preventing permanent set from taking place in the enclosed concrete.

A. A. K.

Report of sub-committee C-1 on accelerated tests of cement. R. L. HUMPHREY *et al.* *Proc. Am. Soc. Testing Materials* 15, I, 147-8, Discussion 149(1915).—The autoclave test for soundness should not for the present be adopted because the investigations that have been made of this method do not show that it is in any way superior to the present test for soundness.

A. A. KLEIN.

Report of committee C-1 on standard specifications for cement. G. F. SWAIN *et al.* *Proc. Am. Soc. Testing Materials* 15, I, 144-6(1915).—Chapman's app. for consistency when operated in accordance with the method recommended by C., does not give sufficiently concordant results on 1:3 cement-sand mortars or on neat cement paste to warrant recommending its use as a reliable test for consistency. No further action is to be undertaken on the standard screen scale.

A. A. KLEIN.

Investigation on the test of portland cement for time of setting. TAKESHIKU HATTORI. *J. Chem. Ind. Japan* 18, 37-40(1915).—H. investigated to what degree detn. of setting time is affected by quantity, quality and temp. of gaging H_2O , temp. and hygrometric degree of atm., amt. of heat developed, aeration, etc. He recommends a test based on the amt. of heat developed, especially for quickly setting cements. In using the Vicat needle, he suggests applying it at 3 points to be vertices of a regular triangle on the surface of the pat, initial set being reached when all three needles are arrested 1 mm. above the level of the base and final set when all 3 needles are arrested 0.5 mm. from surface. Variations of humidity beyond 60% do not affect setting time. Setting tests should be made at the temp. of the atm. of the place when the cement is to be used. H. recommends, in making setting time tests, dividing the sample placing one portion in sealed bottles and spreading the other in a thin layer exposed to the air for a week or 10 days. If the aerated portion develops a quick set it should be

rejected. He also proposes making the test on mortars composed of very fine sand, as he finds that different cements show different setting times when mixed with sand.

C. N. WILBY.

Influence of prolonged infiltration of brine on construction materials. S. CAMILLA. Torino. *Ann. chim. applicata* 4, 145-50(1915).—Materials of building constructions that crumble on account of brine infiltration contain many substances lacking in the normal materials, as common salt and organic substances. Chlorides react with the CaO of mortars, forming deliquescent CaCl_2 , which keeps the masonry in a continual state of humidity, interfering with its setting and hardening. Nitrates similarly produce $\text{Ca}(\text{NO}_3)_2$.

S. LEVY.

Report of committee D-4 on standard tests for road materials. L. W. PAGE, *et al.* *Proc. Am. Soc. Testing Materials* 15, I, 325-31, Discussion 356(1915).—Rept. of proposed revised definitions. The Jackson sp. gr. app. is recommended for use in detn. of the sp. gr. of sand and fine aggregates. The cone sp. gr. method is recommended in detn. of voids in mineral aggregates. It is recommended that products of rock-crushing plants be covered in specifications by stating that the product shall conform to limitations given in terms of mechanical analyses made with lab. screens.

A. A. KLEIN.

Report of committee C-7 on standard specifications for lime. J. S. MACGREGOR, *et al.* *Proc. Am. Soc. Testing Materials* 15, I, 167-70, Discussion 171-2(1915).—**Specifications for quicklime:** There are 2 grades: (a) selected, shall be a well burned lime picked free from ashes, core clinker or other foreign material; (b) run-of-kiln, shall be well burned without selection. Quicklime is shipped in 2 forms: lump lime, shall be the size coming from the kiln; pulverized lime, shall be lump lime reduced in size to pass $\frac{1}{4}$ in. screen. Quicklimes are divided chemically into 4 types: high-Ca (over 90% CaO), Ca (not under 85% and not over 90% CaO), magnesian (10-25% MgO) and dolomitic (not under 25% MgO). Selected quicklime shall contain not under 90% CaO and not over 3% CO_2 . Run-of-kiln quicklime shall contain not under 85% CaO and MgO and not over 5% CO_2 . **Specifications for hydrated lime:** Hydrated limes are divided chem. into the 4 types specified for quicklime. The sample for testing shall be a fair av. of the shipment and shall be taken from the surface to the center of the packages, of which 3% shall be sampled. A 2 lb. sample should be immediately stored in an air-tight container. The non-volatile portion of hydrated lime shall contain not under 92% CaO and MgO. Hydrated lime shall contain not over 5% CO_2 and sufficient H_2O to fully hydrate the CaO present. The type and chem. properties shall be detd. by standard methods of chem. analysis. A 3-in. pat, $\frac{1}{2}$ in. thick at the center, tapering to a thin edge, shall be made on a clean glass plate, from a paste composed of equal parts by wt. of hydrated lime and vol.-constant portland cement, gaged with only sufficient H_2O to make the mixt. workable. This pat after hardening 24 hrs. in moist air shall, when exposed in a convenient manner to steam above boiling H_2O in a loosely closed vessel for 5 hrs., show no signs of popping, checking, cracking, warping or disintegrating.

A. A. KLEIN.

Report of special joint committee D-4 on definitions of road materials. P. HUBBARD, *et al.* *Proc. Am. Soc. Testing Materials* 15, I, 332-4(1915).—The rept. contains proposed standard definitions of non-bituminous road materials (crusher-run, dust, flour, matrix, spawl, stone chips), of bituminous road materials (solid bituminous materials, liquid bituminous materials, semi-solid bituminous materials, asphalt cement, native asphalt) and of terms applicable to materials relating to roads and pavements (blown petroleum, oil-gas tars, water-gas tars).

A. A. KLEIN.

Report of sub-committee D-4 on ductility tests. A. W. DOW, *et al.* *Proc. Am. Soc. Testing Materials* 15, I, Appendix IV, 349-51(1915).—Ductility of a bitumen is the distance in cm. that a briquet will stretch before breaking, when the chips containing the briquets are pulled apart under H_2O at $70^\circ F.$ at a uniform rate of speed of 5 cm. per min. The results on some bitumens by different operators were not concordant, a fact which is probably due to some physical change taking place in the sample.

A. A. KLEIN.

Report of sub-committee D-4 on the softening point. G. P. HEMSTREET, *et al.* *Proc. Am. Soc. Testing Materials* 15, I, Appendix III, 341-2(1915).—Softening points of different materials were detd. at 6 different laboratories using the ring-and-ball method and the cube method. While the former method showed itself to be more convenient and to give the more concordant results, its adoption as standard is not recommended until further refinements have been devised and other methods investigated.

A. A. KLEIN.

Report of sub-committee D-4 on penetration. L. M. LAW, *et al.* *Proc. Am. Soc. Testing Materials* 15, I, Appendix V, 352-5(1915).—The following penetration test is proposed: The normal penetration of bitumen shall be the distance in cm./100 that a standard needle will penetrate into it vertically and without appreciable friction in the apparatus at 25° under a load of 100 g. applied for 5 sec. The container shall be a flat-bottomed cylindrical dish 55 mm. in diam. and 35 mm. deep. The needles shall be R. J. Robert's Parabola "Sharps" No. 2. Carefully selected needles shall be compared with a standard needle and rejections made of those which vary more than 1 point from the penetration obtained with the standard needle on a sample having a penetration of approx. 60. The H_2O bath shall be maintained at a temp. not varying more than 0.1° from 25° . The vol. of H_2O shall be not less than 10 l. and the sample shall be immersed to a depth of not less than 10 cm. and shall be supported on a perforated shelf not less than 5 cm. from the bottom of the bath. The sample should be completely melted at the lowest possible temp. and stirred thoroughly. It shall then be poured into the sample container to a depth of not less than 30 mm. and allowed to cool in dust-free atm. not lower than $65^\circ F.$ for 1 hr. It shall then be placed in the H_2O bath along with the transfer dish for 1 hr. prior to making the test. At least 3 tests shall be made at points not less than 1 cm. from the side of the container and not less than 1 cm. apart. The penetration shall be an av. of the 3 tests whose values shall not differ more than 4 points between max. and min. When necessary to vary temp., time and wt. and in order to provide for a uniform method of reporting results when variations are made, the following combinations are suggested: at 0° , 200-g. wt., 1 min.; at 46° , 50-g. wt., 5 sec.

A. A. KLEIN.

The effect of leaking illuminating gas on bituminous pavements. GEORGE C. WARREN. *Proc. Am. Soc. Municipal Improvements* 21, 304-18(1915).—In expts. made by passing the gas for several weeks through vessels containing asphalt and asphalt sand mixts. the asphalt increased in wt., became liquefied and lost its binding power. The expts. show that leaking gas mains may cause very serious damage to bituminous pavements.

GEO. M. HUNT.

Experiments on the bleeding and swelling of southern yellow pine paving block. C. H. TRESDALE. U. S. Forest Products Lab. *Proc. Am. Soc. Municipal Improvements* 21, 267-86(1915); see C. A. 9, 240.

GEO. M. HUNT.

Fungus bed test of wood preservatives. C. M. CHAPMAN. *Proc. Am. Soc. Testing Materials* 15, II, 267-73(1915).—The specimens 12 in. long are placed upright in fungus bed with 3 in. above and 9 in. below ground. The bed is prepd. by mixing a quantity of pulverized sheep manure with screened loam. The preserving materi-

used include foreign and domestic coal-tar creosotes, water-gas creosotes, wood-tar creosotes, mineral oil, vegetable and animal oils and inorganic salts in soln. The methods of application are: cold dip, hot dip, and continued boiling followed by cooling in the preservative. It is an accelerated test, simple and easily carried out, giving comparative results of the behavior of the preservatives in exposures where the wood comes in contact with damp ground.

Mortar for laying brick, stone, etc. C. M. LONG. U. S., 1,162,790, Dec. 7. Burnt molders' sand which contains particles of Fe and slag is mixed with about 10-12% its wt. of $\text{Ca}(\text{OH})_2$.

Artificial stone. G. ATTERBURY. U. S., 1,163,060, Dec. 7. A building material into which nails or screws may be driven is formed of cement 100, asbestos fibers 23, cinders 160, and sand 133 parts. Cf. C. A. 9, 1837.

Glazing natural or artificial stone. P. FENAROLI. U. S., 1,164,710, Dec. 21. The stone is varnished with a soln. containing alkali silicate dissolved in H_2O and after drying in air the coating is successively treated with H_2O for several hrs., then with dil. fluosilicic acid and with an acid soln. of $\text{Al}_2(\text{SO}_4)_3$ or other sol. Al salt, to form a hard impervious coating.

Waterproofing wood. D. H. BIBB. U. S., 1,165,355, Dec. 21. Railroad ties or other wood is impregnated with waste sulfite liquor and then is heated to 300-350° for 20 min. to render the constituents of the waste sulfite liquor insol.

Fireproofing wood. G. B. SHIPLEY. U. S., 1,163,271, Dec. 7. Wood (*e. g.*, shingles) is treated under pressure with a bath of ZnCl_2 soln. in which cement and powdered sand or infusorial earth are maintained in suspension by agitation during the treatment.

Impregnating wood with preservatives. G. B. SHIPLEY. U. S., 1,163,270, Dec. 7. Wood is subjected to air pressure and, without releasing the air pressure, is treated with ZnCl_2 soln. or other preservative liquid under a greater pressure, then the liquid is withdrawn and the wood is subjected to a partial vacuum to ext. H_2O and excess preservative from it and finally is treated with a H_2O -proofing substance, *e. g.*, petroleum hydrocarbons, under pressure and the excess of H_2O -proofing agent is also withdrawn by a partial vacuum. Cf. C. A. 9, 2302.

Colored cements. J. C. PELTON. Brit., 18,520, Aug. 10, 1914. Portland or other cement, whiting, or Paris white is colored by first making a paste of H_2SO_4 and ordinary com. FeS , dilg. this paste with H_2O according to the tint required, adding this mixt. to the cement, etc., drying the product, reburning, and regrinding.

Asbestos-cement tiles. R. E. GOLIGHTLY. Brit., 18,005, July 30, 1914. The tiles are subjected to pressure and subsequently treated with steam in an autoclave. To prevent any of the press-expelled H_2O or H_2O of condensation in the autoclave from working back into the tiles, the edges of the tiles are dusted, while under pressure and after most of the excess H_2O has been expelled, with portland cement, slag

cement, hydraulic lime, etc. In carrying out the invention, the pile of tiles in the press is screened by a box and the cement dust is forced into the space between the tiles and box by an air or steam blast. To facilitate their subsequent separation, the tiles may be provided with 2 shoulders projecting through the cement layer, such shoulders engaging with a suitable frame to which a shock or blow is imparted.

Artificial stone from infusorial earth. J. A. ELLGASS. Ger., 285,350, July 22, 1913. Clean infusorial earth is mixed with xanthic acid prepd. from cellulose, then with viscose, and dried. The conversion of the cellulose into xanthic acid can be effected by means of NaOH or KOH. By employing KOH a greater degree of hardness is obtained, and this can be increased by increasing the content of alkali. The period of action of the alkali upon the cellulose required to bring this into soln. is 4 days at 20°. After soln., CS₂ is added to the alkali cellulose, and after 1-3 hrs. this is converted into the H₂O-sol. state. The 10% soln. obtained by the addition of H₂O is mixed with the infusorial earth, whereupon the alkali reacts with the SiO₂ to form water-glass which can be removed by rinsing. The binding agent seps. out as cellulose. After the mass has been shaped as desired it is subjected to a drying process which effects the coagulation of the dissolved cellulose. During coagulation the H₂O used is split off and evapd. The particles of infusorial earth remaining are united by the sepd. cellulose. Since this is insol. in H₂O, the resulting stone is therefore resistant to weather conditions. The insulating properties of the stone are said to be greatly increased by this treatment.

Continuous production of artificial stone slabs and conduits. L. HATSCHKE. Ger., 284,755, July 13, 1913.

21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

Industrial fuels and the European war. DOMENICO MENEGHINI. Padua. *Ann. chim. applicata* 4, 182-201(1915).—A review. Cf. C. A. 9, 365. S. LEVY.

Recent experiments in surface combustion. L. J. BRADFORD AND C. D. CORWIN. Cornell Univ. *Power* 42, 787-8, 855-8(1915).—Combustion is assisted when mixts. of gas and air are forced through an incandescent substance. The burning becomes flameless and much more rapid than under ordinary conditions. Apparently all combustion occurs on the surface of the granules composing the porous material, hence the name surface combustion. It is characterized by high temps. and great efficiency, complete combustion being obtainable with practically no excess of air. The application of surface combustion to the heating of steam boilers resulted in the attaining of very high efficiencies, which varied with the rate of combustion, increasing with the amt. of gas burned per hr. The max. temp. difference between the flue gases and the steam was only 41°, and the sensible heat lost in the waste gases varied from 3.5 to 4%. The main loss in the flue gases occurs as latent heat in the water vapor formed by the burning of H in the fuel. It is therefore best to use a gas low in H, such as producer gas from anthracite. L. W. RIGGS.

Cheapest fuel and most economical load. R. H. KARL. St. Louis. *Power* 42, 792-4(1915).—Ten very complete boiler tests made under working conditions showed that while the cost per ton of screenings was 44% less than that of high grade nut coal, its value as a steam producer was only 9% less. Increasing the load or flue gas temp. decreases the efficiency. A boiler should be worked at its rated capacity to secure the most economical results. L. W. RIGGS.

The heating and nitrogen problems after the war. EDUARD R. BESEMFELDER. *Chem. Ztg.* 39, 925-7(1915).—Instead of coking the coal, as advocated by Uhlmann (*C. A.* 9, 3124), B. recommends using the "mixed gas" process. J. H. MOORE.

Natural gas. D. HAGER. *Eng. Mining J.* 100, 959-61(1915).—A summary of our knowledge concerning the occurrence and origin of natural gas. E. T. W.

How much carbon dioxide to expect. VICTOR J. AZBE. St. Louis. *Power* 42, 712-4(1915).—Three tables are given showing the compn. of the fuel and percentages of CO₂, N, O, and SO₂ in the gaseous products of combustion for varying quantities of air when soft coal, anthracite, and fuel oil, resp., are used as fuels. It is shown that in order to make the CO₂ percentage high, there is danger of reducing the air supply so that incomplete combustion results. A chart shows that as the % excess of air used increases from 0 to 100, the % of O in the flue gases increases from 0 to 10.6; while an increase in excess of air from 100 to 200% is accompanied by an increase in the % of O in the flue gases from 10.6 to 13.7. L. W. RIGGS.

The continuous determination of the calorific value of fuel gases with Junker's calorimeter. F. B. LARKIN. *Chem. Eng.* 22, 208-9(1915).—L. gives the following equation for calculating the B. t. u. per cu. ft. of gas as detd. in a Junker calorimeter: $(\text{cc. of water} \times \text{range in } ^\circ\text{C.}) / (252 \times \text{cu. ft. of gas}) = \text{B. t. u. per cu. ft.}$ If 2520 cc. of water are used in the calorimeter the B. t. u. per cu. ft. is detd. simply by dividing the range in $^\circ\text{C.}$ by the cu. ft. of gas used and moving the point one point to the right. The detn. is made continuous by noting the temp. of the incoming and outgoing water and reading the gas meter every period (a period being the time necessary for 2520 cc. of water to pass through the calorimeter). The B. t. u. per cu. ft. detd. during each period will show any transient fluctuations in the calorific power of the gas, and the av. of many consecutive periods will give an accurate final value. F. L. GROVER.

Coppée regenerative ovens at Liege. *Gas World* 63, No. 1633, *Coking By-Product Section* 15-16(1915).—A description is given of the plant which consists of 112 ovens. According to the moisture in the coal the distn. period is from 24 to 27 hrs. The hydraulic mains are arranged for fractionation of gas of 550 B. t. u. or higher from the remainder 450-500 B. t. u. The by-product plant includes 3 rotary exhausters driven by an 80 h. p. motor, 3 vertical tubular H₂O condensers, 3 Pelouze tar extractors, 3 saturator and 3 vertical drying condensers. As gas is supplied for lighting purposes, there is no recovery of benzene. The complete records of trials of a 72 hr. continuous run are given. M. L. TROWBRIDGE.

Modern carbonizing systems in America. SOCIETY OF GAS ENGINEERING OF N. Y. CITY. *Trans. Intern. Gas Congress 1915* (advance copy), 5 pp.—A comparison of the carbonizing system of 19 different plants is made upon data based on actual operation. The unit of comparison is 2,000,000 cu. ft. per day. The data as well as plans and elevations of benches and retort houses are given. Analysis of the data shows the following facts: (1) The area required for a horizontal retort house of 2,000,000 cu. ft. daily capacity is from 9,433 to 16,416 sq. ft.; for inclined retort house 8,848 to 10,871 sq. ft.; for vertical retort house 4,800 to 6,945 sq. ft. (2) The cubical contents of the houses are 392,490 to 872,000 cu. ft., 491,164 to 578,212 cu. ft., and 300,000 to 400,000 cu. ft., resp. (3) The wt. of refractory material is 3,396,000 to 6,119,000 lbs. for horizontal, 5,356,400 to 6,690,400 lbs. for inclined, and 4,690,000 to 7,360,000 lbs. for vertical retort houses. (4) The total wt. of structural iron is 372,000 lbs. for horizontal, 394,500 to 498,600 lbs. for inclined, and 623,300 to 1,440,000 for vertical. (5) The labor required for 24 hrs. is 125 to 266 hrs. for horizontal, 147 to 200 hrs. for inclines and 57 to 106 for verticals. (6) The candle feet per lb. of coal vary from 62 to 95 for horizontals,

74 to 87 for inclines, and 83 to 97 for verticals. (7) The recovery of tar in gallons per ton is 10.80 to 13.65 for horizontal retorts, 11.06 to 13.29 for inclined, and 14.40 to 15.15 for vertical retorts. The free C in tar from horizontals and inclines averages over 24%, while less than 3% for verticals. (8) The max. NH_3 recovery per ton coal for a period of 6 months is 5.80 lbs. for horizontal and inclines, and 6.1 lbs. per vertical. (9) The furnace fuel per 100 lbs. coal carbonized averages 14.43 lbs. for horizontals, 12.32 lbs. for inclines, and 14.00 lbs. for verticals. From the tables it would appear that horizontals are low in first cost, easy to operate, and accessible; inclines require no mechanical stoking, permit of more inexperienced labor and are flexible in labor operation; while verticals require least ground space, operate on less labor, do away with smoke nuisance, and give higher yields of coke, tar and NH_3 . Vertical retorts are difficult to design so as to compensate for expansion of refractory material.

F. L. GROVER.

The composition of gas in relation to the performance of the Bunsen burner. R. S. McBRIDE. *Am. Gas Light. J.* 103, 353-5 (1915).—A critical study of the articles by Pierce (*C. A.* 9, 2305).

P. J. COLE.

Increasing the yield of hydrocarbons in gas and tar. ANON. *Gas World* 63, No. 1633, *Coking and By-Product Sec.* 14 (1915).—There has been promulgated lately a large number of processes for increasing the yield of light oils, etc., from coal, but the majority of these have been confined either to purely low temp. distn. or to the cracking of heavy oil. In the Rollason process, exploited by the Synthetic Gas Processes Co., limestone is added to the crushed coal before distn. and is said to increase the amt. of hydrocarbons, especially toluene. Certain essential facts are not mentioned, as to the class of coal, the amt. of limestone used, the amt. of ash in the coke or the action of lime on the brickwork of the ovens. It is claimed, however, that by the process the quality of the coke is improved, that it is especially suitable for a poor quality coking coal. Comparative results are given which show that by the addition of limestone to the coal the distillate can be increased from 4.28 gals. to 6.55 gals.; toluene in the distillate from 2.96 lbs. to 3.8 lbs.; toluene recovered from tar from 0.14 to 0.41 lbs.; B. t. u. per cu. ft. of gas after washing 537 to 555; cu. ft. of gas after washing from 11,510 to 11,928; also that the S in the gas was decreased, the yield of $(\text{NH}_4)_2\text{SO}_4$ was increased and the tar improved in quality.

M. L. TROWBRIDGE.

Loss of ammonia in storage of ammoniacal liquor. W. S. CURPHEY. *Gas World* 63, 539 (1915); *J. Gas Lighting* 132, 424 (1915); *Chem. Trade J.* 57, 496 (1915).—Attention is called to the serious loss of NH_3 which is likely to occur when liquor is stored under conditions which admit of air circulation above the surface. The suggestion is made that a layer of oil covering the surface of the liquor when in the storage tank might be found serviceable in preventing this loss and it is further pointed out that oxidation changes which result in the formation of fixed salts of NH_3 would, at the same time, be retarded with the ultimate saving of CaO and alkali in the fixed NH_3 still. Tests show that the loss of free NH_3 where oil has been used was from 0.3% to 0.5% and without the use of oil the loss was from 20% to over 40% in 80 days. 0.1 in. of mineral oil should afford complete protection.

M. L. TROWBRIDGE.

The development of refined tars for use in road construction and maintenance. PHILIP P. SHARPLES. *Met. Chem. Eng.* 13, 918-20 (1915).—The physical properties and compn. of six classes of raw tars are compared, and also the influence of the nature of the raw tar upon the physical properties and compn. of the refined soft pitch. The sp. gr. and the amts. of free C and fixed C in the soft pitches advance in the same order as in the original raw tar. Refined tars are used for construction of macadam roads, road-blanket treatment, cold-surface treatment, and as a filler in block pavement.

The proper specifications covering materials for these uses are discussed with respect to sp. gr., % distillate below 315°, m. p., free C, and viscosity. F. L. GROVER.

By-product coke. ANON. *Iron Age* 96, 935-6(1915).—A discussion of the recent report by the Geological Survey on the coke industry for 1914. F. L. GROVER.

Development of the by-product and coking industry of Great Britain. GEO. CHRISP. *J. Gas Lighting* 132, 539-41(1915). E. J. C.

Gas producer. G. M. S. TAIT. U. S., 1,165,347, Dec. 21.

Carbureted producer gas. T. F. FITZSIMMONS. U. S., 1,164,081, Dec. 14. Air is passed through a bed of fuel to form producer gas and the gas is burned in a chamber where the gas is to be carbureted until the chamber is sufficiently heated. Then oil and gas are supplied to the chamber to produce a fixed carbureted gas and the operation is repeated intermittently.

Method of blasting fuel charges in making producer gas. P. G. SCHMIDT. U. S., 1,164,408, Dec. 14.

Gas scrubber. G. M. S. TAIT. U. S., 1,165,348, Dec. 21.

Making ammonium sulfate. A. F. HILLEKE. U. S., 1,163,752, Dec. 14. Ammoniacal gas is washed with H₂O condensed from the gas to remove tar and fixed ammoniacal compds. and the excess of condensed moisture is reheated and continuously circulated in contact with the gas to vaporize and return to the gas the H₂O of condensation and free NH₃. The gas is then passed through a bath of acid to form (NH₄)₂SO₄ and the H₂O condensed in the bath is vaporized and returned to the gas to prevent diln. of the sulfate bath.

Determining the amount of benzene in gas. C. L. O. GRAUL. U. S., 1,163,654, Dec. 14. A continuous test of the gas as produced may be made by removing C₁₀H₈ from a test portion by treatment with picric acid, dividing the test portion into 2 parts and removing C₆H₆ from one of them, *e. g.*, by absorption in oil, and then burning the 2 parts at separate burners and comparing the illuminating value of the flames.

Saturator for absorbing ammonia in acid. A. F. HILLER. U. S., 1,163,753,

Dec. 14. Ammoniacal gas is supplied through the inlets and acid is delivered into the app. through the pipes *d, d'*, and the gas is brought into contact with the acid by passing under the serrated edge of the baffle *C*, which extends below the surface of the acid. Fresh acid from the supply through *D, D'* flows down over the surface of the baffle *C* and cuts away any salt that has formed upon the baffle.

Carbon monoxide from carbon dioxide.

C. B. HILLHOUSE. U. S., 1,163,922, Dec.

14. Powdered C is forced with a swirling motion by gas under pressure into a stream of CO₂ and the mixt. is heated to a reducing temp. A flux may be added to the C.

Gas from peat. N. TESTRUP, T. RIGBY

and O. SÖDERLUND. U. S., 1,164,429, Dec. 14. A fluid pulp of peat is heated under pressure to above its normal b. p. (the pressure being sufficient to prevent boiling, immediately filter-pressed and dried in a current of hot gases, briquetted and converted into fuel gas, from which NH₃ may be recovered.

Treating coal. F. BERGIUS. Brit., 18,232, Aug. 1, 1914. Coal and similar substances produced by natural or artificial carbonizing are treated for the production of hydrocarbon and other bodies by reaction with H or substances giving off H. By heating coal with H, e. g., at 400°, and under a pressure of 200 atms., liquid products suitable for use as burning or motor oil are obtained. The operation may be effected in the presence of benzine or other solvent for the products. The N of the coal is obtained as NH₃, or the NH₃ may previously be distd. off at 300–500°. The hydrogenation may be effected simultaneously with the carbonization of wood, peat, and other vegetable substances.

Preparing peat. WETCARBONIZING, LTD. Brit., 18,030, May 10, 1913. In processes for heating peat, with or without the use of acids or other auxiliary means, and subsequently removing H₂O, the latter operation is effected in filter presses at temps. of 60° and over, and part of the hot effluent is mixed with raw peat, from which some of the natural H₂O may be first removed by draining, air-drying, or pressing. The percentages of H₂O before and after addition of the effluent may be 85 to 94–95%, resp. A suitable app. is specified. Cf. C. A. 9, 2812.

Destructive distillation. H. G. HILLS. Brit., 18,576, Aug. 12, 1914. Carbonaceous material such as coal, the dust of bituminous fuel, etc., without agglutinants and in a movable container, is introduced into a vacuum chamber and thence transferred into one or more distg. chambers, where it is distd. at a temp. below or but slightly exceeding that at which tar is formed, and is then passed in a plastic condition into a cooling chamber, where it may be compressed.

Furnaces for destructive distillation. W. W. CRAWFORD. Brit., 18,437, Aug. 8, 1914. A rotary retort furnace for the continuous destructive distn. of carbonaceous substances comprizes a series of vertical retort chambers and intermediate heating chambers arranged radially around a central vertical axis about which the whole series of retorts and heating chambers rotate, the charging and discharging of the retorts being effected automatically during rotation.

Ammonia; fertilizers. T. RIGBY and WETCARBONIZING, LTD. Brit., 18,558, Aug. 11, 1914. NH_3 is absorbed from gases such as those obtained in peat gasification, as by the processes described in 17,610, 1911, and 25,146, 1912, by means of peat which has been subjected while wet to a heat treatment which renders its H_2O readily expressible as described, *e. g.*, in 10,834, 1903, 17,610, 1911 (C. A. 7, 411), 17,427, 1912 (C. A. 8, 416), 5,873, 1913 (C. A. 8, 2939), 9,392, 1913 (C. A. 8, 3359), and 11,133, 1913 (C. A. 8, 3499). The peat containing NH_3 is suitable for use as a fertilizer.

Ammonium sulfate. T. RIGBY and WETCARBONIZING, LTD. Brit., 18,559, Aug. 11, 1914. In the treatment of producer and like gas for the recovery of NH_3 as sulfate, discoloration of the sulfate is prevented by treating the sulfate liquor with oil such as is contained in the lighter fractions from distn. of the tar produced in making the gas.

Coking. F. L. SLOCUM. Brit., 18,215, Aug. 1, 1914. In a continuous coking oven or retort, the upper part of a retort, or an extension of the retort below the hopper, is contracted to form a shoulder to prevent the semi-plastic mass from rising and choking the feeding channel when the pressure ram is raised.

Firing furnaces. B. STOUGHTON. Brit., 18,499, Aug. 10, 1914. See C. A. 9, 51.

Apparatus for thoroughly mixing gases in gas holders. M. NIEMANN. Ger., 284,538, May 22, 1913.

Cleaning, cooling, and mixing gases. H. E. THEISEN. Ger., 284,858, Feb. 8, 1914. Addition to 265,639 (C. A. 8, 818).

Producing generator gas in revoluble tube furnaces. ALPINE MASCHINENFABRIK-GES. M. B. H. v. HOLZHAUSERSCHE MASCHINENFABRIK G. M. B. H. Ger., 285,311, Jan. 11, 1913. Any organic matter, regardless of its physical properties, may be treated by this process automatically. The necessary amt. of gas containing CO_2 , for effecting gasification of the material, is introduced at such temp., and with such a composition, that the slags do not melt. This is effected by carrying out in an auxiliary chamber of the revoluble tube furnace, to which the hot gases are conducted, the oxidation process carried out heretofore in the furnace itself and which was accompanied by fusion of the slag. The prevention of fusion of slag permits the process to be made continuous.

Removing tar from hot distillation gases. BERLIN-ANHALTISCHE MASCHINENBAU-ART.-GES. ABTHEILUNG CÖLN-BAYENTHAL. Ger., 284,971, Sept. 29, 1912.

Operation of coke ovens. BERGWERKSGES. TRIER M. B. H. Ger., 284,863, Aug. 26, 1913. The low temp. of the distn. gas, after the sepn. of the tar, serves to cool the heated cooling H_2O .

22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

F. M. ROGERS.

Committee report on penetration (LAW) 20. Committee report on the softening point of materials (HEMSTREET) 20. Committee report on ductility tests (Dow) 20. Petroleum in Colombia (MANNING) 8.

KEAN, F. J.: *Petrol Engine*. London: E. & F. N. Spon. 140 pp.

Distilling petroleum. L. STEWART. U. S., 1,163,570, Dec. 7. Crude asphaltic petroleum is progressively heated in different chambers as it is passed from one to the

other and vapors are taken off by relief valves between the heating chambers and the last portion of vapors is led back to heat the first chamber.

Refining petroleum. F. W. MANN and M. L. CHAPPELL. U. S., 1,163,025, Dec. 7. Petroleum is treated with alc. and liquefied SO_2 at a temp. below 0° to dissolve aromatic hydrocarbons.

Refining petroleum oils. J. C. BLACK. U. S., 1,164,162, Dec. 14. Petroleum is treated with SO_2 under pressure and allowed to sep. into 2 layers. The bottom layer is withdrawn and its gas pressure reduced which causes it to sep. into layers. The second bottom layer thus formed is removed and relieved of its gas pressure. The first and second top layers also are freed from absorbed SO_2 and then are mixed together and further freed from residual SO_2 , and the top layer mixt. and 2nd bottom layer are separately collected, the SO_2 being reused in treating fresh crude oil. Cf. C. A. 9, 2814.

Refining asphalt. C. N. FORREST. U. S., 1,163,593, Dec. 7. Loss of S from the asphalt is prevented during refining by the addition of linseed, soy bean, tung, fish or petroleum oils or other S-absorbing oil to obtain the desired balance of cohesion and adhesion of the asphalt cement produced, for use in paving mixts.

Petroleum oils. W. O. SNELLING. Brit., 18,419, Aug. 7, 1914. Products resembling a high-grade petroleum, yielding substantial proportions of gasoline and lamp-oil fractions, are obtained from low-grade crude oils and petroleum products such as gas oil, by heating them to a temp. such that the vapors evolved will produce an added pressure of at least 400 lbs. per sq. in., the quantity of liquid in the container being such that it occupies not less than one-tenth and not more than seven-tenths of the total capacity of the container. The operation may be effected in the presence of a catalyst such as colloidal graphite, colloidal C (formed by producing an arc between C points immersed in the oil), or Ni or other metal in the colloidal form, or in the presence of gases and vapors such as H, natural gas, ethylene, oil gas, water-gas, or steam. Temps. in excess of 380° and below 600° , preferably between 400 and 500° , are employed. Pressures between 600 and 800 lbs. per sq. in. are preferred, though a pressure of 2400 lbs. per sq. in. may be employed. According to one method of treatment, the oil is heated until the pressure reaches 800 lbs. per sq. in., and is then allowed to cool. The permanent gases are allowed to escape, and may be used for heating or for making propane or butane. The oil is fractionated up to 150° , and the residue is subjected to a further treatment. Certain oils, after being treated and cooled rapidly, polymerize to an "asphalt" at ordinary temps. in 24-48 hrs.; such oils, whether the gasoline and kerosene fractions have been removed or not, may be used for impregnating wood. In another form of treatment, after the oil has been heated up to the requisite temp., a valve communicating with a condenser is opened, and the gases and vapors are allowed to escape until the pressure falls to 400-500 lbs. per sq. in.; the valve is then closed, a fresh quantity of oil is added, and the treatment is repeated. An app. for continuous operation is specified.

Obtaining light oils. A. ROLLASON. Brit., 18,490, Aug. 10, 1914. In the manuf. of light oils having d. between 0.90 and 0.98 from carbonaceous substances such as crude oils, coal, cannel or coal shale, approx. 4 to 6% of limestone, proportionate to the d. of the oil required, is added to the charge, which is distd. slowly at a temp. below 400° . The retorts employed may be of cast Fe and, when heated from two sides, may be from 3 to 6 in. in width. They are set in brickwork, etc., to store heat, which is absorbed by the charge at the period of distn. at which H_2O and hydrocarbon vapors are formed. The temp. may be maintained between 175 and 400° according to the d.

of the oil required. The water vapor acts as a carrier for the hydrocarbons and prevents their decompn. Cf. *C. A.* 9, 711.

Motor spirit. T. FRANKS. Brit., 18,226, Aug. 1, 1914. A fuel for internal-combustion engines consists of aliphatic carbinols produced from raw peat, *e. g.*, as described in 28,072, 1913, mixed with an equal quantity or less of benzene, crude or refined. The benzene and carbinols are preferably mixed as gases during distn.

Cracking high-boiling hydrocarbons. GES. FÜR VERWERTUNG VON KOHLENSTOFF-VERBINDUNGEN M. B. H. Ger., 284,118, July 20, 1912. The hydrocarbon vapors rising from the distn. vessel are conducted first through a vessel, the temp. of which is regulable and independent of the heating of the distn. vessel, and then to the condenser. A suitable app. is detailed.

Ceresin (ozokerite), paraffin and other hydrocarbons. J. M. AZ. Ger., 284,045, Apr. 25, 1912. These products are obtained from mineral oil residues and tar. Cf. Brit., 10,256, 1912 (*C. A.* 7, 3539).

23. CELLULOSE AND PAPER.

A. D. LITTLE.

Making paper pulp from cotton stalks. W. H. CROLL. U. S., 1,165,323, Dec. 21. The stalks are soaked in H_2O to cause them to expand, cooked in lime H_2O containing a small amt. of NaOH and more lime is added to replace that consumed by combination with the resinous and fatty constituents of the stalk until all the latter have been combined with the lime.

Paper-pulp from flax straw. J. H. MELCHERS. U. S., 1,162,797, Dec. 7. Flax straw fiber after sepn. from the woody portion is cooked under pressure in a soln. of K_2CO_3 , pressed and washed.

Waterproofing paper. G. R. WYMAN. U. S., 1,165,367, Dec. 21. Before applying asphalt or similar waterproofing material to paper it is heated nearly to its flash point, while out of contact with air, to render the material very fluent and give more rapid impregnation.

Resin glue substitute for paper sizing. H. BURCKHARDT. Aust., 5,124, June 14, 1912. Vegetable size, together with other paper-sizing agents, is used. The resin soap obtained by boiling resin with alkali is mixed at 90° with vegetable size obtained by cold stirring of potato flour with NaOH soln., and finally animal glue is incorporated with this mixt.

Paper. C. G. SCHWALBE. Brit., 18,199, Aug. 1, 1914. In mfg. cellulose or half-stuff from wood or similar crude vegetable material by means of bisulfite soln., the material, suitably cut up, is impregnated with one of the usual $Ca(HSO_3)_2$ solns., either hot or cold, and with or without the aid of a vacuum; the impregnating liquid is then drawn off, SO_2 gas is added in sufficient quantity to double the amt. present in the wood, and the material is then steamed. The treatment is continued until it is possible to sep. the bundles of ligneous fibers while partly destroying the binding substance, *e. g.*, in an edge-runner, or until the material is opened up into cellulose or half-stuff. The introduction of SO_2 and steam may be effected together.

Acylcelluloses and their permanent solutions. KNOLL & CO., CHEM. FABRIK. Ger., 284, 726, Feb. 2, 1912. Addition to 203,178 (*C. A.* 3, 493). These solns. are obtained from cellulose and org. acid anhydrides in the presence of acid sulfates and an indifferent solvent or diluent. The bisulfates or their mixts. with neutral salts, with exclusion of free H_2SO_4 in the reaction product, are employed in amts. less than 0.5

part of the cellulose. The reaction must be stopped before the production of acetone-sol. products. By employing bisulfates of the alkali series or their mixts. with alkali sulfates, temps. above 80° must be employed.

Thick parchment tubes. G. H. SACHSENRODER. Ger., 284,470, Aug. 3, 1913. The parchment paper is rendered pliable by impregnation with a hygroscopic agent, and then led through a parchmentizing fluid in the desired number of strips; these are then pressed together and led through a water-bath.

Wood pulp for paper manufacture. F. FRIEDSAM. Ger., 284,420, Oct. 5, 1913. A mineral filling (kaolin, talc, blanc fixe, or the like) is added to the pulp during its working on the pulping stone. The filling material is forced into the fibers of the wood by the pulping pressure, so that the splitting and sepn. of the fiber structure is hastened and a fine slimy product is obtained. An economy in power is realized inasmuch as the added earths serve both as a lubricant for the pulping stone and as a disintegrating agent for the wood.

Wood pulp for paper manufacture. F. FRIEDSAM. Ger., 285,123, Jan. 1, 1914. Addition to 284,420 (*supra*). The pulp resulting from the treatment specified in the principal patent is placed directly in the pulping cylinder and from there it is conducted to the paper machine. In order that other fibers, such as cellulose, may be incorporated with this wood stock without sepn. during dyeing, these are first worked up in the pulper and impregnated with the filling.

24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE.

The explosive pressure of unenclosed explosives. A. HUBERTH. *Z. ges. Schiess-Sprengstoffw.* 10, 281 (1915).—An app. is described for detg. the explosive pressure of free lying bodies. An iron plate is supported between two vertical rods partly by rollers placed against them and partly by a guiding rod extending from the center of the plate and passing through a plate which connects the two iron rods at the top. On the top of the guiding rod at right angles to it is fastened a flexible pencil with its point against a rotating drum by which means the course of the plate is marked. In performing the expt. the cartridge is fastened to the bottom of the movable plate and exploded. The plate is driven up to a point s by the expansion of the gases and from there on it goes upward by the impetus it has received. After the inertia of the plate has been overcome the plate rises with increasing velocity to the point s and then the velocity decreases to zero. By drawing tangents to the curves for increasing and for decreasing velocity, the point of greatest velocity and the time at which the effect of the expanding gases ceases are found. The time interval between any two points on the curve may be calcd. from the distance between them and the rate of rotation of the drum. If Pk is the pressure working through the distance S and forcing the plate of weight G to the height H , then $Pk = GH/S$ and the mean velocity is h/t . O. L. THOMAS.

Tetra- and pentanitrodimethylaniline. *Z. ges. Schiess-Sprengstoffw.* 10, 295 (1915).— $(NO_2)_4C_6H_2NMe_2$ or tetralita No. 1 is formed by dissolving 1 pt. by wt. of $PhNMe_2$ in 10 pts. by wt. of concd. H_2SO_4 and pouring the cooled mixt. slowly into 5 pts. by wt. of concd. HNO_3 at a temp. of $30-40^{\circ}$. After the completion of the nitration, the product is centrifuged to remove the excess acids, then washed, and completely dried. It m. $125-8^{\circ}$. $(NO_2)_5C_6H_2NMe_2$ (Pentalita No. 2 or Pentalita) is formed by

dissolving PhNMe_2 in H_2SO_4 and pouring into HNO_3 previously heated to 120° . It is freed from acid as described above.

O. L. THOMAS.

New Swedish explosive for shells. IRA N. NORRIS. *Commerce Reports* No. 270, 675(1915).—It is styled Kausolit and its characteristic ingredient is NH_4ClO_4 .

CHARLES E. MUNROE.

The explosibility of acetylene. G. A. BURRELL AND G. G. OBERFELL. Bureau of Mines, *Tech. Paper* 112(1915).—The smallest proportion of acetylene capable of propagating flame in a mixt. of acetylene and air is 2.53%. The largest proportion of acetylene capable of propagating flame in a mixt. with air is 73%. Acetylene, not mixed with air, is explosive under a pressure of 3 to 5 atms. when an elec. spark is passed through the mixt. or when a Pt spiral is heated in it. The danger connected with the handling of CaC_2 in a mine is remote if reasonable care is observed in handling.

CHARLES E. MUNROE.

Military explosives. T. S. WILKINSON. *Proc. U. S. Nav. Inst.* 41, 1925-32 (1915).—This is a popular review but it embodies a calcn. of disruptive pressure of picric acid arriving at a result of 100+ short tons per sq. in. at the moment of detonation.

CHARLES E. MUNROE.

The Ardmore, Oklahoma, explosion. B. W. DUNN. Bureau of Explosives, *Special Bulletin* No. 2 (1915).—The explosion on Sept. 27, 1915, which killed 39 and injured 30-150 persons, and which destroyed \$500,000 to \$1,000,000 of property was primarily due to the shipping of casing head gasoline, having a large coeff. of expansion, in a tank car which was so overfilled with the material at a low temp. as to cause its vaporization and escape from the tank car when it was later exposed to higher natural temps. The condition was aggravated when the dome cap was unscrewed before the car and contents had been cooled down according to recognized practice because the vapors, mixed with air, then reached out to a source of ignition, of which several were about. A characteristic feature of this explosion was that the vapors appeared to mix with the air at a temp. sufficiently high to bring about an explosion in the air. This has previously been observed in other instances of conflagrations where tank cars containing gasoline were involved.

CHARLES E. MUNROE.

Decomposition of ammonia and the chances of explosions (FAIRBANKS) 18.

MARTIN, G. AND BARBOUR, W.: **Industrial Nitrogen Compounds and Explosives.** London: C. Lockwood & Son. 125 pp. 7 s, 6 d.

Blasting gelatin. A. T. COCKING. U. S., 1,164,170, Dec. 14. Wet nitrocellulose is incorporated with nitroglycerin and the mixt. after being warmed and shredded is subjected to reduced pressure to remove the moisture and then is consolidated into the desired shape.

Forming approximately spherical grains of explosive. E. DU PONT. U. S., 1,162,757, Dec. 7. A pasty mass of black gunpowder or similar explosive mixt. is divided into particles which are partly dried and then rolled upon a heated surface.

Explosives. E. VON HERZ. Brit., 17,961, July 29, 1914. The use of normal Pb salt of trinitroresorcinol in percussion caps and similar percussion and friction primers. This salt is obtained as a ppt. by mixing multiples of equiv. wts. of a Pb salt of a strong acid such as $\text{Pb}(\text{NO}_3)_2$, and an alkali or alk.-earth salt of trinitrore-

sorcinol in hot aq. soln. in the presence of a weak organic acid, such as HOAc, in very dil. soln.

Hexanitrodiphenyl. SPRENGSTOFF AKT.-GES. Brit., 18,333, Aug. 7, 1914. Use of hexanitrodiphenyl alone or mixed with other ingredients as an explosive for shells, mines, torpedoes, primers, and detonators. The hexanitrodiphenyl is prepd. by treating chlorotrinitrobenzene dissolved in 3 to 4 times its quantity of toluene or nitrobenzene with about a quarter of its wt. of Cu. After the reaction is over, the solvent is expelled by means of steam; the Cu_2Cl_2 is removed by washing with dil. HCl; and the hexanitrodiphenyl is recrystd. from HNO_3 .

Storage of explosives. SPEZIALGES. FÜR BETON- UND MONIERBAU SCHLÜTER. Ger., 285,105, Feb. 21, 1913.

25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

The dyestuff situation in England. L. A. OLNEY. *Trans. Nat. Assoc. Cotton Manufacturers* 98, 425-40(1915).—Historic and economic review of dyestuff industry of Gt. Britain with special references to present irregular conditions and means taken to relieve them.

R. B. STODDARD.

Report of committee D-13 on standard tests and specifications for textile materials. W. D. HARTSHORNE, *et al.* *Proc. Am. Soc. Testing Materials* 15, I, 440-2(1915).—This committee, which has so far limited its activities to tests and specifications of bags, bagging materials and tire fabrics, reports that further investigation is necessary on the subject of bags and bagging materials before standards can be formulated. Extensive tests upon tire fabrics made it possible to draft "tentative tests for automobile tire fabrics" to be used during the coming year in order to obtain information upon which to establish standard specifications (cf. tentative standards, 1915 year-book of the Society). The discussion closes with a description of "a 10-inch steel count scale."

L. W. RIGGS.

Waterproofing of military fabrics. G. A. LE RÔY. *Compt. rend.* 161, 602-4 (1915); cf. *C. A.* 9, 382.—A method in general use consists in treating the fabric with a bath of an Al salt, followed by a bath in a soap soln., whereby palmitates, stearates, etc., are pptd. on the fiber. The astringent action of the Al bath tends to prevent penetration by the soap soln., and to overcome this objection Le R. uses one bath containing a mixt. of aq. solns. of NaAlO_2 and a Na soap, to which, if desired, various adjuvants such as casein, gelatin, or resinous substances may be added. The goods are treated in this bath and dried in the air, after which they are placed in a very dil. soln. of HCOOH , AcOH , or some acid salt such as $\text{Al}(\text{AcO})_3$. The deposit thus formed is very adherent, stable, and waterproof, yet sufficiently permeable to air. The concn. of the bath will vary with the kind of fabric, and should be detd. by trial and a microscopic examn. of the treated goods. A military cloth known as "blue horizon" should receive the equiv. of 20 g. pptd. Al_2O_3 per meter of cloth.

L. W. RIGGS.

Various methods of modifying starch for sizing purposes. PERCY BEAN. *J. Textile Inst.* 6, 223-30(1915).—For pure sizing wheat flour is best and should be prepd. by fermentation for 3-6 months; for heavy sizing the flour is steeped with ZnCl_2 , thus retaining the gluten, which with its adhesive properties assists in fixing the china clay. By the ZnCl_2 method there is less loss through decompn. of starch, acids and offensive odors are not developed, mildew is avoided and a greater uniformity of the size is obtained. Farina (potato starch) gives a size lighter in color than flour or sago. Its

tendency to become soft on the weaver's beam is prevented by the addition of NaOH. Farina size does not stand prolonged boiling and should be prepd. fresh for each day's use. Sago will strengthen yarn more than any other starch and will stand prolonged boiling without losing strength; it should be boiled at least 2 hrs. before use. The addition of NaOH reduces the time of boiling. Size to which NaOH has been added forms a hard crust overnight, which may be prevented by covering the surface with a film of tallow to exclude the air. Tapioca is rarely used for sizing but frequently occurs as an adulterant of sago. Maize starch is cheapest and may be used for all kinds of sizing, especial care being taken that it is thoroughly gelatinized. Any method of modifying starch can only be considered successful if the starch is strengthened by the treatment.

L. W. RIGGS.

Foreign fabrics. German-made worsted cloths analyzed at the Bradford Technical College. EBER MIDGLEY. *J. Textile Inst.* 6, 212-8(1915).—Over 60 patterns were examd. as to the kind of raw materials, structure of yarns, structure of cloth, and finishing. In addition to the usual mechanical methods of finishing, chem. methods were employed to obtain improved handle, appearance, firmness and permanency of finish. Chem. analyses of the patterns by L. L. Loyd indicated the employment of starch, $MgSO_4$, sol. oil substitute, glue, and free oil emulsion in various combinations as finishing agents. In 9 patterns reported the filling did not exceed 3%. Two patterns showing 10 and 14%, resp., were regarded as adulterated by filling. Suggestions for further investigation are given in order to ascertain if German worsteds may be produced under Bradford conditions.

L. W. RIGGS.

An oxidation product of indigo blue (FRIEDLÄNDER) 10.

BRAUTMONT, R.: *The Theory and Technology of the Manufacture of Woolen, Worsted, and Union Yarns and Fabrics.* New York: Van Nostrand Co. 676 pp. \$12.00.

ZART, A.: *Farben und Farbstoffe; ihre Erzeugung und Verwendung.* Leipzig. 1 M.

Fabric for making belts, aprons or roll-coverings for textile machinery. C. W. ROYCE. U. S., 1,163,262. Dec. 7. A fabric such as woven cotton having a wool napped surface is coated with a mixt. of linseed oil, clay and pigment to give it a springy or resilient character.

Bleaching cotton, etc. R. MULLER. U. S., 1,163,438, Dec. 7. The material to be bleached is immersed in a dil. aq. soln. of NaOH, borax or other alk. compd. under 2 atm. steam pressure and air under pressure is blown through the soln. until the desired bleaching action is effected.

Mechanical method of uniting and spinning artificial silk fibers as formed. P. GIRARD and J. SONNERY. U. S., 1,164,084, Dec. 14.

Removing stains from fabrics. G. E. DARROW. U. S., 1,164,705, Dec. 21. Stains are removed from fabrics by successive treatment with a soln. of oxalic acid and SO_2 and a soln. of $Ca(OCl)_2$.

Waterproofing cord. J. E. H. HYDE. U. S., 1,165,179. Dec. 21. Cotton or other cord is treated with an adhesive waterproofing mixt. formed of acetylcellulose, dichlorohydrin, MeOH, castor oil or other non-drying fatty oil sol. in alc., amyl acetate and $MgCO_3$. The products are suitable for fish lines or nets.

Degumming fibers. J. MEISTER. Brit., 17,941, July 29, 1914. In removing gum from textile fibers by means of pancreatin and enzymic substances, the material is first treated in a dil. alk. bath containing borax and NH_4OH , and then in a second bath with a soln. containing borax, NH_4OH , and NaCl , and an enzymic prepn. such as oropon. H_2O_2 may be added. The process may be used for treating double cocoons, floss silk, perforated cocoons, tussah, and wild silks.

Damping and conditioning yarns. T. HALLIWELL. Brit., 18,573, Aug. 12, 1914. App. for damping or conditioning yarns or threads by the circulation through them of air carrying H_2O in a finely divided state.

Production of azo dyes on the fiber. AKT.-GES. FÜR ANILIN-FABRIKATION. Ger., 284,695, Jan. 1, 1914. Diazo compds. are combined with 1-nitroaryl-3-methyl-5-pyrazolones. The resulting shades are in general yellow, and very clear.

Fixing iron oxide on silk. W. BUSCHHÜTER and M. VOIGT. Ger., 284,853, Feb. 7, 1914. The fibers, treated with Fe mordant, are satd. with bast soap solns. or soap solns. with the addition of albuminoid substances or grape sugar, steamed, and washed. Satisfactory results have been secured with a soln. containing, per liter, 50 g. Marseilles soap, and 5 g. gelatin or glue.

Gray dyeings on pelts, hair, feathers, admitting of white etching. FARBW. v. M. L. & B. Ger., 284,854, Jan. 3, 1914. The material, mordanted in the usual manner with Fe salts, is dyed with nucleus-acylated pyrogallols, such as trihydroxyacetophenone.

26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

Tests on lithopone. H. A. GARDNER. *Drugs, Oils and Paints* 31, 252-3(1915).—Results of chem. analysis and practical tests on 14 samples of lithopone. The methods of testing are given. E. W. BOUGHTON.

Turpentine oil and resin of *Boswellia serrata* from India. ANON. *Bull. Imp. Inst.* 13, 351-6(1915).—Gum from *Boswellia serrata* was distd. with steam in a still with a false bottom; the volatile constituents passed off while the resin and oil passed through the false bottom. The oil was sepd. from the resin by steam distn. and the resultant oil fractionally distd. up to 155° ; a turpentine oil consisting of *d*-pinene and a second portion consisting of limonene were obtained. This turpentine closely resembles the American product in solvent power and as a drying agent. Two samples of resin were analyzed and their commercial possibilities discussed. The resin when distd. behaves differently from ordinary resin and yields a different set of products (not described). R. L. SIBLEY.

Some little known resins. ANON. *Bull. Imp. Inst.* 13, 356-75(1915).—The exudation of the euphorbias may contain over 90% of resin and only 2 or 3% of material which is either caoutchouc, or has some resemblance to that substance. Some of these resins cannot even be utilized by combining with PbO , ZnO , or MnO to form resinates for use in paint material, as they are neutral substances, and contain no resin acid. Samples of resins from 8 different species of *Euphorbia* were examd. chemically, and their soly., acid value, m. p., and sapon. value detd. R. L. SIBLEY.

DOELTER, C.: Ueber natürliches und künstliches Ultramarin. Wien: A. Hölder.

MITCHELL, C. A. AND HEPWORTH, T. C.: The Production and Properties of Printing, Writing, and Copying Inks. New ed. London: C. Griffin & Co.

Varnish, paint or printing color. N. W. TURKIN. U. S., 1,164,036, Dec. 14. A colloidal soln. of a color pigment, such as Biebrich scarlet, in a base (insol. in H_2O) formed of alizarin oil and Al acetate is mixed with a varnish containing resins, toluene and fish oil.

Heat- and acid-resisting paint. E. R. STOWELL. U. S., 1,164,670, Dec. 21. A pasty mixt. of carborundum powder and Na silicate soln. is heated to $30-40^\circ$ to hasten the generation of H which takes place by reaction of the free alkali of the silicate on free Si or Si compds. present in the carborundum; then H_2O is added to the pasty mixt. to reduce it to the desired consistency and it is packed into sealed containers, danger from generation of H in the latter being avoided by the preliminary heating.

White lead. C. WHITE and J. W. PATTERSON. U. S., 1,163,052, Dec. 7. Calined soda is added to a soln. of basic Pb acetate satd. with PbO at about boiling temp. and after pptn. of white lead has been effected $NaHCO_3$ is added to prevent discoloration of the product.

Primer for use before painting. H. M. ASHBY. U. S., 1,164,324, Dec. 14. Kauri gum, linseed oil, PbO and toluene are mixed in the proportions of 20:5:0.5:74.5 and used as a primer on wood to prevent peeling and cracking of paint. The primer is especially applicable to yellow pine or other resinous woods.

Surface for color printing. N. W. TURKIN. U. S., 1,164,037, Dec. 14. A colloidal soln. of a pigment such as Biebrich scarlet is made by heating the pigment with alizarin oil, basic Al acetate and $C_{10}H_8$ and allowing the mixt. to solidify on cooling to form a printing surface. A solvent such as toluene may be added as a softening agent.

Paint- and varnish-remover. H. BIRCHALL. U. S., 1,165,148, Dec. 21. Alc. 5 gals. is mixed with turpentine 1 gal., oil of mirbane 1 gal., $HOAc$ 2 qts., gum camphor 2 lbs. and beeswax 2 lbs.

Varnishes; coating processes. B. D. BAKER. Brit., 18,268, Aug. 7, 1914. Articles e. g., wheel rims and door handles, are coated with celluloid by first coating with a lacquer-like soln. of celluloid in a mixt. of acetone and American turpentine as by brushing or spraying, and then immersing in a viscous soln. of celluloid in acetone, amyl acetate, and American turpentine, which has preferably been allowed to stand until free from air bubbles. The withdrawal of the article from the coating-bath takes place quickly at first and slowly towards the end so that runners or beads are not formed on it as it leaves the soln. For this purpose, the soln. may be run out of the coating-bath quickly at first and then more slowly, or the articles may be lifted from the bath so as to leave the liquid in a similar manner. The proportions of the ingredients of the varnish may be varied so as to render it suitable for coating articles of metal, concrete, and other material.

Anti-fouling composition for ship hulls. W. SCHÖLLER and W. SCHRAUTH. Ger., 285,225, Dec. 10, 1913. Mercurized fats and fatty acids, especially, however, mercurized resins and resin acids, are used instead of unmercurized products, in the prepn. of spirit, oil, and varnish colors. Resin and resin acids are mercurized as specified in 228,877 (C. A. 5, 2307) for mercurizing fats, oils, and fatty acids. E. g., 5 kg. shellac dissolved in 10-15 kg. MeOH are mixed with a concd. soln. of 1 kg. $Hg(OAc)_2$ in MeOH. After standing for several hrs., Hg ions are no longer present in the soln., and after distg. off the MeOH the mercurized shellac can be recovered as resin, or the resulting soln. can be employed directly for the production of the coating mass. The mercurization of mastic, sandarac, dammar resin, colophonium, copal, etc., is effected in like manner. The oil or resin in the product may also be mercurized before mixing. E. g., 30 parts of a 50% soln. of $Hg(OAc)_2$ in MeOH are added to 100 kg. of a coating compn. con-

sisting of 30 parts MeOH, 9 parts shellac, 9 parts resin, 3 parts gallipot, 2 parts soft gallipot. Even after a few hrs. the Hg is combined and the mass is ready for use after the addition of the usual color additions (oxides, etc.).

Resin cement for tools. CHEFKA-GES. M. B. H. Ger., 284,701, Nov. 28, 1913. This product, which resists protracted boiling in H_2O , weak soda- and soap-solns., is obtained by fusing hardened resins, especially Ca resinate, the m. p. of which is considerably above 100° , or their mixts. with colophonium, with a resin as neutral as possible or difficultly saponifiable and having low m. p., and then working into the product a suitable filler, such as chalk, sand, talc, etc. The m. p. of the products can be regulated as desired, and they are not affected by protracted boiling in H_2O , soda-, soap-, or salt-solns. E. g., 100 g. colophonium are neutralized gradually with 20 g. of finely pulverized $Ca(OH)_2$ at about 180° and 20 g. gum resin and 10 g. coumaron resin are added to the mass while it is still liquid. The mixt. is heated at 200° until a test shows a m. p. of about 102° . If the m. p. is higher, it may be lowered by adding colophonium and coumaron resin, and finally stirring into the hot liquid resin mass 40 g. of a mixt. of chalk and pumice stone powder.

27. FATS, FATTY OILS AND SOAPS.

H. SCHERUBEL.

Illipe nuts and sources of Borneo tallow. ANON. *Bull. Imp. Inst.* 13, 335-44 (1915).—Four samples of nuts were analyzed and the fats, which composed from 43 to 61% of the kernel, were investigated and compared with those of other nuts. The fats most closely resemble cacao butter in analytical constants. R. L. SIBLEY.

Production and utilization of rape seed. ANON. *Bull. Imp. Inst.* 13, 452-60 (1915).—The amt. of oil in rape seed varies from 33 to 45%. The low sapon. value of the oil is due to the predominant constituent trierucin. Rapeseed cake and meal contains 33 to 38% crude proteins. The meal contains 4.9% N, 1.5% K_2O and 2.5% P_2O_5 , and forms an excellent fertilizer for wheat or barley. R. L. SIBLEY.

"Owere" seeds (*Monodora myristica*) from the Gold Coast. ANON. *Bull. Imp. Inst.* 13, 346-50 (1915).—The seeds upon steam distn. yielded 5.9% of a colorless volatile oil possessing a lemon-like odor and taste. The oil consisted largely of terpenes. The residue from the distn. yielded a quantity of fixed oil amounting to 36% of the original wt. of the seeds. This was of a dark reddish brown color. The residual meal left after the extn. of the oils contained 17.6% crude proteins and gave 80 food units. It possessed too much fiber to be used even as feeding stuff. R. L. SIBLEY.

***Madia sativa* seed from South Africa.** ANON. *Bull. Imp. Inst.* 13, 344-6 (1915).—Seeds of *Madia sativa* were found to yield 36.5% of a yellowish brown, liquid oil. This was examd. chemically. The results practically agree with figures previously given by Lewkowitsch. The residual meal had no alkaloids nor cyanogenetic glucosides and contained 7% fat, 28.2% crude proteins and an excessive amt. of fiber (24.4%). Results showed that this meal contained more food units than sun-flower seed cake or undecorticated cotton seed cake, and it may prove of value in cattle feeding.

R. L. SIBLEY.

Electricity in soap manufacture. ANON. *Elec. Rev. West. Elec.* 67, 1139-41 (1915).—Describes the process of soap making and gives a table of approximate h. p. requirements for the machines used in the industry. C. G. F.

Method of obtaining melting points (KNAPP) 7.

KOPPE, S. W.: *Glycerine: Its Production, Uses and Examination.* Trans. by W. H. Simmons. London: Scott, Greenwood & Sons. 258 pp. 7 s, 6 d.

Extracting oil from seed by steam and pressure. W. McC. NEALE. U. S., 1,164,383, Dec. 14.

Treating carcasses. F. FAHL. Brit., 18,360, Aug. 7, 1914. Carcasses and animal or fish offal are treated to ext. fats and to form a meal suitable as a food for animals or as a fertilizer, first with steam under pressure, then mechanically to sep. H_2O , and then with benzene or other spirit, and are finally dried by treatment with vapors of benzine or other spirit. Suitable app. is specified.

29. LEATHER AND GLUE.

LLOYD BALDERSTON.

History of the replacement of dung bates in the leather industry. JOHANNES PARSSLER. *Chem. Ztg.* 39, 893-5(1915). J. H. MOORE.

A study of the changes in skins during their conversion into leather. ANTON A. SCHLICHTER. *J. Am. Leather Chem. Assoc.* 10, 526-58, 585-612(1915).—(Thesis, Univ. of Mich.) Various methods of cutting sections for microscopic study were tested. S. concludes that none of the methods of imbedding in paraffin can give satisfactory sections. Dehydration with EtOH and infiltration with celloidin was found satisfactory, the whole process taking from 4 to 5 weeks. Sections as thin as 7 microns were cut. Freezing also gave good results, but the sections were 2 to 3 times as thick as with celloidin. Microscopic examn. of a skin at various stages in the process of tanning gives no certain indications that the process is going on well or the reverse. By means of special app., the vol. of pieces of skin was measured at intervals during the liming process. Results are tabulated and curves given showing changes in weight, vol. and density, these including also changes in the subsequent processes of bating, pickling and tanning. Efforts to find means for preventing thinness of flank in the finished product were fruitless. Skins sterilized by the formic-mercury process of Seymour-Jones (*C. A.* 8, 3513) were placed in sterile limes; the hair could be removed after 2 weeks or more. Tests of the sterility of the hide and of the liquor were made after the completion of the process, and the expts. seem to show that it is possible to unhair hides in sterile limes. L. B.

Japanese white leather. MAX RAY. *Shoe Leather Rep.* 120, No. 7, 27-9(1915); *J. Am. Leather Chem. Assoc.* 11, 22-5(1916).—Japanese white leather is probably the toughest leather in existence. Attempts to redress these inexpensive hides were unsuccessful. When exposed to moisture they become "pelty." The process of curing is described. J. S. ROGERS.

Waterproof sole leather. HENRY R. PROCTER. *Leather Trades' Rev.* 48, 648 (1915).—To make a waterproof vegetable sole leather, the leather must be dried at 115° to 120° F., then immersed in a waterproofing bath which is kept at as low a temp. as will keep the bath a liquid (120° to 140° F.). A suitable mixt. consists of 2 parts rosin and 1 part paraffin scale with a little tallow if the leather is too hard without it. The rosin must be melted and thoroughly mixed or it will not penetrate the leather properly. The immersion lasts until bubbles cease to come from the leather—perhaps

20 min. The bends should then be hung to drip above the hot bath, and wiped with a rag or finished in any desirable way. Other waxes may be substituted. For black leather, pitch may be added.

J. S. ROGERS.

Sole leather values. M. I. A. L. T. C. *Leather Trades' Rev.* 48, 642-4 (1915); *J. Am. Leather Chem. Assoc.* 11, 15-21 (1916).—The author gives analytical data on 4 American and on 3 English leathers. He finds that since the war began, English tanners are producing inferior leather. He suggests that the absurd demand for light colored leather should cease, that leathers should be rolled as wet as the color will stand, that more pressure might be used, and that some form of finishing as with oils and greases might help in waterproofing the leather.

J. S. ROGERS.

The tanning content of Pacific Coast conifers. H. K. BENSON AND THOS. G. THOMPSON. *J. Ind. Eng. Chem.* 7, 915-16 (1915).—The bark of the Western hemlock is thinner than that of Eastern hemlock, but it has a higher tannin content. Analyses show 14 to 17% tannin. The prepn. and extn. of samples is described in detail. Several skins were tanned in an ext. made from the fir chips from the bark and slabs. A desirable leather was produced having a color similar to that of oak-tanned leather.

J. S. ROGERS.

Decolorizing tanning extracts. G. A. KERR. U. S., 1,163,827, Dec. 14. A homogeneous paste is formed of peas, beans or other legumes by boiling with H_2O and this paste (or the fresh raw legumes) may be used to decolorize tanning exts.

Tanning materials. DEUTSCHE KOLONIALE GERB- UND FARBSTOFF-GES. M. B. H. Aust., 3,193, Apr. 4, 1914. The product is obtained by condensing 1 mol. $HCHO$ with 2 mols. of a 1- or 2-hydroxynaphthalenesulfonic acid in aq. or weakly acid soln., with prevention of elevated temps., preferably at the ordinary temp.

Tanning extracts. W. E. HORROCKS and J. K. TULLIS. Brit., 18,332, Aug. 7, 1914. A tanning ext. is produced by treating wood pulp exts. obtained as a waste or by-product in the manuf. of paper pulp or other cellulose material, in a heated condition with one or more neutral sol. salts. The ext. thus obtained, which is practically entirely sol., may be used as a liquid, paste, or powder.

Soluble tanning preparations. BADISCHE. Ger., 284,119, Oct. 17, 1912. The products are readily sol. in cold H_2O and are prepd. from tanning exts. which contain insol. or difficultly sol. constituents.

Condensation products of phenols and formaldehyde. BADISCHE. Ger., 282,850, June 27, 1913. These products, having tanning properties, as distinguished from those obtained according to 87,335, are obtained by treating aromatic hydroxy compds., or derivs. or salts of these compds.; with sulfites and $HCHO$, or agents evolving $HCHO$, under pressure and at temps. above 100° . An alk. reaction is maintained preferably to end of the condensation. E. g., 94 parts phenol (1 mol.) are heated with a concd. aq. soln. of 252 parts neutral cryst. sulfite (1 mol.) and 94 parts of a 40% soln. of $HCHO$ (1.25 mols.) in the autoclave for 8 hrs. at $140-150^\circ$.

Revoluble tanning or washing drum. BAYERISCHE MASCHINENFABRIK REGENSBURG F. J. SCHLAGETER. Ger., 284,227, Nov. 25, 1913. Cf. C. A. 9, 2466.

Softening and stretching leather. A. JOH. Ger., 284,703, July 12, 1913. A suitable machine is specified.

Flexible leather substance. L. HEIMANN. Ger., 283,673, Jan. 22, 1914. The leather is craped or crimped transversely, and a coating of gum is applied to its inner side.

Artificial leather. F. HESSER. Ger., 284,876, Oct. 21, 1913. Addition to 250,029 (C. A. 6, 3543). The process of the parent patent is modified in that, after the application of the solvent to the material, and before drying, the wet material is kept cool for some time in order to secure an intensive action of the solvent upon the binder while avoiding as much as possible the evapn. of the solvent. Between the app. for applying the solvent and that for drying is arranged a low narrow flat canal of 100–200 m. in length which is kept cool by air, which encloses the drying chamber.

Drying patent leather. C. HEYL. Ger., 284,604, Sept. 13, 1912. Artificial light is used.

Treating patent leather. C. HEYL. Ger., 284,605, Mar. 23, 1913. The drying by means of artificial light (cf. 284,604, *supra*) is improved materially by introducing some NH_3 , so that the patent leather is subjected simultaneously to the action of light and NH_3 . The acid constituents of the lacquer substance resulting from the strong oxidation due to the light action are in this manner neutralized, whereby the elasticity of the leather is greatly increased.

Ornamenting and rolling leather. C. VOSS. Ger., 284,606, Aug. 1, 1913. A machine is specified.

Sand-blasting the grain side of leather. C. RAUSCH. Ger., 284,239, Dec. 4, 1913. One or more body colors or coatings of varnish are applied to the surface of the leather and removed with the aid of a stencil or by sand blast. The depressions formed are filled with a varnish of another color.

Preserving leather. A. J. GODRON. Holl., 1,908, Jan. 13, 1913. Animal fat and resin are heated together. S is added to the mixt. and the resulting mass is allowed to cool. The resulting product is dissolved, *e. g.*, in benzene, and the leather is impregnated with this soln.

30. RUBBER AND ALLIED SUBSTANCES.

R. T. STOKES.

Isoprene from β -pinene. A. W. SCHÖRGER AND R. SAYRE. *J. Ind. Eng. Chem.* 7, 924–6(1915).—Under the same conditions turpentine and β -pinene yield about the same amount of isoprene, approx. 10%. S. and S. agree with Herty and Graham (C. A. 8, 3865) that isoprene obtained from turpentine is not due to dipentene originally present, as asserted by Harries, and advance the opinion that the isoprene results indirectly from dipentene, formed by heating pinene. It is not considered probable that either α -pinene or β -pinene can be made to yield directly sufficient isoprene for the commercial production of rubber, but as good yields are possible from dipentene, an attempt to obtain an approx. quant. conversion of pinene into dipentene is believed worthy of further consideration. The β -pinene used in the experimental work was obtained from the oleoresin of Western yellow pine. A modified Harries isoprene lamp (C. A. 5, 3583) used in this work is described in detail. RAXLEY F. WEBER.

The preparation and chemical properties of chemically pure rubber. F. HEIM AND R. MARQUIS. *Chem. Trade J.* 57, 360(1915).—H. and M. have produced pure rubber from wild Para rubber from the Amazons, coagulated by smoke, and from plantation Para rubber from Indo-China, coagulated by AcOH . They have not yet detd. whether pure rubbers of different botanical origin have identical properties. The method of prepn. of pure rubber consists of maceration, followed by washing in cold water in a tube covered with black paper, washing with acetone, evapn. of the acetone,

dissolving in ether or benzene and filtering through a Büchner porcelain filter, pptn. with alc. or acetone, digestion with alc. (to eliminate traces of benzene), and drying in the dark over H_2SO_4 . Caoutchouc thus prepd. from unsmoked rubber is perfectly white, while that from rubber coagulated by smoke is slightly yellow; the two are, however, of equal chemical purity, for the color is due to quantities of impurities too small to be measured. The pure caoutchouc is free from resin and proteins, and elementary analysis showed a compn. corresponding to $(C_5H_8)_n$, a polymer of isoprene. It behaves towards solvents like impure rubber except that its solns. are less viscous. Its chem. properties are similar to those of impure rubber; it oxidizes more readily in the air, especially when dissolved in $CHCl_3$.

EDWARD J. KELLEY.

The influence of the solvent on the viscosity of rubber solutions. F. KIRCHHOFF. *Caoutchouc gutta-percha* 12, 8649-52(1915).—K. gives the results of expts. showing (1) the relation between viscosity and rate of flow in the capillary viscosimeter, (2) the relation between viscosity and the nature of the solvent and (3) the difference in viscosity of various kinds of rubber. The coefficients of viscosity of solns. of rubber of the same concn. in the chlorinated hydrocarbons are approx. double those of benzene and benzene solns.; the viscosities of all kinds of rubber, after heating, approximate the same figure, thereby agreeing with the results obtained by Bernstein. E. J. KELLEY.

The velocity of dissolution of liquids in caoutchouc. P. BARY. *Compt. rend.* 161, 589-91(1915).—From the figures obtained by Flusin (doctorate thesis, Grenoble, 1907) on the absorption of liquids by vulcanized caoutchouc, B. deduces the formula, $p = t p_s / (A + t)$, in which p is the wt. of liquid absorbed and p_s the value for satn. The coefficient A varies with the conditions of the expt. A table is given showing the values of A and p_s for 16 different liquids.

E. W. BOUGHTON.

Vulcanization of solutions of rubber by ultraviolet rays. HELBRONNER AND BERNSTEIN. *Caoutchouc gutta-percha* 12, 8720-21(1915).—H. and B. state that vulcanization results from depolymerization of the rubber, followed by polymerization under the action of the S. This polymerization which takes place in the second phase of vulcanization is a catalytic reaction, and the combination of S with the rubber is only a secondary reaction. Solns. of rubber and S submitted to the action of ultraviolet rays were not only vulcanized, but the rubber, instead of pptg., after some time, because of its insolubility in the vulcanized state, gave a gel of remarkable stability.

EDWARD J. KELLEY.

A study of factice and its analysis. *Mat. grasses* 8, 4339-42(1915).—Compn. and methods of analysis are discussed.

EDWARD J. KELLEY.

Vulcanization experiments on plantation Para rubber. The cause of variability. B. J. EATON AND J. GRANTHAM. Dept. of Agr. Federated Malay States. *J. Soc. Chem. Ind.* 34, 989-99(1915).—The results obtained by E. and G. may be summarized as follows: (1) Considerable variation occurs in plantation Para rubbers, even in the case of "first latex" rubbers, both among rubbers from the same estate and from different estates. (2) This variation is connected principally with the behavior of the rubber on vulcanization, i. e., its rate of cure, and not in respect to its strength, elasticity, and general mechanical properties, especially in the case of properly prepd. "first latex" samples. (3) If the rate of cure be known or ascertained under spec. conditions vulcanized rubber having similar mechanical properties can be made from all good samples of "first latex" rubbers. (4) A difference in mechanical properties does exist, even among so-called first quality rubbers, but these differences are greater between high and low grade plantation rubbers; some rubbers never attain the max. mechanical properties reached by others, whatever period of cure is adopted. These differences,

in the case of "first latex" rubbers, however, are not so important to the manufacturer as the differences in rate of cure, and are not of the same order. Indeed, the remarkable uniformity in type of curve points to the fact that the variation of mechanical properties in the samples taken, at any rate, is of an accidental nature, for at points below the breaking point the mechanical properties are the same. (5) The rate of cure is affected by the presence of some non-caoutchouc substance in the latex, possible protein or some other organic constituent, or by some degradation product derived from these substances, which acts as a catalyst, and accelerates the rate of cure. (6) This substance may be already present in the latex, and its amt. in the raw rubber detd. by the mode of prepn. and coagulation; or it may be subsequently formed in the latex by decompn. and taken up by the rubber in variable quantity, according to mode of prepn.; or alternatively, it may be formed in the coagulum in variable quantity, depending on the amt. of serum (or moisture) left in the coagulum, or the presence of preservatives which hinder or prevent its formation. The alternative theories await investigation. (7) Smoking, removal of excessive serum in the washing and milling processes, and preservatives are among the artificial factors which either hinder the formation of this substance or, if it already exists in the prepd. rubber, partially destroy it. (8) The catalytic substance is probably not affected greatly by heat, since in the process of mixing and vulcanization, the rubber is subjected to relatively high temp. Whether heat destroys it or prevents its formation in the latex or freshly coagulated rubber awaits investigation. (9) The rate of cure of a rubber under specific conditions is not indicated in any way by the apparent mechanical or any other apparent properties of the raw material, hence the present methods for the valuation of rubber are worthless. (10) Other things being equal, a manufacturer probably prefers a rapidly curing rubber, since it represents economy in heat, labor, and time costs; and secondly, a rubber which cures rapidly is said to have better keeping qualities after vulcanization. (11) Uniformity between "first latex" rubbers from different estates will probably be very difficult of attainment under present methods, owing to the numerous factors involved, but should not be so difficult in the case of "first latex" rubbers from the same estate. (12) Two alternatives are suggested: (a) the issue of certificates giving correct rate of cure and mechanical properties at this cure; (b) the attainment of more uniformity by the method suggested in this paper and elsewhere, in which rubber from latex collected during a series of days forms part of one ball or block, which may be described as the method of averages.

H. B. SLUSSER.

The government inspection of rubber goods. ANON. *India Rubber J.* 50, 304 (1915).—The examn. of materials for the Brit. War Office includes analysis, mechanical, physical, and for some goods electrical tests, gaging, measuring and weighing, and visual inspection. A sample from the first delivery of each contract is submitted to chem. analysis. Some of the common reasons for rejection are porosity of rubber, insufficient or excessive vulcanization, defects due to gritty chemicals, errors in dimensions.

EDWARD J. KELLEY.

DITMAR, R.: *Die Technologie des Kautschuks*. Wien: A. Hartleben. 597 ss. 22 M.

Apparatus for smoking rubber latex and forming it into sheets. L. NORZAGARAY. U. S., 1,164,850, Dec. 21.

Non-porous rubber goods. W. E. PIPER. U. S., 1,164,860, Dec. 21. Rubber sheets such as used in forming the bottoms of shoes are formed of calendered rubber

and then are heated before vulcanization to about 55° for 36 hrs. at atm. pressure to remove occluded gases from the rubber.

Vulcanizing rubber. A. D. WARNER and R. B. PRICE. U. S., 1,163,050, Dec. 7. Preparatory to vulcanization the rubber is heated to about 100° for 1 hr., compacted under a pressure of about 25 lbs. per sq. in. and then vulcanized at a temp. of 125°.

Apparatus for vulcanizing rubber tires. J. R. GAMMETER. U. S., 1,164,639, Dec. 21.

Apparatus for vulcanizing rubber shoes, etc. J. W. ARTHUR. U. S., 1,164,054, Dec. 14.

Apparatus for reclaiming rubber waste by treatment with solvents. C. S. HELLER. U. S. reissue, 14,027, Dec. 7. Cf. U. S. original, 978,583, C. A. 5, 999.

Published by the American Chemical Society, Easton, Pa.

Entered as Second-class Matter at the Post-Office, Easton, Pa.

Communications for the Editor should be addressed to E. J. Crane, Ohio State University, Columbus, Ohio.

The Council have voted that no claims for copies lost in the mails can be allowed, unless such claim is received within "sixty days" of the date of issue, nor if due to failure to give sufficient notice of change of address. Charles L. Parsons, Secretary.

Remittances for annual membership dues or for subscriptions, changes of address, orders for subscriptions or back numbers, claims for missing numbers and all matters intended for the Proceedings should be sent to the Secretary, Charles L. Parsons, Box 303, Washington, D. C.

Secretary's Office: Box 505, Washington, D. C.
Eschenbach Printing Company, Easton, Pa.

The American Chemical Society

The Board of Directors of the American Chemical Society has fixed the following schedule of prices for its publications:

Subscription Rates

Journal American Chemical Society.....	\$ 6.00
Chemical Abstracts.....	6.00
Jour. Industrial and Engineering Chemistry.....	6.00
Two Journals to same address.....	10.20
All three Journals to same address.....	12.60

Back Numbers and Volumes

	To Members	To Non-members
Single Numbers: J. A. C. S.; J. I. E. Chem. or Chem. Abs....	0.50	0.60
Proceedings, Vol. 1 (1876); Vol. 2 (1877).....	2.00	2.50
J. Am. Chem. Soc., Vols. 1-16 inclusive, each....	4.00	5.00
J. Am. Chem. Soc., Vols. 17-37 inclusive, each....	5.00	6.00
Chem. Abs., Vol. 1, 2, 3 or 5 complete, each....	10.00	12.00
Chem. Abs., Vol. 4, 6, 7, 8 or 9 complete, each....	5.00	6.00
Index to Vols. 1-20, J. Am. Chem. Soc.....	0.50	0.75
Index to Chem. Abstracts, Vol. 1, 2, 3, 4, 5, 6 or 7.....	1.00	1.00
Jour. Ind. and Eng. Chem., Vols. 1-7.....	5.00	6.00
Foreign Postage, each Journal 75c.; Chemical Abstracts, \$1.00 a year.		

Special Discounts to Newsdealers, Libraries and Institutions of Learning

Complete sets, Vols. 1 to 35, of the Journal; Proceedings, Vols. 1 and 2, and Vols. 1 to 7 of Chemical Abstracts may be had of the Secretary.

The following numbers can be furnished only in complete sets, viz: J. Am. Chem. Soc., 17 (1895), 1 and 8; 18, 5; 19, 1; 20, 3; 22, 3.

Besides the above, the following numbers can be furnished only in complete volumes, viz: J. Am. Chem. Soc., 26, 4; 29 (1907), 4; 30 (1908), 2, 3, 4, 5, 6 and 7; 33, 3, 4 and 9; 34, 9, 10 and 11; Chemical Abstracts, 1 (1907), 3, 12, 13, 14, 15 and 16; 2 (1908), 1 and 2; 5, no numbers except 1, 4 and 6; Jour. Ind. and Eng. Chem., 1, only No. 11; 3, Nos. 3 and 12; 4, Nos. 3, 4, 5, 7 and 10; 5, No. 1.

Advance payment is required and should be made by check or money order only. Stamps not wanted.

The Council has voted that the Secretary shall honor claims for non-receipt of publications only if made within sixty days of their issue. Claimants must also directly state that the publication was not delivered at their recorded address. "Missing from files" is no proof of non-receipt.

The Society will not be responsible for loss due to change of address unless notification is received one week in advance of issue.

Members or subscribers desiring their Journals or Abstracts forwarded from an old address should always notify their Postmaster and leave necessary postage.

The names of members and subscribers, whose Journals or Chemical Abstracts cannot be delivered by the Post-Office Department, will be cut off the mailing list at once, and will not be restored until correct addresses have been furnished.

In the absence of other information, the notices of change of address received from the Post-Office Department will be considered as correct, and the mailing list changed accordingly.

All communications should be addressed to

CHARLES L. PARSONS, Secretary,
Box 505, Washington, D. C.

PATENTS

Abstracts of patents are included under the appropriate divisions of the journal: those on organic compounds, unless they pertain especially to some other division, are under Pharmaceutical Chemistry. The abstracts of U. S. patents are prepared by Earl T. Ragan, those of Canadian patents by Russell S. Smart, of Fetherstonhaugh & Smart, Ottawa (50 Queen St.), and all others by O. D. Swett. Most German patents are prepared, with permission, from the abstracts in *Chemiker-Zeitung* and Italian patents from those in *Annali di chimica applicata*. All other patents are obtained direct from the specifications.

Copies of any patent may be obtained for: United States, 5 cents, sent to the Patent Office, Washington, D. C.; French, one franc, sent to L'Imprimerie Nationale, 87 rue de Vieille du Temple, Paris; German, one mark, sent to the Patent Office, Berlin; British, eight pence, sent to Patent Office, London (extra postage outside United Kingdom); Austrian, write to the Patent Office, Vienna; Danish, write to the Patent Office, Copenhagen; Norwegian, 1 crown, Patent Office, Christiania; Swedish, 1 crown, Patent Office, Stockholm. Of Canadian patents, manuscript copies only are obtainable. They may be secured from Fetherstonhaugh & Smart, or the Commissioner of Patents direct. Estimates of cost may be obtained in advance.

In ordering a copy of a patent, the number of the patent, name of the patentee, and subject of the invention should be stated.

CHEMICAL ABSTRACTS

Vol. 10.

FEBRUARY 20, 1916.

No. 4

I. APPARATUS.

L. C. JONES.

A laboratory circulating pump. J. S. MORGAN. *J. Chem. Soc.* 107, 1710-1 (1915).—T' (see fig.) is a thermostat and J the jacket surrounding the app. To the top of J a bulb with 3 inlets is fixed, as shown. One of these inlets is connected to J, one to the water pump, and the third to the tube L, which just dips into the thermostat. Over the end of L a somewhat wider tube, fitted with a T-piece, is fixed by means of a rubber connection. This T-tube serves as a means of adjustment. By completely closing the stopcock on the T-tube, H₂O only is raised by the pump; on opening the cock, a mixt. of air and H₂O is drawn up, and when the bulb is reached this mixt. separates into H₂O, which returns through J to the thermostat, and air which passes through the pump. The device can be readily caused to maintain a flow of H₂O around most complex app. at almost any desired rate. By increasing the number of intake tubes, very large jackets may be used, and the temp. gradient becomes almost negligible. Polariscopes, barometer tubes, and any parts of an app. that project can be dealt with quickly and effectually. The pump may be constructed out of materials in every lab., and serves the same purpose as rotary pumps.

F. W. SMYTH.

Apparatus for separations (Rothe's method for iron). L. BERTIAUX. *Ann. chim. anal.* 20, 213-4 (1915).—The app. consists of 2 water-jacketed, vertical, cylindrical bulbs of 200 cc. capacity, set the one above the other, and connected with a stopcock. At the bottom there is a stopcock and at the top a funnel-stopcock. The lower bulb has a side stopcock to evacuate it. The app. is so mounted as to permit it to be shaken and turned upside down.

P. M. GIESY.

Instruments for measuring the velocity and the pressure of gases. E. STACH. *Z. Ver. deut. Ing.* 59, 832-7, 856-9 (1915).—An illustrated review.

C. G. F.

Apparatus for producing and maintaining a known mixture of sulfur dioxide and air. A. E. WELLS AND L. H. DUSCHAK. Report Selby Smelter Commission. Bur. Mines, *Bull.* 98, 192-5 (1915); cf. *C. A.* 10, 446.—By means of this app. a measured current of SO₂ was continuously supplied to a known current of air drawn into a fan, where the 2 were thoroughly mixed and discharged into a room or booth, thus giving a known concn. of SO₂. The construction and use of the meter is based upon the principle that the difference in pressure between the 2 ends of a capillary tube through which a stream of gas is flowing is a measure of the rate of flow of the gas. A regulated flow of SO₂ is conducted by the glass tube *d* (see fig.) to the capillary *a-a'*, which is joined by T-tube connections to the manometer. The difference in pressure between the 2 ends of the capillary is shown by the difference in level of the menisci *e* and *f*.

which is measured on the meter stick *b*. The capillary tube was "calibrated" by allowing the gas to flow through it for a definite period of time, and with a const. pressure difference, into a soln. containing a known vol. of standard caustic alkali or I, and detg. volumetrically the SO_2 delivered. The vol. of SO_2 delivered corresponding to 4 or 5 different pressure differences was detd. for each capillary used. In plotting the pressure differences or manometer readings, as abscissas, and the corresponding rates of flow, in cc. per min., as ordinates, the curve for each capillary was obtained; for the range of vols. delivered in the tests, this was practically a straight line. After leaving

the capillary the SO_2 was conducted by glass tubing to the intake of a direct motor-driven forge blower. The air and SO_2 mixt. was then discharged into a mixing box of No. 18 galvanized Fe, 36 in. long and 12 in. in diam., containing 11 baffles (5 in. high, 3 in. apart, arranged to zigzag the mixt.). The mixt. was then conducted through a galvanized Fe pipe 48 in. long and $3\frac{1}{4}$ in. inside diam., then through a galvanized Fe box 12 in. sq. by 18 in. long, from which the gases were discharged into the booth. The booth, 6 ft. long, 4 ft. wide, and 6 ft. high, was framed with wood and covered with a close-mesh duck cloth. At one end of the hood was a curtain flap, serving as an entrance. As the vol. of air discharged into the hood by the fan was about 110 cu. ft. per min., there was maintained an excess pressure inside the booth, which prevented pure air from diffusing inward. Six in. back from the discharge end of the $3\frac{1}{4}$ -in. pipe Pitot tubes (constructed by

the Bur. of Mines and checked against an 80-light gas meter, the measurements being made in a pipe 1.04 in. in diam.) were inserted for detg. velocity, and thus the vol. of the mixt. being discharged. The manometer used was of the U-tube type, placed on a slope of 1 in 10; this allowed a considerable movement of the manometer liquid (alc.) for a small velocity head. Records showed that for velocities up to 1800 ft. per min., by applying a factor of 0.95, the velocities calcd. from the Pitot tube readings were within 2% of the actual velocities as calcd. from the vol. measured by the gas meter. With velocities ranging between 1200 and 1800 ft. per min. the velocity in the center of the pipe was found to be 1.05 times the av. velocity. Through the baffle box and pipe, the fan discharged an av. of 112 cu. ft. of air per min. To get a mixt. of 1 part SO_2 per million parts of air, it was necessary to add 3.2 cc. of SO_2 per min. By allowing several min. to elapse after starting to blow the mixt. into the booth, the concn. of the SO_2 in the air of the booth would be within 10% of the calcd. concn. for the most dil. mixt. (1 to 5 parts per million) and within 5% for stronger mixts.

F. W. SMITHER.

Apparatus for converting sulfur dioxide to sulfur trioxide. A. E. WELLS. Report Selby Smelter Commission. Bur. Mines, *Bull.* 98, 264-5 (1915); cf. C. A. 10, 446.—A porcelain tube 2.5 cm. in diam. is placed in the center of 2 electrically heated furnaces *b* and *a* (see fig.), *b* being the preheater and *a* the conversion furnace. The furnaces are built with asbestos, and wired with Ni-Cr wire. They are heated from the 110-v. line, rheostats being placed in series to control temps. A thermocouple is inserted in *a* and connected with a galvanometer for measuring the temp.

The desired vol. of air, measured through a capillary meter, is blown in at one end of the tube and passed through the preheater. The metered vol. of SO_2 is added at the other end of the preheater, the resultant mixt. being passed through the contact mass (10 g. of asbestos wool containing 4% Pt) in the conversion furnace. The air and gas mixt. contained 7 to 10% SO_2 ; temp. of contact mass was 430–450°. The app. was constructed for producing a known amt. of SO_2 for fumigation expts. The efficiency of the conversion was detd. by the analysis of the SO_2 in the vol. discharged from the blower (used to drive the mixt. into the fumigating cabinet). A very small amt. of SO_2 in the air produces a visible fume; in cloudy weather the presence of 0.0032 g. per cu. m. (= to the conversion of 1 part of SO_2 per million parts of air) was visible at some distance.

F. W. SMITHER.

Apparatus for the culture of yeast used for the determination of various sugars by fermentation. J. TRAMBICS. Budapest. *Z. Nahr.-Genussm.* 30, 293–4(1915).—The app. consists of a small round-bottomed culture flask furnished with a side outlet tube near the bottom but slightly above the level of the yeast deposit. When in operation this tube is closed with a rubber tube, glass bead valve and glass tip similar to that employed for buret, the glass tip being immersed in EtOH to prevent the invasion of foreign organisms. One arm of a glass Y-tube is sealed into the upper part of the culture flask, the remaining 2 arms being connected respectively by means of rubber tubes containing glass bead valves with the lower ends of glass siphons leading from 2 glass bottles containing, respectively, a sterile culture medium and sterile distilled water for washing the product when the culture is completed. All the flasks mentioned are furnished with vents containing cotton filters to prevent the invasion of foreign organisms. Fresh culture medium can be introduced into the culture flask by means of the siphon and glass bead valve, the exhausted liquor being drawn off from the side tube in the culture flask. When the culture is completed the yeast may be washed with sterile water in the same manner, the yeast being finally withdrawn by tilting the culture flask until the culture flows out of the side tube. Illustrated.

Magneton theory of the structure of the atom. A. L. PARSON. *Smithsonian Inst. Pub.* 65, No. 11, 80 pp.(1915).—A discussion based on the following assumptions: (1) the atom is made up of a positive part and *magnetons*, which are ring-shaped negative charges (hitherto called electrons) having, in addition to the negative charge properties, a current circuit whose radius is estd. at 1.5×10^{-8} cm., i. e., less than the radius of the atom, but of the same order, and rotating with a peripheral velocity of the order of that of light. Their rotation is independent of any positive attracting charge. (2) The positive part of the atom is a sphere of uniform positive electrification, with the properties of an elastic solid, and with a vol. normally proportional to the number of magnetons it contains. It is surrounded by an atm. or envelope of very low charge density, which is also elastic. (3) The formation of a group of 8 as a stable configuration for magnetons over the surface of a charged sphere is demonstrated for a system of 8 magnets arranged symmetrically around a cube, and is assumed to take place in atoms contg. more than 8 magnetons as well as in those contg. 8. (4) To explain the occurrence of long periods in the periodic system, and at the same time the properties of the elements in these periods, it is necessary to assume that there is in certain cases a hindrance to the formation of a group of 8 when it is normally due. On the basis of these assumptions, P. has discussed the simple magnetic attraction between 2 magnetons, the tendency to form the "group of 8," the residual magnetic forces exerted by all the combinations of magnetons, their attractive and inducing actions, the elec. polarization set up by the extn. of a magneton and its attracting and inducing actions, the pressure and vol. relations that are possible in the positive sphere, and more particularly in the envelope of the atom. It is shown that the magnetic moment of the magneton is beyond the range of present exptl. methods to detect. A rough calcn. of the heat of dissociation of H_2 into atoms, based on the work done in this paper, gave as the most probable value 5.6×10^{11} ergs; the value found by Langmuir was 77,000 cal., or 3.2×10^{12} ergs. The paper closes with a discussion of the magnetic properties of elements and compds. E. B. MILLARD.

Application of the principle of dynamic similitude to molecular physics. W. B. HARDY. *Proc. Roy. Soc. London (A)* 92, 82-100(1915).—Mathematical. The principle is developed and applied to the case of the internal latent heat of vaporization. If temp. be proportional to the mean energy of progressive motion of the mols., the internal latent heats of dynamically corresponding states should be given by the equation $LM = aT$, where L is the latent heat, M the mol. wt., a a const., and T the temp. This equation may be used either to identify corresponding temps. or to test some assumption as to the corresponding temp. The assumption here made is that the critical states are dynamically corresponding states, and that the corresponding temps. are equal fractions of the crit. temp. The equation for internal latent heats was then found to have the form $LM + b = aT$ for normal paraffins and for certain

halogen derivs. of C_6H_6 . Subject to the correctness of the assumption, the conclusion is drawn that the potential energy of repulsive forces acting between the mols. contributes to the process of evapn. An examn. of the alternative view that corresponding temps. may be identified by the relation $LM = aT$ is deferred for the present.

E. B. MILLARD.

Relation between the thermal conductivity and the viscosity of gases with reference to their molecular complexity. J. A. POLLOCK. *J. Proc. Roy. Soc. N. S. Wales* 49, 249-52(1915).—In the equation $k = f\eta c$, expressing the thermal cond. of a gas in terms of the viscosity and specific heat, the coeff. f is a numerical factor which is approx. const. for gases of the same atomicity. This suggests a relation between f and γ , the sp. heat ratio, which can be expressed by $f = a(\gamma - 1)/\gamma^n$, where a and n are consts., or in a simplified form $f = 7.32(\gamma - 1)/\gamma^{1.3}$. Except for monoatomic gases the equation quite well represents the exptl. results if n is placed equal to unity, and this leads to the relation $m\gamma k/\eta = \text{const.}$, where m is the mol. mass. The paper is a calcn. of the values of these 2 functions and a comparison of the calcd. results with observed data on several gases, taken from existing detns. In many cases the agreement is fair; in others there is quite a wide variation. The value of f is about 1.9. Also in *Phil. Mag.* 31, 52-4(1916).

E. B. MILLARD.

Arrangement of the atoms in crystals. A. JOHNSON. *Physik. Z.* 16, 269-72 (1915).—It follows from the work of Laue and the Braggs that a crystal must have a "minimal symmetry," i. e., it must have one and only one of the 230 Schoenflies space groups. It must be identical with one of the 32 crystallographic groups of symmetry as well. A table is given of symmetry groups and space groups and the groups of minimal symetry for several substances. The atomic symmetry of a given element in different compds. is generally different. Points of resemblance and difference of the atoms are mentioned, from which some negative conclusions may be drawn. For example, the 7 O atoms of the H_2O of crystn. of $FeSO_4$ cannot be equivalent, and all of the Cl atoms in PCl_5 cannot be equivalent, for no space arrangement is possible for them which is symmetrical. The 3 O atoms of aragonite are not alike, etc.

E. B. MILLARD.

Question of electric charges smaller than the electron. HARVEY FLETCHER. *Physik. Z.* 16, 316-9(1915).—Discussion of the data in *Phys. Rev.* 4, 440(1914); cf. *C. A.* 9, 1413. From the data obtained by the Millikan oil-drop method, there is no reason to consider the existence of charges smaller than 4.78×10^{-10} e. s. u. The equations for the Brownian movement, when applied to the oil-drop data, lead to values for N and e which are in complete harmony with those derived from resistance laws.

E. B. MILLARD.

Applications of the conception of positive and negative valence. VI. The existence and the properties of "free radicals." H. S. FRY. *Univ. Cincinnati. Z. physik. Chem.* 90, 458-80(1915); cf. *C. A.* 5, 2452; 7, 2899.—Free radicals are in many respects comparable with elec. neutral atoms. The instability or reactivity of free radicals depends upon their development of positive or negative valence in consequence of loss or addition of negative electrons. In other words, free radicals can exert either an oxidizing or reducing influence. The ability to give up or to take on electrons is the property of definite atoms in the free radicals. Not only triphenylmethyl and other triarylmethyls, but also NO_2 , $Na_2N_2H_4$, $(CH_3)_4N$, and other compds., as well as certain elements, may be considered as free radicals. Many facts are brought forward in support of the conception that there exists restricted analogies between the elec. cond. of triphenylmethyl in liquid SO_2 and that of Na in liquid NH_3 . In the first case the ions are probably Ph_3C^+ and SO_2^- , and in the latter Na^+ and NH_3^- . In soln. these latter ions form the free radical $NaNH_2$. H. JERMAIN CREIGHTON.

E. B. MILLARD.

The significance of light for the stability of colloidal solutions. H. NORDENSON. Upsala. *Z. physik. Chem.* 90, 603-27(1915).—It has been found that light exerts upon metal colloids a slow coagulating influence which is similar to that of a weak electrolyte. The disperse phase (Au) undergoes no chem. change under the influence of light, the action being purely physical. The influence of light is independent of chem. changes in the dispersion medium. The influence is similar for different kinds of radiations. The influence is independent of the charge of the particles. Ultra-violet and β -rays act equally well on positive and negative particles. In all cases the light coagulation is accompanied by a decrease in the total charge of the colloid.

H. JERMAIN CREIGHTON.

The course of adsorption. O. ARENDT. *Kolloidchem. Beihefte* 7, 212-50(1915).—The influence of stirring on the adsorption of starch from a starch soln. by SrCO_3 was studied. The expts. were carried out in a special metal app. in which the intensity of the stirring could be controlled and measured and samples could be extd. for very short time intervals. The analyses of the solns. were made by means of the Lowe-Zeiss interferometer. It was found that the rate of adsorption is proportional to the rate of stirring and that the adsorption equil. at very high rate of stirring can be reached after 5 sec. For different concns. of starch solns. it was found that the % of adsorbed substance in a given time interval was the same for the same intensity of stirring. For all concns. it was found that after 2 secs. of stirring 90% of the total adsorbed substance was adsorbed. To get the influence of temp. and stirring a special glass app. was used. The temp. coeff. of the rate of adsorption was found to be very small, about 1.1. The equil. was reached more quickly at higher temp. than at lower temp. The total adsorption at lower temp. was greater than at higher temp. At greater intensity of stirring the influence of temp. was less. Expts. using powdered charcoal as adsorbent confirmed the above results with SrCO_3 . However, the equil. set in very much more slowly, due to the capillary spaces in the charcoal particles. All the curves plotted show that the course of adsorption is not changed by stirring. The character of the curves remains the same. The results of the expts. show a relatively good agreement with a formula developed by R. Marc. $(X^{(\pi+1)}/t)(2X_e^\pi + KX^\pi) = \text{const.}$, where X is the amt. of adsorbed substance for time t , X_e is the amount adsorbed when equil. is reached, π is a number greater than 1, and k is a const.

WILLIAM D. ZIMMERLI.

Very small mercury droplets. (Their mechanical and optical properties, and their electric charges.) F. EHRENHAF. *Physik. Z.* 16, 227-37(1915).—The Stokes-Cunningham law is valid for spheres as small as 10^{-8} to 10^{-9} cm., for the radius as calcd. from this law agreed with that detd. from the selective radiation of light for these particles, in case of both Hg and Au. The statement that Hg droplets slowly evap. when suspended in air (Schidlof and Karpowicz, *C. A.* 9, 2029), is quite wrong, no evidence for it being obtained in these expts. The statement that charges smaller than those of the electron are capable of independent existence (Ehrenhaft, *C. A.* 9, 411, 1000) is again made. The independent existence of charges as small as 10^{-12} e. s. u. is to be considered as proved, and no objection to the method of expt. or its significance is to be found.

E. B. MILLARD.

Theory of the capillary tube. LORD RAYLEIGH. *Engineering* 100, 553(1915).—The 2 problems which are to be solved are (1) how to allow for the wt. of the meniscus in the capillary tube, (2) to find what diam. of the large tube is required in order that elevation due to curvature of the liquid surface may be neglected. In the best exptl.

arrangement a wide and a narrow tube are connected below, and the difference in levels is measured (cf. Richards and Coombs, *C. A.* 9, 2025). The Poisson formula for correcting for the wt. of the meniscus has been confirmed and extended. An approximation formula is given: $2T/g\rho r = h + (r/3) - (0.1288r^2/h) + (0.1312r^2/h^2)$, where r is the radius of the tube, h the measured height of the meniscus above the true plane level, T the surface tension, g the acceleration of gravity, and ρ the density of the fluid; it should serve for exptl. purposes. The first 2 terms on the right correspond to the assumption of a spherical meniscus, which is sufficient when r is "small enough." It is easy to show theoretically that tubes of 2.5 or 3 cm. diam. are too narrow for the "wide tube," as found by Richards and Coombs, and the widest tube used by them (3.8 cm.) was also too small to take advantage of the achieved delicacy of reading. An approx. calcn. of the necessary diam. (not given in detail) gave 4.7 cm.

E. B. MILLARD.

Comparison of the pressure balance of Schäffer and Budenberg with the open standard gage of the Leiden Physical Laboratory between twenty and one hundred atmospheres, as a contribution to the theory of the pressure balance. C. A. CROMMELIN AND E. I. SMID. *Proc. Akad. Wetenschappen* 18, 472-83(1915).—A comparison of a pressure balance with a standard manometer up to 100 atms. The measurements showed that the sensitiveness of the pressure balance far exceeds its accuracy, so that a calibration is necessary. The "functional section" appears not to be independent of pressure.

GEORGE W. MORSEY.

Methods and apparatus used in the cryogenic laboratory. XVI. The neon cycle. H. K. ONNES. Leiden. *Proc. Akad. Wetenschappen* 18, 507-15(1915).—Previously no const. temp. bath has been available in the interval between 20 and 55° K.; by the use of Ne this interval can now, in a large measure, be covered. The purification of a quantity of Ne is described, the methods and app. used for the Ne cycle being essentially the same as previously used for He. The b. p. of Ne is about 27° K., the triple point 24.5° K.

GEORGE W. MORSEY.

The determination of the concentration of hydroxyl ions. F. FRANCIS, F. H. GRAKE AND J. W. ROCHE. *J. Chem. Soc.* 107, 1651-73(1915).—The authors describe an improvement in the method previously employed (cf. *C. A.* 7, 1351; 8, 37). By measuring the pressure of the evolved N results were obtained, for the unimolecular const., of a much higher degree of accuracy without seriously diminishing the rapidity of the method. The reaction vessel used in the previous expts. was found unsuitable for pressure measurements and a new form was designed (see fig.), equally convenient for measurements by either the old volume method or the new pressure method. The tap of the reaction app. contains a cup, *B*, of 7 to 10 cc. capacity, into which the alkali or soln. of nitrosoamine can be introduced through *F*, and this soln. can then be shut in by turning through a right angle. When desired, this cup becomes a part of the reaction chamber *A* by again turning the tap through a right angle. The tap (of considerable size) is made gas-tight by binding it into the socket with rubber bands, and using the lubricant recommended by Travers ("Study of Gases," p. 24). The reaction vessel fits into a wooden cradle which is immersed in the thermostat H₂O and shaken during the whole expt. by means of an elec. motor. The holes *E*, *E'*, in the tap enable the soln. in the cup to attain thermal equil. at the same time as the contents of the reaction chamber. A const.-vol. buret is connected to *C*, and the evolved N is collected under

atm. pressure; this pressure is only altered by raising the Hg reservoir when readings have to be taken. These readings are made as rapidly as possible, after which the pressure is at once reduced to that of the atm. to minimize the difficulty of keeping the app. gas-tight. The final, or infinity, reading was always taken after a period had elapsed equal to 10 times that required for the reaction to proceed half-way to completion. In most cases the reaction is sufficiently slow for 2 expts. to be made simultaneously; in this case, the app. is duplicated, set in the same cradle, and the 2 pressure tubes of the const.-vol. buret placed side by side on the scale, in order that readings may be taken by the same cathetometer. The whole app. may be washed out with N through *D* when the expt. is to be made in the absence of O, *e. g.*, with the nitrosoamines of vinyl- and isobutyl-diacetoneamine. The unimolecular equation, using the pressure method, is: $k = (2.303/t) \log (P_{\infty} - P_0)/(P_{\infty} - P)$, where P_0 = pressure reading at the time taken as zero, P the reading at time t (in secs.), and P_{∞} the infinity reading. The mean of 12 expts. (decompn. of nitrosotriacetoneamine by alkalis) gave for $[\text{OH}^-]$ up to 0.05 *N* the ratio k/OH^- at $30^\circ = 1.92$; max. deviation not greater than about 0.7%. An investigation of the catalysis of nitroso-vinyl- and isobutyl-diacetoneamines showed that in these cases the "drift" in the velocity consts. does not commence until $[\text{OH}^-] =$ about 0.4 *N*, enabling one to bridge that region which cannot be measured by nitrosotriacetoneamine and to use the method for measuring all values of $[\text{OH}^-]$. With these derivs. the expts. have to be made in an atm. of N; the velocity of decompn. is slower, and at lower concns. the expts. are best made at 50° (about $[\text{OH}^-] = 0.2$ *N*, 40°). The values for k/OH^- are: nitrosovinyl diacetoneamine = 0.171 at 40° , 0.553 at 50° , temp. coeff. = 3.21; nitrosoisobutyl diacetoneamine = 0.241 at 40° , 0.714 at 50° , temp. coeff. = 2.96. A redetn. of the temp. coeff. at 30° of nitrosotriacetoneamine using the ratio $k/\text{OH}^- = 1.92$ gave 2.35. In a few expts. on the hydrolysis of Na_2CO_3 , the new method gave data for $[\text{OH}^-]$ in good agreement with those deduced from cond. and *e. m. f.* measurements. Results are given and discussed on the action of neutral salts on the course of the catalysis. It is concluded that: no satisfactory explanation of the mechanism of the catalysts described is to be obtained by further kinetic measurements; there is formed some type of complex between base and nitrosoamine in concd. solns., followed probably by a decompn. in a new direction, giving phorone or analogous derivs. In dil. solns. of OH^- no evidence for this view could be obtained by cond. measurements; the cond. of the alkali was unaltered by the addition of the nitrosoamine and showed the same value before, during, and after the reaction was complete. Expts. in higher concns. are not complete. Tables, curves, and details are given.

F. W. SMITHER.

Hydrolysis of sodium phenoxides in aqueous solution. D. R. BOYD. *J. Chem. Soc.* 107, 1538-46(1915).—The exptl. method was that of Shields (*Z. physik. Chem.* 12, 167(1893)) in which the velocity of hydrolysis of MeOAc was used to measure the concn. of alkali formed. The compds. studied and their degrees of hydrolysis are guaiacol 5.58%, PhOH 5.60%, *o*-, *m*-, and *p*-cresol 7.54, 6.08, 7.27%, resp., *o*-4-xylenol 8.28, *p*-xylenol 8.37, carvacrol 8.83, *m*-6-xylenol 10.07, thymol 10.34, ψ -cumecol 10.96, and mesitol 13.83. The acidity of phenol is reduced by the introduction of alkyl groups; the alkyl is most effective in the ortho-position with respect to the OH group, slightly less effective in the para-position, and much less in the meta-position. This rule applies to dialkyl and trialkyl derivs. of PhOH as well as to the cresols. An *iso*-propyl group in the *o*-position acts much more strongly than a Me group in the same position, but there is very little difference between the effectiveness of the 2 groups when they occupy meta-positions with respect to OH. Introduction of a methoxy group in the ortho-position scarcely alters the acidity of phenol. Values of the % hydrolysis calcd. for the di- and trimethyl-substituted phenols may be calcd. from the

figures for *o*-, *m*- and *p*-placed Me groups in the case of cresols, but they are always less than those actually observed. Mesitol dissolves in an equiv. quantity of dil. NaOH in the cold to give a colorless soln., but after the dil. (0.01 *N*) Na mesityloxide soln. had been kept at 25° for an hour it showed a distinct pink color. If such a soln. is heated to boiling, it gradually becomes an intense rose, like alk. phenolphthalein, and on cooling the color is diminished in intensity, but persists for some time. The coloration again becomes strong if the soln. is boiled once more. Purifying the mesitol further did not remove this effect. Some chem. transformation accompanies the production of the red color, for if the dil. soln. is boiled until no more mesitol escapes, the red color is not destroyed, and if the soln. is concd., acidified, and extd. with Et₂O, an oily product is obtained which is not mesitol.

E. B. MILLARD.

Conductivity and viscosity of some rubidium and ammonium salts in ternary mixtures of glycerol, acetone and water at 15, 25 and 35°. P. B. DAVIS, W. S. PUTNAM AND H. C. JONES. Johns Hopkins Univ. *Z. physik. Chem.* 90, 481-509(1915).—It is evident from the cond. of the ternary solvent that H₂O and (CH₃)₂CO exert a dissociating influence upon glycerol. The decrease of the dissociation of an associated liquid through another is much greater in a ternary mixt. than in a binary mixt., and thereby the values of the cond. and fluidity are decreased. The differences between the cond. and fluidity curves in this ternary solvent are explained through the consideration of the fluidities of the three components, in the light of the hypotheses of Dutoit and Aston and of Thompson and Nernst. The temp. coeffs. of fluidity are greater than those of cond., as in the case of binary solvents. These differences are possibly due to the formation of solvents. The values for the cond. and fluidity of the solvent with the greatest glycerol content lie furthest below those calcd. from the mean values. The temp. coeffs. of cond. agree approx. with those calcd. from the mean.

H. JERMAIN CREIGHTON.

Allotropy of the ammonium halides. I. F. E. C. SCHEFFER. Amsterdam. *Proc. Akad. Wetenschappen* 18, 446-58(1915).—Certain evidence in the literature indicates the existence of 2 polymorphic forms of NH₄Cl, but the subject has never been investigated, and if such forms exist it has not been known whether they are enantiotropic or monotropic. The question is of additional interest because of the fact that Wegscheider has shown (*C. A.* 3, 603) that the existence of such polymorphic forms would account for the apparent contradiction of the laws of heterogeneous equil. observed by Johnson in the case of NH₄Cl. Heating and cooling curves made with NH₄Cl indicated that an inversion does take place between the limits 187° (heating) and 174° (cooling), but because of the sluggishness of the reaction the exact temp. could not be detd. by the thermal method. The 3-phase pressure curve for the system NH₄Cl-H₂O was detd. from 160 to 199.6°, but the accuracy was not sufficient to detect a break. The *T*—*X* curve was then detd. by the closed tube method making allowance for the H₂O in the vapor space. The results obtained lie on 2 curves; the equation of the lower temp. curve is: $-\log x = (464.5/T) - 0.5400$; that of the higher temp. curve, $-\log x = (327.8/T) - 0.2412$, in which *x* is the mol. fraction of NH₄Cl. The intersection of these curves is at 184.5°, which probably represents the inversion temp. to within a few tenths of a degree. Heating curves made in the presence of a catalyzer, *e. g.*, glycerol and mannitol, gave results in harmony with the above.

GEORGE W. MORREY.

Solution and separation of substances, especially liquid crystals. O. LEHMANN. *Ann. Physik* 47, 832-52(1915); cf. *C. A.* 8, 38, 2288, 2978, 3140.—General discussion of the subject. In general, the following forces are concerned in the sepn. of solid or liquid substances from soln.: expansive force, self-purification, cohesion or adhesion pressure and (especially in liquid crystals) the directive force, which influences the other

Chemical Abstracts.

The formation of crystals, especially mixed crystals, is not due to the fact that an't Hoff osmotic pressure exceeds the soln. pressure, but is essentially a consequence of the same forces which govern adsorption. Crystals grow on account of the presence near them of mols. which are able to add themselves to the crystal. The mols. of different polymorphic modifications of a substance and the "state of aggregation" are not identical. E. B. MILLARD.

Relative affinity of metals in non-aqueous solutions, and their reactivity in insulating media. I. JNANENDRA C. GHOSH. *J. Phys. Chem.* 19, 720-33(1915).—Expts. have been made on the sp. resistance of solns. in 8 org. solvents, and of the power of metals to displace each other from such solns. The resistances were detd. from the throw of a galvanometer in series with the soln. relative to the throw in series with a megohm box when the resistance was high, and by the usual Kohlrausch method when it was low. In nearly every case the resistance of the soln. was less than that of the solvent. The solutes were FeCl_3 , HgCl_2 , $\text{Hg}(\text{CN})_2$, CdI_2 and Pb oleate . A piece of metal was sealed up in a tube of soln. and allowed to stand for several days at room temp.; then the tube was opened and samples of the liquid analyzed. A series was obtained which was not identical with the usual e. m. f. series, for the "series" is not independent of the solvent, and the solvent present in any given combination. The velocity of the displacement may be very slow in a soln. with a sp. resistance of 500,000,000 ohms, but is never zero, and the change in velocity when passing from one solvent to another is not comparable to the change in elec. resistance. E. B. MILLARD.

Thermodynamic integrator. R. GANZ AND A. P. MIGUEZ. *Physik. Z.* 16, 247-51(1915).—Theoretical. The details of an integrator similar in construction to a pantograph have been given, and its use suggested in the calcs. in the Nernst heat theorem. E. B. MILLARD.

Graphical and mechanical calculation of chemical affinities from thermal data. W. DRÄGER. *Physik. Z.* 16, 295-8(1915); cf. preceding abstr.—Discussion of the above. E. B. MILLARD.

Electrical conductivity of certain salts in pyridine. E. X. ANDERSON. *J. Phys. Chem.* 19, 753-89(1915).—Conds. of about 6 concns. each of 15 salts in pyridine have been made by the usual method at 0, 25 and 50°, using cells of the Jones and Lindsay type (*Z. Physik. Chem.* 56, 129(1906)). The electrolytes divided themselves into 2 classes, those for which the cond. increased with diln. throughout, and those which showed minimum values of equiv. cond. The temp. coeffs. were smaller between 0 and 25° than between 25 and 50°. Polymers are thought to exist in soln., and the cond. of cond. solns. is largely due to ions from these polymers, e. g., Hg^{++} and HgCl_4^{--} in HgCl_2 . As diln. proceeds, there is more and more tendency toward the formation of simple ions; hence the mol. cond. increased. The anomalous behavior in equiv. cond. is due entirely to the presence and properties of the ionizable polymerized solute, which predominates in concd. solns. E. B. MILLARD.

Dielectric constants of some compounds of vanadium. A. G. LOOMIS AND H. J. DRAYTON. *J. Phys. Chem.* 19, 734-8(1915).—The app. was that used before (C. A. 4, 1914). V_2O_5 was mixed with sugar charcoal and ignited in a stream of H, then a stream of Cl was passed over the V_2O_5 which had been formed, and the resulting VOCl_3 was purified by distn. VOBr_3 was prepd. in a similar manner. VOCl_3 was made by passing Cl over ferro-vanadium and fractionally distg. the liquid product. The av. consts. at room temp. were, in the order above, 3.42, 3.62, 3.05. According to Thomson's rule the dielectric power of these liquids should be small.

but no expts. were made to test this statement. The elec. cond. of the liquids is very low.

E. B. MILLARD.

The boiling points of aqueous solutions of nitric acid at different pressures. II. The influence of water-retaining agents on the composition of the mixture of maximum boiling point. H. J. M. CREIGHTON AND H. G. SMITH. Swarthmore College. *J. Franklin Inst.* 180, 703-9(1915); cf. *C. A.* 9, 744.—The influence of the presence of KHSO_4 and H_2SO_4 on the b. ps. of aq. solns. of HNO_3 has been studied at different pressures. It has been found that, while the presence of KHSO_4 brings about little or no change in the compn. of the mixt. of max. b. p., additions of H_2SO_4 to aq. solns. of HNO_3 cause a decrease in the HNO_3 content of the mixt. of max. b. p., the decrease being greater the greater the amt. of acid added. Diminishing the pressure, in the case of these mixts., of HNO_3 and H_2SO_4 , has also been found to cause a slight further decrease in the HNO_3 content of the mixt. of max. b. p. The results obtained show clearly why aq. solns. of HNO_3 can be concd. to over 90% by distn. with H_2SO_4 .

H. JERMAIN CREIGHTON.

Physico-chemical studies of copper. II. E. COHEN AND W. D. HELDERMAN. *Z. physik. Chem.* 89, 638-9(1915); cf. *C. A.* 8, 2295.—In their former work C. and H. observed by dilatometric methods a transition point in Cu at 71.7° . The object of the present investigation was to det. the effect on this transition point of the previous thermal history of the metal. The sample of Cu studied before was placed in contact with CuSO_4 soln. for several days and then showed a transition point at 70.65° . Other samples, whose previous thermal history varied widely, showed transition points between 69.2° and 71.7° . Finally, a sample was prepd. which, kept at a const. temp. of 69.5° in the dilatometer, first contracted and then expanded, indicating that more than 2 allotropic forms of the metal were present.

E. H.

The action of neutral salts on the constants of chemical equilibrium. G. POMA AND G. ALBONICO. Univ. Parma. *Atti accad. Lincei* 24, I, 747-54(1915).—The mechanism which det. the peculiar property shown by neutral salts of accelerating the course of some reactions is still quite obscure. P. has, however, (cf. *C. A.* 7, 2887) detd. experimentally: (1) that the intensity of the action developed by neutral salts is in strict relation with the chem. nature of their ions and diminishes in passing from chloride to bromides to nitrates to iodides in succession; (2) that it is independent of the chem. nature of their cations; (3) that it seems to be proportional not to the complex salt concn. of the soln. but only to its ionic concn. These results show that the action of neutral salts on the velocity of reaction is not due exclusively nor mostly to the formation of hydrates in soln. P. (*C. A.* 8, 2094; 9, 991) detd. the e. m. f. and calcd. the concn. of the Cu ion in a series of aq. solns. containing a constant concn. of $\text{Cu}(\text{NO}_3)_2$ and a variable amt. of alk. earth nitrate and found, apparently contrary to the law of mass action, an increase in the Cu ions with increase in the neutral salt. The same was true for the H ion. The characteristics of this action on Cu and H are the following: (1) The intensity of this action is a function of the chem. nature of the cation; it increases with increase of the affinity for H_2O of the salt added, i. e., Rb, K, Na, Li, Ca and Mg is the order of increasing activity; (2) it is not an exclusive property of the electrolytes, for substances little ionized but with a strong affinity for H_2O (MeOH , EtOH) have the same effect on the concn. of Cu and H as the deliquescent salts; (3) with increasing diln. of the Cu the effect diminishes rapidly. P. and A. have now made a complete and systematic study of the action of neutral salts on the reaction $\text{RCO}_2\text{H} + \text{R}'\text{OH} \rightleftharpoons \text{RCO}_2\text{R}' + \text{H}_2\text{O}$ (in the presence of a strong acid) in order to det. to what extent these ideas may be applied to the study of chem. equil. The equil. const. in this case is independent of the temp., as well as the initial concns. of individual compds., which is true in spite of the fact that H_2O and alcs. are strongly associated and that

probably only the mono-mol. portion takes immediate part in the equil. If the undissociated mol. of the mineral acid or the free H ion has a purely catalytic action and if the neutral salts affect only this activity, then the catalyzers and neutral salts ought not to displace this equil. and ought to make only the proportional velocity of the 2 reactions vary. But Knoblauch (*Z. phys. Chem.* 22, 269(1897)), W. J. Jones (*C. A.* 5, 3421; 8, 3141) and F. P. Worley (*C. A.* 5, 2354; 7, 3259) have found that this is not the case. P. and A. have studied the action of neutral salts on the equil. const. in relation with the concn. of the catalyst, with the chem. nature of the organic acid esterified, with that of the esterifying alc., with the concn. of the neutral salts used and finally as a function of the mol. ratio between the amt. of H_2O and of the alc. present in the system. In each expt. H_2O and the alc. were present and in each case also either the ester or the corresponding acid besides the mineral acid catalyzer; its neutral salt was present in part of the expts. The initial concns. in $AcOH + MeOH \rightarrow H_2O + AcOMe$ are represented by a , b , c and d and k_1 and k_2 are the consts. of esterification and hydrolysis, resp. P. and A. describe a method of calcg. the values of k_1 and k_2 . The detns. of the equil. and the velocity of reaction were all made at $25^\circ \pm 0.01^\circ$ in Jena flasks provided with the Price app. to diminish the loss by evapn. The results of each expt. are given in tables. The presence of LiCl in the mixt. has an accelerating action on the velocity of esterification as well as on that of hydrolysis. Thus k_1 increases from 0.00240 to 0.00594 in the presence of 3 mols. of LiCl, while k_2 increases from 0.00041 to 0.00064, which corresponds with the diminution of the equil. const. K , which decreases from 0.170 to 0.108. It is concluded that the influence of LiCl on these reactions does not have the fundamental characteristics of the catalytic actions, but that it acts as if the neutral salt removes from the equil. part of the H_2O present in the system. II. *Ibid* 917-85. The methods and reactions studied were the same; the mol. ratio of $H_2O : MeOH = 1 : 2$ was used again and as neutral salts the chlorides of Ca, Mg and Li which have a variable affinity for H_2O . The amt. of HCl used was 0.2 mol. per l. The results show that $CaCl_2$ and $MgCl_2$ exercise an accelerating action on the velocity of esterification and hydrolysis and thus the equil. constant $K = k_1/k_2$ diminishes. With solns. containing the same number of g. mols. the displacement of the equil. increases on passing from LiCl to $CaCl_2$ to $MgCl_2$. The equil. const. in the absence of neutral salt but in the presence of 0.2 mol. HCl per l. is 0.17 which is much less than that calcd. from the results of Berthelot and P. de Saint-Gilles (*Ann. chim. phys.* 65, 66, 68 (1862-3)) which furnished a basis for the hypothesis that the HCl does not only behave as a catalyzer. Expts. showed that increasing concns. of HCl affect the equil. const. in the same way that the neutral salts do. Thus k_1 increases from 0.00240 to 0.01537 in passing from 0.2 N to 1.0 N HCl, while k_2 increases from 0.00041 to 0.00247, which confirms the view of those who maintain that the catalytic activity of the undissociated acid mols. is greater than that due to the free H ions. In order to know the influence of the chem. nature of the alc. EtOH was substituted for MeOH. The HCl was 0.2 N and the mol. ratio of $H_2O : EtOH$ was varied. For the detns. in the absence of neutral salts the difference $k_1 - k_2$ was detd. by extrapolation since the observed values diminished rapidly but seemed to tend to a limit. The cause of this diminution is not understood. The presence of LiCl, $CaCl_2$ and $MgCl_2$ in 2 N concns. has the same effect in this case as when MeOH was used. III. *Ibid* II, 43-51.—The above expts. were continued with MeOH or EtOH in various ratios with H_2O , in the presence or absence of 2 N KCl, NaCl, LiCl, $CaCl_2$ and $MgCl_2$. Expts. were made with 0.2 N HBrO, HNO_3 , HCO_2H , AcOH and $EtCO_2H$ as catalyst. The results will be referred to in the following general summary: The first general conclusion is that in the conditions used the presence of a neutral salt changes the homogeneous equil. of esterification and hydrolysis as if part of the H_2O present in the system were removed from an active role in the immediate equil. The displacement depends on the concn.

of the neutral salt used and on the nature of its cations; it increases rapidly with the diminution of the electroaffinity of the latter and thus the series increases in the order K, Na, Li, Ca and Mg. The influence of the anion is much less but not negligible; thus 2 mols. LiCl cause a diminution of 35.7% in K , 2 mols. LiBr 40%, and 2 mols. LiNO₃ 37.5%. As a whole, the results may be completely explained by assuming that the neutral salts in soln. form hydrates, the complexity of which increases with the decrease in the electroaffinity of their ions. But P. and A. consider the fact that increasing the mol. ratio between EtOH and H₂O causes a diminution in the equil. const. as constituting a grave difficulty for this hypothesis. P. (*l. c.*) studied the action of neutral salts on the apparent concns. of Cu ions and found that for the concns. studied their effects may be explained by the formation of hydrates in soln. The provisional explanation was that the equil. $\text{Cu}(\text{H}_2\text{O})_n \rightleftharpoons \text{Cu}^{+} + n\text{H}_2\text{O}$ exists in soln. and that only the anhydrous ions are active in establishing the potential difference between the Cu electrode and the soln. containing the Cu ions. The addition of a compd. capable of combining in soln. with H₂O establishes a competition between the hydrate ion and the compd. and thus increases the number of anhydrous Cu ions. All the facts observed with Cu(NO₃)₂ could be explained by this hypothesis. The analogy with what was found in the case of esterification equil. is evident. The fact that the diminution of the equil. const. and the increase of the apparent concn. of the H ion, detd. with the same quantity of neutral salt, are independent of the abs. quantity of H₂O present in the resp. systems appears difficultly reconcilable with the hypothesis that such variations may be ascribed only to the formation of hydrates in soln. In order to clear up these points the work is being continued in other directions. It was also found that the action of neutral salts on the equil. const. is influenced by the chem. nature of organic acids of the alc. esterified; in fact this const. increases rapidly with the increase of the mol. wt. of both. The accelerating action exercised by neutral salts on the single velocities of esterification and of hydrolysis as was deduced from variations of the corresponding consts. k_1 and k_2 is generally greater the greater the affinity for H₂O of the neutral salt used. This influence on the velocity of esterification is roughly proportional to the total salt concn., while its effect on the velocity of hydrolysis causes smaller increases than would be required by the law of simple proportion. The velocity of hydrolysis and that of esterification oscillate between constant values although the mol. ratio of H₂O to EtOH varies widely.

Isothermals of air, argon and helium between 0 and 200° . L. HOLBORN AND H. SCHULTZE. *Ann. Physik* 47, 1089-1111(1915).—Isothermals have been detd. at 0, 50, 100, 150 and 200° up to 75 m. Hg. The higher pressures were measured with the manometers used in former work (*C. A.* 5, 14). A flask of known vol. was filled with gas at the pressure desired for the temp. under investigation, and the gas was expanded to atm. pressure in a vessel of known vol. In this way larger and larger quantities of gas were used for the higher pressures, so that the sensitiveness of measurement remained const., in place of decreasing as is the case when a const. quantity of gas is used. Details should be obtained from the original. Discussion is reserved for a future paper.

E. B. MILLARD.

Maximum speed of vaporization of mercury. MARTIN KNUDSEN. *Ann. Physik* 47, 697-708(1915).—Assuming that none of the mols. which escape from a liquid returns to it, the speed which can be attained in evapn. is $G = \frac{1}{4} Nmc = 43.75 \times 10^{-4} p(M/T)$, where c is the mean velocity of a vapor mol., m the mass of a single mol., p the vapor pressure in dynes per sq. cm., M the mol. wt. of the vapor, and T the abs. temp. Whether this max. speed can be attained or not depends on the conditions of the evapn. The ratio between an actually observed speed of evapn. and the max. value calcd. has been detd. for Hg. It depends to a considerable extent on the condition of the surface from which the evapn. takes place, and can reach unity for an absolutely clean Hg surface. A drop of Hg was suspended in a vessel in front of an ocular microscope, the vessel was exhausted, and a side arm of it immersed in liquid air, and the rate of evapn. of the drop was detd. from measurements of the diam. made from time to time.
E. B. MILLARD.

Vapor pressure investigation of the fusion products of iodine with sulfur, selenium, and tellurium. ROBERT WRIGHT. *J. Chem. Soc.* 107, 1527-31(1915).—Weighed quantities of S and I were melted together in a tube at 180° , the mixt. cooled and broken up, and the v. p. detd. by passing a known vol. of air over it at 100° and detg. the I carried away. In other expts. the vapor pressures were detd. at 56 or 79.8° . No solid soln. was formed in any case, since there was no lowering of the vapor pressure, even when the concns. were excessive. No compds. are formed when S or Se are fused with I, but a compd. is formed with Te and I. The compn. of this compd. was detd. by fusing Te with an excess of I and removing the excess with a current of air at 100° . Its formula corresponds to TeI_4 .
E. B. MILLARD.

Interpretation of van der Waals' equation from the standpoint of volume determined by equilibrium of pressures. W. V. METCALF. *J. Phys. Chem.* 19, 705-19(1915).—In the form $p + a/v^2 = RT/(v - b)$ the equation states that external pressure (p) +

cohesive pressure (a/v^2) is equal to the elastic pressure, i. e., to $RT/(v - b)$. As necessary consequences of the kinetic interpretation of the equation, the 3 following propositions are stated: (1) vol. is detd. by an equil. of opposing pressures; (2) in the case of a stable liquid the elastic pressure, which tends to increase the vol., increases with d. more rapidly than does the cohesive pressure, which tends to decrease the vol.; (3) the difference between the d. coeffs. of these 2 pressures decreases as the d. of the liquid decreases. These 3 statements are then applied to the usual form of $V - T$ isobars, in which the first part of the curve represents the stable liquid, the part up to the max. a metastable region, from the max. to the minimum on the curve another metastable region, and from this point on the vapor condition. These points are then discussed.

E. B. MILLARD.

Ternary system: carbon tetrachloride, alcohol, water. H. A. CURTIS AND E. Y. TIRUS. *J. Phys. Chem.* 19, 738-52(1915).—Weighed amts. of H_2O and CCl_4 were stirred together in tubes in a thermostat, and alc. added from a wt. buret until the mixt. was homogeneous. From this data the equil. line between the 1-phase and 2-phase systems at 19.75° was located. The general type of the crit. soly. surface was detd. over a range of about 50° by raising and lowering the temp. of 3-component mixts. past the temp. at which turbidity occurred or disappeared. Temp. has but little effect on the mutual soly. of the 3 components. Values of n have been detd. for 8 series of mixts. As H_2O is added to mixts. of CCl_4 and alc. rich in alc., n at first increases and then decreases. With mixts. rich in CCl_4 the max. n is reached with less and less H_2O ; with mixts. containing more than 35% CCl_4 the addition of H_2O causes n to decrease continually. Expts. on the d. of mixts. showed that the vol. of the system is less than that of the components.

Electrical conduction by the oxidation of benzaldehyde and pinene. W. P. JORISSEN AND J. A. VOLLGRAFF. Leiden. *Z. physik. Chem.* 90, 553-6(1915); *Chem. Weekblad* 12, 93-7(1915).—The elec. conduction was measured by means of an electroscope. Both pinene and BzH oxidized in a stream of O rendered the O conductive.

H. JERMAIN CREIGHTON.

Determination of the true temperature of solid substances from the point of intersection of their logarithmic isochromatics in the visible spectrum. ELISABETH BENEDICT. *Ann. Physik* 47, 641-78(1915).—Detg. the point of intersection of the gray or black logarithmic isochromatics is a sensitive method of detg. the constancy of absorption of temp. radiation. From the logarithmic isochromatics for C-filament lamps, and the existence of points of intersection, it is shown that this filament and the positive crater of a C arc have const. absorption in the visible region of the spectrum, over a temp. interval of 1500 to 4200° abs. The black body in radiation measurements in the visible range may be replaced by a C filament with known surface. The normal temp. of the C arc was estd. at 4200° abs., within 1%, from these measurements. Since the gray isochromatics did not intersect for Pt, Os, and Osram lamps and the Auer mantle, these sources of light show selective radiation.

E. B. MILLARD.

Thermal and electrical conductivities of some metals between twenty and three hundred and seventy-three degrees absolute. WALTHER MEISSNER. *Ann. Physik* 47, 1001-58(1915); cf. *C. A.* 8, 2102.—Values of thermal cond. (λ) and elec. cond. (κ) have been detd. for 2 specimens of Cu (one of which was especially pure), for Au, Pt and Pb, in order to test the Lorenz law of the constancy of $\lambda/\kappa T$, and to obtain the temp. coeff. of λ . The Dieselhorst form of the Kohlrausch method was used, in which the resistance and voltage between 2 points of the specimen were detd. for 2 different current strengths, as well as the temp. coeff. of the resistance at that temp. Formulas have been derived which allow the expts. to be carried out at very low temps. At low temps. both the ratio of the Lorenz law and the values of λ undergo some varia-

tion. The correctness of the Grüneisen resistance formula was proved. On lowering the temp. from 273 to 20° abs., the ratios $\lambda/\kappa T$ and $1/\lambda$ decrease as much as 85%. The temp. change of these 2 quantities is similar to that of atomic heat. E. B. M.

Theory of the urano-uranyl sulfate photochains. G. TRÜMLER. Zürich. *Z. physik. Chem.* 90, 385-457(1915).—When current is withdrawn urano-uranyl sulfate photochains behave like ordinary elements. It has been found that the cause of the Becquerel effect lies in the uranyl salt. This effect is the manifestation of an after volume effect of light in the soln. of the uranyl salt. The potential displacement in light depends upon the chem. condition of the electrode. Although the displacement of the equil., $U^{VI} + 2A^* = U^{IV} + 2A^* + 1$, is not reversible in light, certain substances (A) exert a strong influence on the potential displacements in light, so much so, that these displacements are pushed back to a marked extent by small quantities of such substances, and under certain conditions can change their signs. Therefore, according to the compn. of the system, a positive or negative effect may result. The negative effect is diminished by I, HI, $V_2(SO_4)_3$, $VOSO_4$, HCl, $Fe_2(SO_4)_3$ and $FeSO_4$. Change of sign, is brought about by I, HI, $VOSO_4$ and $FeSO_4$, that is, the negative effect appears to be positive. The positive effect is diminished by SO_2 , $U(SO_4)_2$ and oxalic acid. The foregoing substances, which exert either a positive or negative influence on the Becquerel effect, also decrease the fluorescence of uranyl sulfate solns. The fluorescence of these solns. is also decreased by rise in temp. In conclusion a theory is put forward to explain the Becquerel effect of U salts. H. JERMAIN CREIGHTON.

Absorption spectra of aqueous solutions of hydrated salts as measured by means of the radiomicrometer. E. J. SCHAEFFER, M. G. PAULUS AND H. C. JONES. Johns Hopkins Univ. *Z. physik. Chem.* 90, 561-92(1915).—The change of the absorption bands of water due to the presence of hydrated and water-free salts has been investigated. Solns. of H_2O -free salts, which do not in themselves cause absorption, show in the center of the absorption bands less transparence than pure H_2O . On the other hand, hydrated salts, the nitrates excepted, show in aq. soln., in the center of the absorption bands, greater transparence than H_2O . It has been found that all aq. solns. of such hydrated salts are more transparent than H_2O for all the wave lengths investigated. This holds especially for the 1.25μ bands of the aq. solns. of such salts. H. J. C.

Bohr's theory of the series spectra of hydrogen and helium. EDUARD RIECKE. *Physik. Z.* 16, 222-7(1915).—Mathematical. E. B. MILLARD.

Natural optical activity of liquids and gases. M. BORN. *Physik. Z.* 16, 251-8 (1915).—Mathematics. E. B. MILLARD.

Light sensibility of copper oxide. A. H. PFUND. *Science* 42, 805-6(1915).— Cu_2O has a much lower specific resistance than either Se or stibnite and is much more transparent to red light (layers having a thickness of more than 1 mm. are still slightly translucent). The facts established for this new light-sensitive substance are: (1) the conduction is electronic and not electrolytic; (2) the increase in cond., occasioned by light, is distinctly different from that produced by a heating effect; (3) the cond. increases with the applied voltage, i. e., Ohm's law is not obeyed (voltage effect); (4) the region of increased cond. spreads slightly to portions of the material not illuminated (transmitted effect); (5) the region of highest sensibility lies in the ultraviolet near $\lambda = 2800 \text{ \AA}$; (6) cooling in liquid air increases the % change in cond. and displaces the cond. max. in the red toward shorter wave lengths; (7) the relation between the radiant energy absorbed (E) and the resultant change in cond. (C) is very approx. of the form $C = KE^b$, where K is a const., and b lies near 0.5. While the % change in cond. is much less than for Se or stibnite, the comparatively high cond. of Cu_2O makes the abs. change quite large. The best cell constructed had a resistance of 15,200

ohms at 17° for 1 v. The change of cond. occasioned by the light from a 40-watt W lamp at 20 cm. is about 15% for an exposed area of about 12 sq. mm. Details are to appear later.

E. B. MILLARD.

Optical constants of transparent silver and copper films. H. FRITZE. *Ann. Physik* 47, 763-90(1915).—Systematic study of the optical properties of films prepd. by cathodic bombardment or by chem. processes, of their relation to the thickness of the film, and to the wave length. For Ag films n decreases steadily with increasing thickness of the film from 0.6 to $105\mu\mu$, while the absorption coeff. increases, though not in the same ratio. Both quantities approach the values for the massive metal, as was shown by the Drude reflection method. The term "massive metal" may be applied to films as thin as $105\mu\mu$. Films of any thickness may show either normal or anomalous dispersion. The properties of the Ag films were independent of the method of prepn., whether from chem. reactions or cathodic decompn. The Hagen-Rubens method did not give correct results for the absorption coeff.

E. B. MILLARD.

Absorption and dispersion of light in solutions of dyes. B. J. VAN DER PLAATS. *Ann. Physik* 47, 429-62(1915).—The results of the accepted dispersion theories have been confirmed from solns. of several dyes at various concns. by expts. after the Kettler method. Values of n detd. by this interferential refractometric method are correct to 3 places. Dispersion curves calcd. from the various theories did not differ much from each other, though they all showed a smaller anomaly than the exptl. curve. The law of Beer was valid so long as there was no fluorescence.

E. B. MILLARD.

Power of reflection of some aqueous solutions in the ultra-red spectrum. F. GEHRTS. *Ann. Physik* 47, 1059-88(1915).—The reflective power of H_2O has been detd. over the range 1.0 to 11.5μ ; the results are in harmony with those of Rubens and Ladenburg, and of Ångström. The max. reflective powers of the salts in the solid state, and in soln., were, resp., $AgNO_3$ 7.45, 7.65; $CdSO_4$ 9.1, 9.25; K_2CrO_4 11.05, 11.4. Measurements with $(NH_4)_2SO_4$ and NH_4NO_3 showed that the reflective power of a soln. was not a linear function of its concn., but increased sharply with increasing concn. With the increase in concn. the reflection max. is shifted toward the short-wave end of the spectrum. Both of these facts are in harmony with the Drude theory of dispersion. The displacement of the reflection max. is due to the increase in the extinction coeff. with increasing concn. The reflection maxima for several org. substances in soln. were detd., as follows: $KSCN$ 4.95, NH_4SCN 4.95, $KCOOH$ 6.30, NH_4COOH 6.35, $NaCOOH$ 6.3, $KOAc$ 6.45, $NaOAc$ 6.5. Even in org. salts the compds. of the same acid have approx. the same reflection maxima, as shown for inorg. compds. by Coblenz, Pfund and Clark. The characteristic frequency of an org. acid radical is also shown by the esters.

E. B. MILLARD.

Doppler effect for canal rays in argon. K. FRIEDERSDORFF. *Ann. Physik* 47, 737-62(1915); cf. Stark and Kirschbaum, *C. A.* 8, 1382.—This paper covers the range 4965.4 Å to 2884.1 Å and confirms for a larger number of lines the results of S. and K. between 4300 and 4000 Å. The lines of the red A spectrum have monovalent ions as carriers, those of the blue, di- and other polyvalent ions as carriers. The number of monovalent ion carriers decreases with increasing voltage, and becomes nearly equal to zero at 42,000 volts; at 30,000 v. all of the series C and D come into emission. In A canal rays at high voltages, beside di- and tri-valent ions, there appear to be tetra-valent ions.

E. B. MILLARD.

Number of emission centers in luminous metallic vapor in flames, and the relation of this number to the brightness of the radiated spectrum lines. HERMANN SENFTLEBEN. *Ann. Physik* 47, 949-1000(1915).—The magnetic rotation of the plane of polarized light by luminous Na vapor, for the D line, was detd. as exactly as possible.

The method of crossed Nicols is not suited to exact measurements, nor is the method of quartz double wedges, but the use of Savart plates gave exact results. Voigt's theory of magnetic rotation was given support from these expts., and the number of emission centers could be calcd. from this theory with the formula $\rho = 4\pi N(e^2/m)$, where ρ is a quantity proportional to the number of centers and detd. from a complex equation connecting the rotation with the wave length, and N is the number of emission centers per unit vol. The statement of Ladenburg and Reiche that the brightness is proportional to the cube of the number of emission centers for not too small vapor densities was very exactly confirmed. This relation was also detd. for very small vapor densities, at which a direct detn. would be impossible. From the relation between brightness and the number of centers for flames of different temps. it was shown that a variation of 1.5% in the temp. changes the number of emission centers 25%. The ratio of the number of centers in the 2 D lines was detd. as 2, within a few %, and showed no variation with the vapor density or the temp. of the flame in the range investigated.

Addition to "correction of the Curie-Langevin magnetization law for molecular distances." E. A. HOLM. *Ann. Physik* 47, 694-6(1915); cf. C. A. 9, 2484. E. B. M.

Broadening of spectrum lines. A. LANDÉ. *Physik. Z.* 16, 313-6(1915).—Theoretical.

E. B. MILLARD.

Broadening of spectrum lines. A. J. DEMPSTER. *Ann. Physik* 47, 791-808 (1915).—A Hilger interferometer with Fabry-Perot plates was used to study the broadening of lines at pressures below an atm. When light is generated by electrons from a Wehnelt cathode the collisions are not elastic. The structure of a complex line is no simpler when this source is used. Over a large range of velocities the light vibrations of the electrons are equally homogeneous. In light from a quartz Hg lamp the main line is more broadened than the satellites. Broadening of the He lines is in general parallel to the Stark effect, though absorption may exert an influence. In a weak inductor-discharge the Hg green under He pressure is more broadened than would be expected from the Stark effect. The line H under He pressure is less broadened than found by Michelson under hydrogen pressure. By generating the line λ 4686 Å by rapid cathode rays it was possible to obtain a very sharp line by Rau's method, and to make an exact interferometric detn. of the wave length. The ratio of the lines to a definite at. wt. is uncertain until the cause of greater broadening of H_β and H_γ than H_α is discovered.

E. B. MILLARD.

Magnetic spectrum of oxygen canal rays. T. RETSCHINSKY. *Ann. Physik* 47, 525-62(1915).—The energy distribution of O canal rays in the magnetic field, and its relation to the discharge potential, current strength, pressure, and sign of the charge, have been detd. by the method of Wien (C. A. 4, 1934). Many maxima were found in the energy curve. It was shown by a photographic method that 3 kinds of particles were present in O canal rays under the conditions of these expts.: simple charged mols., simple charged atoms whose velocity was $\sqrt{2}$ times that of the mols., and simple charged atoms whose velocity was equal to that of the mols. Positively and negatively charged particles have corresponding velocities, but different distributions of energy among the 3 kinds of particles. The number of slow atoms is greater than that of rapidly moving atoms or mols. The velocity of the particles increases as the $1/2$ power of the discharge potential. By increasing the pressure in the discharge tube, or by decreasing the potential, the energy of the slow positive ions is decreased more than that of the rapidly moving ions.

Color effects of positive and of cathode rays in residual air, hydrogen, helium, etc. CHAS. T. KNIPP. Univ. Illinois. *Science* 42, 942-3(1915).—A description is given of an app. which is suitable for exhibiting the color effects produced by the positive and by the cathode rays in different gases. The discharge tube is dumb-bell shaped and is made of two 2-l. Florence flasks. The cathode is mounted in the neck joining the flasks and consists of a hollow Al cylinder closed at the ends with Al discs, through the center of each of which is a rectangular opening. The anode is placed in one of the bulbs. In a side tube placed at right angles to the neck of the bulbs are attached the cathode terminal, a nipple for exhausting, and a charcoal bulb for absorbing traces of air. When the proper amt. of a gas is placed in the app. according to the method described, the cathode beam will be found to give rise to one color in one of the bulbs, while in the other bulb the positive ray beam will be found to give rise to an entirely different color in the same gas. W. H. Ross.

Volatilization of extremely thin radioactive deposits. A. B. WOOD. Univ. Liverpool. *Proc. Roy. Soc. London (A)* 91, 543-60(1915).—An exptl. study was made of the more important factors which influence the volatilization of extremely thin films of the radioactive deposits. Each of the sources of influence was considered separately by eliminating as far as possible the disturbing effects of the others. Th B was chosen for the expt. as being typical of all similar constituents in the active deposits of Ra, Th or Act. Pt and quartz are recommended as the most suitable materials for forming a surface on which to collect the deposit in expts. of this kind. It was shown to be extremely difficult, however, to remove by heating alone the last traces of the active deposit from the surfaces of these as well as of other materials. This would indicate that a certain fraction of the mols. of the active deposit is held to the surface of the material on which it is deposited by forces of cohesion due to the mols. of the material in their immediate neighborhood, and it is considered possible that this small percentage of the active deposit has penetrated below the surface mols. of the material by the process of radioactive recoil. The most consistent results are obtained when the surface is exposed to the Em without elec. field, in which case the volatilization is independent of the time of exposure to the Em. The volatilization is shown to obey practically the same law as the rate of emission of positive ions from a hot body, this expression, $\text{rate} = AT^n e^{-B/T}$, being modified by the introduction of a factor $\phi(N)$ which depends on the amt. of active deposit which has been volatilized. A comparison of the volatilization curves at pressures of 760 mm. and 3 mm. showed a lowering by about 50° of the initial temp. of volatilization at low pressure. The volatilization curve at atm. pressure agrees extremely well with that given in a previous paper by Baratt and Wood (*C. A.* 8, 3530). W. H. Ross.

The variation of the potential in Röntgen tubes. A. WEHNELT. *Ann. Physik* 47, 1112-26(1915).—The deflections of the cathode ray spot of a Braun tube, connected as a condenser in parallel with a Röntgen ray tube, were photographed by means of a revolving mirror, and showed that the voltage on the tube increases to a max., when an abrupt partial discharge takes place, giving a heavy current through the tube. The voltage drops and builds up again more slowly to the discharging point, this occurring several times for each phase of the current from the induction coil. A hard tube shows only one or two such discharges per phase; a soft one has more, and when heavy currents are used there is a diminution in the abruptness of the discharge. The values of di/dt , and therefore of the voltage, are high. G. L. WENDT.

The velocity of electrons expelled by X-rays. C. G. BARKLA AND G. SHEARER. Univ. Edinburgh. *Phil. Mag.* 30, 745-53(1915).—The max. velocity of the electrons ejected from various substances on radiation with X-rays does not vary with the radiator, as is the case when ultraviolet light is used, but is within 2% the same for all substances studied. There is no notable difference in the velocities of the electrons arising from K and from L radiation. G. L. WENDT.

A method of finding the coefficients of absorption of the different constituents of a beam of heterogeneous Röntgen rays, or the periods and coefficients of damping of a vibrating dynamical system. SIR J. J. THOMSON. *Phil. Mag.* 30, 780-3(1915).—A mathematical paper. G. L. WENDT.

A comparison of the positive rays with the spectrum of the positive column in a mixture of helium and hydrogen. HAROLD SMITH. Cambridge. *Phil. Mag.* 30, 805-11(1915).—Photographs of the spectrum of the positive column, compared with the deflection curves of the positive rays in the same discharge tube, show no correspondence. A gas whose spectrum is completely masked by that of another gas present may yet take a large part in the carrying of the current in the dark space. It is suggested that, since it is the atoms of high at. wt. that effect the masking and these also tend to become multiply charged, the masking effect is due to the increased attraction and recombination of these multiply charged heavy atoms. G. L. WENDT.

The recoil of radium D from radium C. A. B. WOOD AND W. MAKOWER. Univ. Manchester. *Phil. Mag.* 30, 811-5(1915).—The α -rays from a strong deposit of Ra C on a Pt wire were passed through a narrow slit to impinge on a Schumann plate and were deflected by a magnetic field of 13,000 gauss. About half-way between the deflected and undeflected lines appeared a fainter somewhat diffuse line due to the recoiled atoms of Ra D which therefore carry a single positive charge. The diffuseness is attributed to the varying depths beneath the surface of the Pt at which the Ra C disintegrates after its formation from Ra B which enters the Pt by recoil from Ra A. G. L. WENDT.

The variation of the emanation content of certain springs. R. R. RAMSEY. Indiana Univ. *Phil. Mag.* 30, 815-8(1915).—Measurements of the Em content of the Hottle and of the Illinois Central springs at Bloomington, Ind., made weekly, from Sept. 1914 to June 1915, using the Schmidt shaking method and Em electroscope, show a variation between 445×10^{-12} and 1420×10^{-12} curies per l. in the case of the former, and between zero and 820×10^{-12} curies per l. for the latter. The Em content increased with the flow of the springs and the maxima came during the wet season. This indicates the soln. of the Em by the water percolating through the soil. G. L. WENDT.

Energy measurements of Röntgen rays. B. WINAVER AND ST. SACHS. Frankfurt a/M. *Physik. Z.* 16, 258-64(1915).—The present photographic and luminescent screen methods of detg. the radiation from an X-ray tube are far from

satisfactory. It appears desirable to devise a method utilizing the ionization produced, as in γ -ray measurements with Ra. In attempting a direct comparison of the energy from an X-ray tube with that from a known Ra prepn., in order to det. the Ra equiv. of the former, 2 factors must be dealt with particularly: the secondary radiation, and the difference in absorption of γ -rays and X-rays. The secondary radiation from γ -rays is much more penetrating than that from X-rays; hence it is proposed to reduce all secondary radiation to a minimum by employing a so-called "air electro-scope" with extremely thin walls, which Eve (C. A. 6, 26) first devised to minimize the vol. effect of the walls in producing secondary radiation. Such an electro-scope was made of thin paper walls rendered conducting by covering with lead pencil, with metallic bronze paint, or with very thin Al foil. By comparing the ionizations in this electro-scope and in an ordinary Pb electro-scope by means of a soft X-ray tube at 180 cm. distance, and 1.2 mg. of Ra at 40-50 cm., reduction factors were obtained for detg. the Ra equiv. of an X-ray tube with the Pb electro-scope. The equivs. thus detd. agree with those calcd. from the heat effects found bolometrically. A new unit of X-radiation is proposed according to which the ionization produced by the complete absorption in air of 1 unit shall be equal to the ionization produced by the complete absorption in air of the γ -rays from 1 g. of Ra in equil. with its products, Ra B and Ra C.

S. C. LIND.

A possible relation between the velocities of alpha rays and the quantum hypothesis. H. RAUSCH V. TRAUBENBERG. *Physik. Z.* 16, 264-5 (1915).—v. T. has shown (*Nachr. kgl. Ges. Göttingen* 1915) that by combining Bohr's two equations, $mv^2/r = eE/r^2$ and $mvr = h/2\pi$, the following expression is obtained for the initial velocity of β -particles: $v = (2\pi/h)eE$ in which h , the const. of the quantum hypothesis, $= 6.55 \times 10^{-27}$, e , the elemental charge, $= 4.76 \times 10^{-10}$ e. s., and E , the charge on the nucleus of the atom, $= 1/2$ at. wt.; it is assumed that the velocity of emission is the same as that of rotation about the nucleus as calcd. from the equation given above. The agreement of the calcd. with the measured velocities was satisfactory. On attempting to treat the velocities of α -particles similarly, assuming 3 electrons attached to the rotating atom, the calcd. velocities were about 10-fold too high. v. T. now makes a new assumption that the α -particle just before emission occupies a position on the equatorial belt of the parent atom which is revolving on its own axis with a velocity equal to the initial velocity of projection of the α -particle. The velocity of revolution is calcd. from the equation, $v = (9/4)(hc^2/\pi E^2)$, from which the initial velocity of α -particles from Ra C is calcd. to be 1.63×10^9 cm. sec.⁻¹, while the measured is 2.08×10^9 ; and from U₁, 1.31×10^9 cm. sec.⁻¹ as against 1.45×10^9 found by measurement, from which it is seen that the formula at least gives the order of magnitude of the velocity and also expresses the fact that the velocity increases for progressive disintegration members, without throwing any light however on the exceptions presented by Ra F and Th C₁.

S. C. LIND.

The beta rays from radium D and the absorption law for beta rays. L. MEITNER. Berlin-Dahlem. *Physik. Z.* 16, 272-6 (1915).—The existing value of 130 cm.⁻¹ for the absorption coeff. in Al of β -rays from Ra D was suspected of being greatly in error. The difficulty encountered in dealing with these rays is due to their extremely low penetrating power, which is even less than that of α -particles. This fact combined with the very high ionizing power of the latter necessitates a very complete sepn. of Ra D from Po. This was accomplished by dissolving the Pb containing Ra D in dil. HNO₃ to which a small quantity of tellurous acid was added. The Te was pptd. by SnCl₂. The Po was removed with the Te and the filtrate was repeatedly treated thus, until free from Po. A sulfide pptn. was then produced in this filtrate and a sepn. of Pb and Sn was accomplished by means of (NH₄)₂S_x. The small quantity of Pb con-

taining Ra D was dissolved in HNO_3 to which a little FeCl_3 was added and partially pptd. with NH_3 to remove Ra E. This operation was repeated until an inactive Fe ppt. was obtained. The Pb and Ra D pptd. from the last filtrate were used for the electroscopic measurements. The growth of activity due to β -rays of Ra E gave additional evidence of the purity of the Ra D initially. The 2 sets of β -rays have velocities of 0.33 and 0.39 of that of light, resp., and are the slowest β -rays which have yet been examd. electroscopically. The value of the absorption coeff. in Al is in round numbers 5500 cm^{-1} . Evidence was also obtained supporting the "complete arrest" theory of absorption of β -rays as opposed to the gradual loss of velocity from successive mol. encounters.

S. C. LIND.

The applicability of selenium to Röntgen ray energy measurements. R. FÜRSTENAU. *Physik. Z.* 16, 276-9(1915).—Remarks upon a paper of the same title by Voltz (*C. A.* 9, 3027). F. attributes the irregularities in the resistance curves of Se obtained by V. to the lag effect of the type of cell used, so that the after-effect of the previous measurement produced an error in the following one. The current loads used by V. were also excessive and were probably in part responsible for the irregular results. By suitable choice in the method of preparing the cell, F. claims that a type may be made which is distinguished by the absolute regularity of its action and which is particularly well suited to energy measurements of X-rays.

S. C. LIND.

The applicability of selenium to Röntgen ray energy measurements. F. VOLTZ. *Physik. Z.* 16, 308-11(1915).—Reply to Fürstenau (cf. preceding abstract). Even if the lag effect of a Se cell can be eliminated by suitable construction, V. remains of the opinion that selective absorption will still render the Se cell unsuitable for energy measurements of X-rays, if the primary cause of the resistance effect is attributable to the kinetic energy of the electrons produced in Se by the action of X-rays. Since this energy will vary with the conditions of operation of the X-ray tube it must still be reckoned as a disturbing source of error, a demonstration of which the author hopes to be able to furnish in the near future. The cell type constructed by Fürstenau may prove very valuable, however, for other measurements, particularly with ultraviolet light.

S. C. LIND.

The question of the measurement of the hardness of Röntgen rays photographically. F. VOLTZ. *Physik. Z.* 16, 306-8(1915).—V. finds that the results obtained in the detn. of the hardness of X-rays by photographic methods are influenced by the material of the plate as well as by the compn. of the developer. Previous results based on this method, therefore, which have been very common in medical work, are subject to criticism, and in the future the method should be abandoned except for purposes of preliminary orientation.

S. C. LIND.

Stereoscopic photography by Röntgen rays. P. KNIPPING. Charlottenburg. *Physik. Z.* 16, 280-2(1915).—Note upon the publication of Alexander (*C. A.* 9, 2485) under the same title. K. claims that X-rays played no role in the stereoscopic effects obtained by Alexander in making X-ray photographs of rolls of wire gauze. The same effects may be obtained by photographs with ordinary light under suitable conditions. Photographs are shown illustrating this contention.

S. C. LIND.

Extraction and recovery of radium, uranium and vanadium from carnotite. C. L. PARSONS, R. B. MOORE, S. C. LIND AND O. C. SCHAEFER. U. S. Bur. of Mines, *Bull.* 104, 124 pp.(1915).—A method of treatment of carnotite for the recovery of Ra, U and V has been devised in the Section of Mineral Technology in the U. S. Bur. of Mines, and in coöperation with the National Radium Inst. a plant has been constructed in Denver with a daily capacity of 3.5 tons of ore. Using this method, over 700 tons of ore had been treated up to Sept. 15, 1915, the results of which are reported

in this bulletin. The ore was mined under supervision of the Bureau in Long Park in the Paradox Valley region, Colo., and has averaged 2.66% U_3O_8 and 4.28% V_2O_5 . The Ra content has been shown to be in the theoretical equil. ratio with U and therefore averaged 7.5 parts of Ra per billion parts of ore by wt. The ore is ground for treatment to pass 20-mesh and is then extd. in earthenware pots with hot 38% HNO_3 . 500 lbs. of ore are introduced into the hot acid in each pot. 121 lbs. of 100% HNO_3 are diluted with distd. water to 38% and heated by means of live steam to about 85° before the introduction of the ore begins. Condensation of the steam lowers the concn. to 35% or less. The heat of reaction on adding the ore raises the temp. to about 92°. The heating is continued for about 15 min. after all the ore is added, and the acid soln. of Ra, V, U and other sol. bases is then dropped onto an earthenware suction filter and is filtered through asbestos cloth or filterose. The ore residue is washed once with hot HNO_3 diluted 3-fold from the original, and once with hot distd. water and is then discarded. The residue is mainly silica, should be quite light in color and does not retain more than 2-3% of Ra and about the same proportion of U. The total sol. portion of the ore is about 15%. The V extn. with HNO_3 is not very satisfactory owing to the tendency of V_2O_5 to be pptd. out by the oxidizing action. The filtrate from the extn. and the 2 washes are brought together from a number of pots into a wooden tank and are first diluted 2-3-fold with cold tap water. Since about $\frac{1}{2}$ of the original acid is still present, it is necessary to neutralize this as far as possible with NaOH until pptn. of Fe or V is just on the point of taking place. This partial neutralization still leaves about $\frac{1}{4}$ of the original acid unneutralized, but this point must not be exceeded or the Fe and V will contaminate the Ra- $BaSO_4$ ppt. Fifty lbs. of concd. H_2SO_4 and 5 lbs. of $BaCl_2$ are now added; these are sufficient together with the Ba in the ore to produce 15-20 lbs. of $BaSO_4$. The whole is pumped up, during continued agitation, through a "duriron" pump into a large wooden settling tank provided with a conical bottom into which the Ra- $BaSO_4$ ppt. is allowed to settle for 2-4 days. On the 2nd day 1 lb. of $BaCl_2$ is added in the settling tank to furnish new pptn. nuclei for the $RaSO_4$. After settling the supernatant liquid is syphoned off through a floating syphon which automatically interrupts the flow so as to leave enough liquid above the ppt. in the conical bottom to avoid disturbing the ppt. which is then brought down together with the rest of the liquid onto a large suction filter. After filtering, the Ra- $BaSO_4$ is washed once with dil. NaOH and once with H_2O , and is then collected by hand in Fe drying pans in which it is weighed after drying in steam closets. The recovery of Ra as sulfate is checked up by car-load lots of ore by making composites of ore and corresponding sulfates from each day's run; in these the Ra is detd. by the Em method. The recovery of Ra as sulfate was 88.3% for the 1st 21 cars of ore, representing a recovery of 4258 mg. of Ra element in the form of sulfate, averaging 1.08 mg. of Ra per kg. The $BaSO_4$ itself was a high grade sulfate containing little SiO_2 and running 90% pure, which constitutes a great advantage in that carbon reduction can be directly applied. For a time second sulfates were also recovered from the filtrate, this adding about 2-3% to the total Ra recovery, but since these sulfates contain only 0.07 mg. of Ra per kg., it appeared doubtful if their concn. would prove profitable and such collection was abandoned after the 14th car. The conversion of Ra- $BaSO_4$ into sol. form was accomplished by mixing with $\frac{1}{4}$ its wt. of charcoal in a ball mill and then heating for 7-10 hrs. in an oil furnace at 800°; this reduced 90% or more of Ra and Ba, in the same proportion, to the sulfide which was dissolved in excess of HCl and filtered. The undissolved residue is reserved for the same treatment, while the acid soln. is subjected to fractional crystn. in acid-proof enamel iron ware to concentrate the $RaCl_2$. After 3 crystns. at the plant, a crude chloride is delivered at the lab. containing 4-10 parts per million of Ra; this is redissolved in HCl

soln., filtered and recrystd. 3 times as chloride and is then rendered ammoniacal for the pptn. of Pb with H_2S ; the filtrate is treated with excess of $(NH_4)_2CO_3$, the ppt. of Ra- $BaCO_3$ is taken up in HBr and the recrystn. continued as bromide in acid soln., in fused quartz ware, to any desired degree of purity. The refining necessarily lags in point of time somewhat behind the production of Ra as sulfate. Up to Sept. 15, 1915, 1947.5 mg. of Ra element had been delivered to the National Radium Inst. as high grade bromide or chloride 10-90% pure, as desired. For the various methods of Ra measurement employed see Lind, *C. A.* 9, 1714; 10, 147. The filtrate from the original Ra- $BaSO_4$ pptn. which contains the V and U is run into a wooden tank containing a hot soln. of excess of Na_2CO_3 to ppt. the Fe and other bases; these are filtered off in presses and discarded. In the filtrate the U is pptd. as $Na_2U_2O_7$ by NaOH in boiling soln. The recovery of U in this form has been from 75 to 94%, averaging 84.4%. Several preliminary methods of freeing the uranate from V and of converting it into the oxide UO_2 are described but the method finally adopted is reserved for future publication. The alk. filtrate from the U is rendered neutral or very slightly acid and V is pptd. as ferrous vanadate of variable compn. containing 35-40% of V_2O_5 . The final recovery of V is very poor owing to the use of HNO_3 as original extg. acid, but since HNO_3 proved preferable for Ra, V had to be sacrificed to a final recovery of not more than 30%. The av. cost of producing 1 g. of Ra element is estd. at \$37,599; this will be further lowered on deducting the returns from the sale of the U and V by-products. The av. cost of producing 1 lb. of $Na_2U_2O_7$ has been 31.49 cents and of V_2O_5 59.1 cents in the form of ferrous vanadate. $NaNO_2$ was crystd. from the final liquors containing it and utilized to regenerate HNO_3 in a plant having a capacity of 3250 lbs. of acid daily which averaged 63%. Detailed costs of construction, equipment, operation including coöperation of the Bur. of Mines are presented and have been included in estg. final costs. A more detailed abstract of this bulletin is to be found in *J. Ind. Eng. Chem.* 8, 48-53(1916).

Radioactive liquids and gases. H. FARJAS. *Brit.*, 18,807, Aug. 18, 1914. Liquids are rendered radioactive by storing them in a vessel filled with radioactive balls prepd. according to 14,530, 1913 (*C. A.* 9, 22). Inlet and outlet cocks are fitted to the vessel. When a continuous supply of liquid is required, the app. comprizes a tube filled with the radioactive balls and provided with suitably placed end cocks. An app. for rendering air radioactive comprizes a cylinder through which a fan forces a current of air, and perforated plates placed across the cylinder and enclosing radioactive balls as before, one plate being removable.

Radioactive bodies. H. FARJAS. *Brit.*, 18,808, Aug. 18, 1914. Radioactive balls are made from mixts. of Ra ores or concentrates and cement according to 14,530, 1913 (*C. A.* 9, 22), and are formed with plain smooth surfaces without cavities, passages, or recesses.

Device for detecting loss of emanations. R. SOMMER. *Ger.*, 284,648, May 28, 1913. The device is used in connection with app. for satg. moisture with emanations.

Röntgen tubes. VEIPA-WERKE and F. DESAUER. *Ger.*, 283,858, Feb. 11, 1914.

Control of Röntgen apparatus. SIEMENS & HALSKER, ART.-GMS. *Ger.*, 285,405, Oct. 3, 1913.

Making Röntgen pictures. G. BUCKY. *Ger.*, 284,371, Feb. 6, 1913. The fogging action of secondary Röntgen rays is prevented.

4. ELECTROCHEMISTRY.

COLIN G. FINK.

Trygve D. Yensen. ANON. *Elec. World* 67, 165(1916), illus.—A biographical sketch. C. G. F.

Electrochemistry in 1914. K. ARNDT. *Chem. Ind.* 38, 242-51, 291-307(1915); cf. *C. A.* 9, 1718.—A review. F. W. SMITH.

Electric steel direct from ore fines. A. C. DALTON. *Iron Age* 96, 1184-5(1915).—Exptl. results of smelting finely pulverized (200-mesh) Moose Mt. magnetite show recovery as high as 97.1%. Anthracite screenings contain less S and cause better reduction than coke breeze. The fuel is coarse enough to allow some C to reach the bath in solid form. Excess C is largely consumed by use of natural draft through the tuyères. The lower the C content of the pig steel, the higher is the % of FeO in the slag. Control of slag must be balanced with phys. conditions, or erratic results will follow. A thin hot slag is best. Results already obtained tend to show that final costs will be within commercial limits and that the pig steel will be of high grade and uniform compn. W. H. B.

Progress in electroplating in 1914. K. NEUKAM. *Z. angew. Chem.* 28, 452-5, 463-7(1915). E. H.

Electrolytic precipitation of gold, silver and copper from cyanide solutions. G. H. CLEVINGER. *Met. Chem. Eng.* 13, 803-6, 852-60(1915).—A paper presented at the 28th general meeting of the Am. Electrochem. Soc. (San Francisco). Among the processes described are the Siemens & Halske process on the Rand, S. Africa; the practice at Minas Prietas, Mexico; San Sebastian, Salvador; Virginia City, Nevada; El Rayo, Mexico; and Nelson, Brit. Columbia. C. also discusses the relative merits of different kinds of anodes, cathodes, the treatment of by-products and the cost of installation of electrolytic pptn. plants. Full details of the various practices are given. C. A. N.

Copper cyanide solutions. W. H. WEBER. *Metal Ind.* 13, 493-4(1915); cf. *C. A.* 9, 1151.—W. compares results with CuCO_3 and CuCN dissolved in NaCN . There are secondary reactions when CuCO_3 is the Cu salt. The oxide formed at the electrode is probably Cu(OH) . $2\text{CuO} \cdot \text{Ba(CN)}_2$ is used to remove hydroxides and carbonates. From analysis the amt. of Ba(CN)_2 or other cyanide necessary to ppt. these is calcd. from the difference between total Na and Na required for NaCN and NaCu(CN)_2 in soln. W. H. BOYNTON.

A modern acid-dipping, electroplating and japanning plant. H. N. TURNBULL. *Gen. Elec. Rev.* 18, 1121-6(1915).—An illus. description of a part of the switchboard department of the General Elec. Co. The plant is divided into 3 rooms for the 3 operations. Splendid ventilation and working conditions are obtained. No hot plating solns. are used. H_2O for plating baths is distd. and that for cleaning is filtered. The cleaning soln. is agitated by admission of compressed air through a perforated pipe at the bottom of the tank. The bake oven is heated electrically and revolves. The turntable may be revolved so that one compartment is at the baking temp. (260°) while the other is in a position for loading and unloading or by turning 90° instead of 180° both will be in the baking zone. Heat is conserved by having 2 vertical doors or flaps along the edges of the oven opening; these press against the revolving cylinder and shut off from the outer air the zone between the oven and the cylinder. Advantages of the revolving oven are continuous baking, no fire risk, and economy of floor space. W. H. BOYNTON.

The installation and working of lead storage batteries. R. RANKIN. *Elec. Rev. West. Elec.* 67, 1107-8(1915); *Electrician* 76, 175(1915).—The charging plant should be large enough to charge the whole battery thoroughly. Also a means should be furnished for charging individually cells lower in condition than the rest of the battery;

this is done by a bridging-lead, or "milking booster." With the first, the "sick" cell is taken out of circuit during discharge and reinserted on charging while with the "milking booster" it may be connected during charge or discharge. The rate of charge is $\frac{1}{2}$ the usual charge rate and continuous, if possible. The temp. of the electrolyte should not be above 38°. For the first few hours the sp. gr. falls; then it gains till the whole of the sulfate is reduced. Constancy of voltage and sp. gr. indicate a full charge. If the level of the electrolyte is below the top of the plates, there is less active plate area available and corrosion results on the plate. Water is added through a tube reaching to the bottom of the cell to insure proper mixing. W. H. BOYNTON.

Effects of electrolysis on engineering structures. A. F. GANZ. San Francisco Eng. Congress. *Electrician* 76, 199-201(1915).—An explanation is given of the way in which electrolysis is caused by stray currents from electric railways with earthed return. Various means are discussed of averting electrolytic corrosion of railway tracks and their supports, sheathed cables, pipes, steel foundations, and reinforced concrete structures. F. W. SMITHER.

Tungsten arc lamps. E. A. GIMINGHAM AND S. R. MULLARD. *Elec. Rev.* 77, 743-5(1915); *Elec. World* 67, 52(1916); *Electrician* 76, 390-2(1915); *Elec. Rev. West. Elec.* 67, 1166(1915).—An arc lamp between W electrodes in an inert gas, such as N or A, is described. To start the lamps, an incandescent filament composed of W combined with ZrO_2 , ThO_2 , or the like is used. The refractory oxides are added to increase the ionizing properties. Cutout mechanism is provided to throw in the arc at the proper time. At the sputtering point 3.33 c. p. per watt is obtained. Lamps with a life of 500 hrs. have been made. The av. decrease in c. p. is 10% during life. The arc is shown to be very stable as a drop of 20 to 25% in voltage was necessary before the arc was extinguished. The range of intrinsic brilliancy between these points is 400 c. p. to 30,000 c. p. per sq. in. A stereoptican W arc lamp has recently been put on the market in London by the Edison and Swan Co. W. K. RUDER.

Solution of smoke, fume and dust problems by electrical precipitation. L. BRADLEY. *Met. Chem. Eng.* 13, 911-4(1915); cf. *C. A.* 9, 23, 1273.—With a proper arrangement of pipes or plates and wires acting as "collecting electrodes" and "discharge electrodes," resp., it is possible to produce a discharge from wires to the pipes or plates through the gases. These electrodes are insulated by high voltage insulators to insure passage of the current through the gas. Rapid polarity reversal keeps the particles in suspension, hence d. c. is necessary. The current is obtained by transforming a high voltage a. c. and converting into an intermittent high voltage d. c. The amount of power is relatively low and the smallest particles are collected. Fractional pptn. is possible. Several fields for research are suggested. W. H. B.

The construction of insulators out of "hard paper" or "pertinex." K. FISCHER. *Electrician* 76, 197-9(1915).—Pertinex consists of rolled layers of paper which have been impregnated with resin, heated and pressure applied. Its elec. properties are like those of paper; the other properties are like those of resin. Synthetic resins give best results. The mechanical strength is 120,000 kg. per sq. cm. Many shapes for indoor insulators are shown. The dielec. const. should have a mean value of 4.5. Pertinex insulator is designed to avoid a breakdown in the adjoining layer of air, or in the substance itself. W. H. BOYNTON.

Use of graphite in the lubrication of cylinders. F. W. CARTER. *Power* 43, 47-8 (1916).—C. describes tests showing that a decided saving is effected by the use of oil containing graphite over and against the use of straight oil. C. G. F.

Determining weight of deposit (WILSON) 7. An electrically conducting paint (JAMES) 26.

Electrolytic production of alkali metal cyanogen compounds. C. E. ACKER. U. S. 1,160,811, Nov. 16. A cast Fe or steel furnace, 1, with a refractory (Al_2O_3 or MgO) lining, 2, and heat-insulating brick casing, 3, has C anodes, 8, and Fe, Ni or C cathode, 13. BaCl_2 with a small amt. of NaCl is used in the chamber 14 in fused condition with an underlying layer of molten Pb, 16. The chamber 15 contains molten NaCN with or without admixture of Ba carbide, cyanide or other Ba salt from which the Ba may be subsequently displaced by Na. Metallic Na is liberated at the cathode but as soon as an appreciable proportion of Ba cyanide is present (this may be purposely introduced at the very start) the metallic Na displaces the Ba, which latter then immediately combines with C, free or combined, to form amorphous Ba carbide; and this substance remains suspended in the cyanide. N may then be introduced through pipe 20 and will pass down through the hollow shank of the cathode 13 to the lower surface thereof, and there spread out in the form of a thin layer between the face of the cathode, or "plunger," and the molten alloy, and thus come into effective reactive contact with the suspended Ba carbide with which it combines to produce Ba cyanide. The Ba in the Ba cyanide is then displaced by the metallic Na at the cathode, with the consequent production of Na cyanide and metallic Ba which latter again becomes available for the production of more carbide. If there is no free C present the Ba will seize upon one element of combined C in the Na cyanide to form Na cyanamide which is perfectly stable; but this latter substance is promptly reconverted into Na cyanide as soon as free C is added. C in the form of charcoal, from which the air and moisture have been removed by heat and vacuum, may be introduced through the hopper 22 into the reaction chamber. Fuel oil may be introduced through the oil feed device 21 under pressure, and will then come into contact with the red hot cyanide, which may also contain some cyanamide, below the surface of the plunger, at which temp. the oil will be broken up into finely divided C (lampblack) and H, the latter substance escaping through the overflow spout 11.

Drawn tungsten wire. GEN. ELÉC. CO. Brit., 13,076, May 27, 1914. The wire which readily takes a permanent set without heating is produced by heating in the presence of an oxidizing agent the wire, prepd. by one or more of the methods described in 21,513, 1906, 23,499, 1909 (C. A. 5, 2781), 8,031, 1910 (C. A. 5, 3543), and 9,877, 1912 (C. A. 7, 3472), and after the drawing operation has been completed. The wire may be treated after it has been mounted in a lamp, by passing current through it while the lamp is connected to the pump and before the usual degree of vacuum is reached, the small amt. of O present having the desired effect; or the wire may be treated before mounting it in lamps. The process may be applied to wire which has been treated for the prevention of off-setting. A modified process is described.

Rust-proofing. H. HANEMANN and F. HANAMAN. Ger., 284,803, Mar. 29, 1914. The article of Fe or steel is heated by means of an elec. current in an atm. of a gas, such as NH_3 , which forms a nitride. The metal can be heated to a white heat elec., and immersed in a nitride-forming liquid which yields a nitride-forming atm. by evapn. Or the articles to be treated may be immersed, as electrodes, in accordance with the Lagrange-Hoho process, in a liquid producing an elec. conducting and nitride forming

gas (such as NH_3). *E. g.*, the Fe article is connected, in a vessel, with a pole of a high tension d. c. The vessel contains an electrolyte composed of a conducting salt, preferably an NH_4 salt, and concd. NH_4OH . The other electrode, of large surface, is in combination with the other pole of the source of current. Upon completion of the circuit a mantle of gas is observed, and the Fe soon becomes incandescent. In consequence of electrolytic conduction and chem. action, the NH_4OH is volatilized with the formation of NH_3 and H_2O . By a thermic reaction between the NH_3 and the highly heated Fe surface, an exceptionally thick layer of Fe nitride is formed in a short time. After the incandescence, the article is allowed to cool in the electrolyte itself or in NH_3 gas which is contained in a bell over the electrolyte. The app. required is very simple.

Filament lamps. A. O. APPELBERG. Ger., 284,621, July 17, 1914. The filament consists of 2 or more V-shaped pieces.

Securing incandescent filaments. J. PLÉCHATI. Ger., 284,582, Feb. 18, 1913.

Arc lamp. SIEMENS-SCHUCKERT-WERKE, G. M. B. H. Ger., 285,250, July 24, 1913. The C electrodes are directed downward, and are regulated by longitudinal and lateral adjustments. A contact is actuated by the mechanism controlling the lateral adjustment which upon failure of the arc throws in a substitute resistance.

Incandescent vapor lamp. W. ROSENSTEIN. Ger., 284,437, Jan. 24, 1914.

6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

Sir Henry Roscoe. ANON. *Chem. Trade J.* 57, 583-4(1915); *Engineering* 100, 648(1915); *Chem. News* 112, 317-8(1915).—An obituary with a brief biography.

E. H.

Nature of residual valence. XII. Ammoniates of copper. F. EPHRAIM AND E. BOLLE. Bern. *Ber.* 48, 1770-7(1915); cf. *C. A.* 9, 2195.—The following compds. were studied by detg. the p - t curves over a short range: the "abs. temp. of dissociation" T , (*i. e.*, the temp. (abs.) at which the dissociation pressure reaches 1 atm.) was detd. by extrapolation, Q was calcd. from Nernst's formula. $\text{Cu}(\text{NO}_3)_2 \cdot 4\text{NH}_3$: t , 143° , p , 65 mm.; 153.5° , 85 mm.; 154.5° , 157 mm.; 175.5° , 255 mm.; T , 479° ; Q , 17.4 Cal. $\text{Cu}(\text{NO}_3)_2 \cdot 6\text{NH}_3$: -18° , 213 mm.; -12° , 264 mm.; -9° , 303 mm.; -3.5° , 390 mm.; 1° , 485 mm.; 6° , 600 mm.; 13° , 771 mm.; T , 284° , Q , 9.8 Cal.; some solid soln. is probably formed. $\text{Cu}(\text{ClO}_4)_2 \cdot 6\text{NH}_3$: 20° , 74 mm.; 28° , 119 mm.; 37° , 182 mm.; 47° , 247 mm.; 52° , 312 mm.; 60.5° , 409 mm.; 70° , 543 mm.; 75° , 617 mm.; 83° , 744 mm.; T , 284° ; Q , 9.8 Cal. $\text{CuS}_2\text{O}_6 \cdot 4\text{NH}_3$: 66° , 103 mm.; 77° , 108 mm.; begins to decomp. above 80° . $\text{CuS}_2\text{O}_6 \cdot 5\text{NH}_3$: -20° , 60 mm.; -13° , 113 mm.; -9° , 143 mm.; -4° , 183 mm.; 1° , 237 mm.; 9° , 351 mm.; 14° , 455 mm.; 19° , 585 mm.; 26° , 794 mm.; T , 298° ; Q , 10.4 Cal. $\text{CuS}_2\text{O}_6 \cdot 6\text{NH}_3$: 112° , 24 mm.; 149° , 34 mm.; 171° , 41 mm.; 184° , 77 mm.; T , 523.5° ; Q , 19.3 Cal. $\text{CuS}_4\text{O}_{14} \cdot 4\text{NH}_3$: 20.5° , 5 mm.; 50° , 87 mm.; 65° , 116 mm.; 82° , 240 mm.; 89° , 480 mm.; 93° , 753 mm.; T , 366° ; Q , 13.0 Cal. $\text{Cu}(\text{CNS})_2 \cdot 6\text{NH}_3$: -19° , 609 mm.; -15° , 680 mm.; -12° , 733 mm.; T , 258° ; Q , 8.9 Cal. $\text{Cu}(\text{CNS})_2 \cdot 4\text{NH}_3$: 17.5° , 3 mm.; 40.5° , 14 mm.; 55.5° , 39 mm.; 66.5° , 83 mm.; 72° , 123 mm.; 77° , 169 mm.; 84.5° , 249 mm.; 93° , 354 mm.; 104° , 574 mm.; 110° , 765 mm.; T , 383° ; Q , 13.7 Cal. $\text{Cu}(\text{CO}_3\text{H})_2 \cdot 4\text{NH}_3$: -13° , 9 mm.; -5° , 15 mm.; -2° , 19 mm.; 11° , 41 mm.; 20° , 66 mm.; 28° , 98 mm.; 36° , 184 mm.; 41° , 230 mm.; 47° , 269 mm.; 54° , 312 mm.; 62° , 367 mm.; T , 332° ; Q , 11.7 mm.; an inversion probably takes place at about 37° . $\text{CuC}_2\text{O}_4 \cdot 5\text{NH}_3$: -19° , 15 mm.; -2° , 15 mm.; 16° , 26 mm.; 16° , 48 mm.; 21° , 294 mm.; 27° , 438 mm.; 32° , 597 mm.; 38° , 788 mm.; T , 308.5° ; Q , 10.8 Cal.

GEORGE W. MORREY.

Absorption spectra of metallic-ammino complexes. I. Cobaltic amines and their chemical constitution. Y. SHIBATA. *J. Coll. Sci. Imp. Univ. Tokyo* 37, Art. 2, 1-28(1915); cf. *C. A.* 7, 1663; 8, 616.—The absorption spectra of 26 salts were examd. with a Hilger quartz spectrograph and iron arc as light source. The concns. were 0.01 *N*, 0.001 *N* and, in a few cases, 0.0001 *N*. Results are shown by curves, logs of layer thickness being plotted against wave lengths at limits of absorption. The curves all show minima (maximum absorption) near 2000 Å and 3000 Å; complexes containing two NO₂ groups in the 1-6 (trans) position show a 3rd band at about 4000 Å in 0.0001 *N* soln. The following conclusions are drawn: (1) The band at 2000 is little affected by substitutions within the complex and is probably due to a partially dissociated electron of the cobalt atom. The other bands are due to the metalloid atoms and are more or less displaced by substitutions. (2) Complexes of similar chem. constitution absorb alike and if the number of metalloid atoms in groups of similar character is the same, the complexity and molecular size have little effect. *E. g.*, the ammine and diethylenediamine complexes absorb alike but differently from the nitro or nitrito complexes. (3) The sign and valence of the complex ion does not affect absorption. (4) Optical isomers and the racemate absorb alike. (5) Stereoisomers in general absorb differently. (6) The anion is wholly without effect upon the absorption.

A. R. MIDDLETON.

Rare earths. Oxide and hydrates of neodymium. CH. GARNIER. *Arch. sci. phys. nat.* 40, 199-213(1915); cf. *C. A.* 9, 3162.—Very pure Nd(OH)₃, dried at 180° till the last trace of NH₃ was removed, was heated in a Heraeus furnace in a current of N. Two additional hydrates were found to exist: 2Nd₂O₃·3H₂O at 320°, clear brown with slight rose tint stable to nearly 525°; at this temp. Nd₂O₃·H₂O, paler brown, is formed and is stable to about 650°. The last in color and reflection spectrum is identical with the "Oxide A" described by Waegner (*Z. anorg. Chem.* 42, 118(1904)). Above 650° a slow transformation into the blue oxide takes place but this retains a gray tinge with a slight tint of brown; its spectrum shows some of the bands of the preceding hydrate. The clear blue oxide is obtained only by heating in a current of H and cooling in the same. A pastel of blue oxide heated in the oxy-hydrogen flame slakes in moist air to a rose powder, the reflection spectrum of which is entirely distinct from that of the blue oxide. The rose powder when heated to 1000° and cooled in H lost 12.7% wt. and its reflection spectrum then became identical with that of the blue oxide.

A. R. MIDDLETON.

Heteropoly acids which contain vanadium. V. Compounds which contain molybdic acid and selenic acid. W. PRANDTL AND W. VON BLOCHIN. *Z. anorg. Chem.* 93, 45-74(1915); cf. *C. A.* 9, 2744.—The following new compds. were prepd.: *Ammonium 2,5-selenitemolybdate*, 2(NH₄)₂O·2SeO₃·5MoO₃·3H₂O, from (NH₄)₆Mo₇O₂₄ and H₂SeO₃ or by weakly acidifying a strong NH₄OH soln. of MoO₃ and SeO₃, forms small rhombic prisms, easily sol. in H₂O. *Potassium and rubidium 2,5-selenitemolybdate* were similarly prepd. and are isomorphous with the above; the *barium* compd. was prepd. from a soln. on the NH₄ compd. and BaCl₂ soln. *Ammonium 2,8-selenitemolybdate*, 3(NH₄)₂O·2SeO₃·8MoO₃·5 and 8 H₂O, is best prepd. by acidifying with AcOH a soln. of 4 mol. MoO₃ and 1 mol. SeO₃ in NH₄OH; the corresponding K compd. could not be prepd. but the *barium compound* was obtained from BaCl₂ and the above NH₄ compd. Attempts to replace more than 2 mols. of MoO₃ in (NH₄)₆Mo₇O₂₄ with SeO₃ failed, indicating that 2 mols. of MoO₃ have a position in the mol. different from the others. When strong HNO₃ was added to an alkaline soln. containing MoO₃ and SeO₃, yellow ppts. of varying compn. were obtained, generally containing 2 SeO₃ to 12 MoO₃. When the soln. contained a large amt. of SeO₃ no ppt. was obtained, but the soln. yielded crystals of the compounds 2(NH₄)₂O·6SeO₃·6MoO₃·9H₂O and 2(NH₄)₂O·7SeO₃·6MoO₃·-

8H₂O. P. considers that the formulas assigned to complex heteropoly acids by Rosenheim are untenable, partly because they afford no explanation of the above fact that 2 of the MoO₃ groups in (NH₄)₂Mo₇O₂₄ have a unique position. G. W. M.

Ferroboron and manganoboron products. J. HOFFMANN. *Chem. Ind.* 38, 338-40 (1915).—A review of work on Goldschmidt's Feⁿ and Mn borides. It is concluded that the behavior of these borides with H₂O, H₂S, F, Cl, Br, I and N is of theoretical interest, but shows undesirable properties for the technologist. (Cf. C. A. 5, 639, 1732, 2226, 3017.) F. W. SMITHER.

Chromyl chloride. II. E. MOLES AND L. GOMEZ. Madrid. *Z. physik. Chem.* 90, 593-602 (1915); see C. A. 9, 3184. H. JERMAIN CREIGHTON.

Two series of derivatives of bivalent platinum. L. CHUGAEV AND V. LEBEDINSKII. *Compt. rend.* 161, 563-4 (1915).—The compd. Pt(MeCN)₂Cl₂ when carefully heated yields an isomeric form, which is termed the β form. Both the α and the β forms, when treated with liquid NH₃, take up 4 mols. NH₃, forming the compound Pt(Me₃CN)₂(NH₃)₄Cl₂, colorless, very sol. in H₂O, both Cl atoms are completely ionized. This new type of compd. is being further investigated. GEORGE W. MOREY.

The complex hydroxylamine compounds of bivalent platinum. L. CHUGAEV AND I. CHERNYAEV. *Compt. rend.* 161, 637-9 (1915).—The authors have prepd. a number of the compds. of the type [Pt(NH₂OH)_n(NH₃)_{4-n}]X₂. In aq. soln.

reacts readily with NH₂OH to form the complex $\left[\begin{array}{c} \text{NH}_3 \cdots \text{Pt} \cdots \text{NH}_2\text{OH} \\ | \\ \text{NH}_3 \cdots \text{Pt} \cdots \text{NH}_2\text{OH} \end{array} \right] \text{Cl}_2$ which

gives [Pt(NH₂OH)₂NH₃] on treatment with HCl at 100°. From this, the compound [Pt(NH₂OH)₂NH₃] may be readily obtained by heating it with 2 mols. of NH₂OH and liquid NH₃ in sealed tubes.

in aq. soln. with NH₂OH gives $\left[\begin{array}{c} \text{NH}_3 \cdots \text{Pt} \cdots \text{NH}_2\text{OH} \\ | \\ \text{NH}_2\text{OH} \cdots \text{Pt} \cdots \text{NH}_3 \end{array} \right] \text{Cl}_2$. All the representatives of the series [Pt(NH₂OH)_n

(NH₃)_{4-n}]Cl₂ are perfectly colorless and are more or less sol. in H₂O. The mol. cond. (t = 25°, V = 1000) gives values varying between 240 and 260, which corresponds to that of electrolytes of the type [Pt(A)₄]X₂. The chloride [Pt(NH₃)₂NH₂OH]Cl₂ gives the salt [Pt(NH₃)₃Cl] on the addition of HCl, the NH₂OH being eliminated and substituted by an atom of Cl. An analogous reaction occurs if the compd. [Pt(NH₃)₂(NH₂OH)Cl₂] is heated with HCl, the principle product being the acid [Pt(NH₃)Cl₂]H.

L. T. FAIRHALL.

Dithio-trimercuric salts. G. DENIGÈS. *Bull. soc. chim.* 17, 353-9 (1915).—**Dithio-trimercuric sulfate**, HgSO₄·2HgS, small, white, microscopic prisms, was prepd. by heating a dil. soln. of HgSO₄ with a little CS₂ on the steam bath; the *nitrate*, *chloride*, *bromide*, *acetate*, and *propionate* are similar and were prepd. in a similar manner. The same compds. were obtained when COS or HCNS was substituted for CS₂.

GEORGE W. MOREY.

Phosphorus-molybdenum compounds. III. **Complex hypophosphosomolybdenosemipentoxide molybdic acids.** F. MAWROW AND M. NIKOLOW. *Sophia. Z. anorg. allgem. Chem.* 93, 170-6 (1915).—M. previously (*Z. anorg. Chem.* 28, 162; 29,

136(1901)) described 2 compds. obtained by adding H_3PO_4 to a soln. of $(NH_4)_3MoO_4$ acidified with HCl; one has a violet color, the other blue. These compds. have been prepd. again and analyzed, and it is concluded that the violet substance is *hypophosphorosodimolybdenosemipentoxide-monomolybdic acid*, $Mo_6O_{13} \cdot 6H_3PO_4 \cdot 3H_2O$; the blue compd., *hypophosphorosomonolybdenosemipentoxide-trimolybdic acid*, $Mo_6O_{14} \cdot 6H_3PO_4 \cdot 4H_2O$. Addition of NH_4Cl , $NaCl$ or $CoCl_2$ to the soln. of the above blue compd. gave blue amorphous ppts. of *ammonium*, *sodium* and *cobalt hypophosphorosomonolybdenosemipentoxide-pentamolybdate*, $M_2O \cdot Mo_7O_{10} \cdot 2H_3PO_4$. 4, 4 and 7 H_2O , resp.

GEORGE W. MOREY.

Uranyl formate. ARNO MÜLLER. Magdeburg. *Z. anorg. allgem. Chem.* 93, 267-70(1915).— $UO_2(HCO_2)_2 \cdot H_2O$ was prepd. by pptg. a warm acid soln. of $UO_2(NO_3)_2$ with H_2O_2 , dissolving the pptd. peruronic acid in HCO_2H with the aid of a catalyzer (platinized asbestos), and evapg. the soln. so obtained in a vacuum desiccator. The crystals were freed from excess acid and H_2O with KOH and H_2SO_4 , resp., in a vacuum desiccator kept in the dark. $UO_2(HCO_2)_2 \cdot H_2O$ was obtained in hard octahedral, greenish yellow crystals; d_{18} , 3.695; insol. in EtOH, Et_2O , $CHCl_3$ and Me_2CO ; sol. in concd. $HCOOH$, $MeOH$, H_2O . The aq. soln. hydrolyzes with sepn. of a light yellow basic salt. Heated in a test tube, it decrepitates, and leaves a residue of U_2O_5 . It is sensitive to light. Its H_2O is lost completely at 110° , leaving a grayish green residue which is decompd. by H_2O and $MeOH$.

GEORGE W. MOREY.

Thermal decomposition of hydrogen peroxide in aqueous solution. Preliminary note. W. CLAYTON. Univ. Liverpool. *Trans. Faraday Soc.* 1916 (advance copy), 8 pp.—Merck's perhydrol was dild. to the required amt. The decomposing solns. were placed in various flasks (Jena glass, wax-lined flasks, and quartz) in electrically controlled thermostats at 50° and 60° . The rate of decompn. is shown to be extremely sensitive to colloidal org. matter. Volatility and presence or absence of stirring do not exercise appreciable influence. The purity of the water is shown to be the chief factor; the rate in tap water is fully 50 times that in water of cond. 1.1×10^{-8} ohm. It is doubtful if the surface of the vessel exerts an appreciable effect; effects previously attributed to the surface may have been due to variations in the content of org. matter.

A. R. MIDDLETON.

7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

Reagents for use in gas analysis. II. Chromous chloride. R. P. ANDERSON AND J. RIFFE. *J. Ind. Eng. Chem.* 8, 24-6(1916).—From their experiments A. and R. conclude that the prepn. of $CrCl_3$ by the method of von der Pfordten (*Ann.* 228, 112(1885)) and of Jannasch and Meyer (*Ann.* 223, 375(1886)) does not result in a stable soln., suitable for gas analysis; the prepn. of $CrCl_3$ by the reduction of violet $CrCl_4$ with H gives a soln. which, when properly filtered, is stable, but the absorption of O, though rapid, is not complete. It is improbable that $CrCl_3$ will ever be widely used in gas analysis, except in the presence of CO_2 and H_2S . E. W. BOUGHTON.

The absorption of oxygen in alkaline solutions. A new absorbent for oxygen. F. HENRICH. *Ber.* 48, 2006-9(1915).—By substituting KOH for NaOH in the alk. soln. of $Na_2S_2O_4$ used by Franzen (*Ber.* 39, 2069) for the absorption of O, H. finds that absorption occurs much more rapidly. A comparison of this soln. with one containing NaOH as the alk. agent was made by absorbing O from air in a Hempel pipet. The NaOH soln. required 9 min. to absorb the O from 50 cc. of air, whereas the KOH soln. required 3 min. only. The investigations of H. also show that solns. of pyrogallol in KOH absorb O more rapidly than those in NaOH. For special analyses, where the high

content of KOH in the absorption soln. is prohibitive, H. investigated the absorption capacity of solns. of 1,2,4-(HO)₃C₆H₃. 11.4 g. of 1,2,4-(AcO)₃C₆H₃ suspended in 20 cc. of H₂O were mixed with concd. KOH soln. (17.5 g. KOH). When soln. was complete, the mixt. was cooled and with 130 cc. H₂O was filled into a Hempel pipet. By this soln. the oxygen was completely removed from 100 cc. of air with vigorous shaking in 1/2 min. 100 cc. of oxygen were fully absorbed in 1/2 min. The soln. on standing for some months showed no trace of gas bubbles and the absorption capacity was unaltered.

L. T. FAIRHALL.

The action of metallic magnesium on the sulfides of tin, antimony and arsenic. C. PERTUSI. *Ann. chim. anal.* 20, 229-33(1915).—SnS₂ treated with powdered Mg in aq. suspension is reduced to Sn⁺⁺ and to Sn with the liberation of H₂S and the formation of Mg polysulfides. The sulfides of As in the presence of Mg and concd. HCl decompose readily with the evolution of H₂S and AsH₃, and are finally reduced to free As. The behavior of the sulfides of Sb is analogous to that of As. In systematic analyses divide the mixt. of the sulfides of the 3 elements into 3 parts. To the first add Mg powder until the yellow color turns brown; filter, treat the residue with HCl, heat the filtrate from this to boiling and identify Sn by adding HgCl₂. To the second portion add Mg and 4-5 cc. MeOH; warm gently and filter on a dry paper into a little concd. HCl. Sb remains in soln. but in the presence of As a yellow ppt. is obtained, easily recognized. Sb in the 3rd portion is identified by the method of Gas-taldi and Pertusi (cf. C. A. 9, 572).

H. L. OLIN.

A colorimetric method for the determination of copper and iron in pig lead, lead oxides, and lead carbonate. B. S. WHITTE. *J. Ind. Eng. Chem.* 7, 1035-6(1915).—*Pig Pb, PbO, and PbCO₃*: Weigh the finely divided sample (30 g. for refined products; 10 g. for crude) into a 400 cc. beaker and dissolve in hot HNO₃ (1:1) added portionwise (if basic nitrate forms, dil. with a little hot H₂O and boil). Add 32 cc. H₂SO₄ (1:1), let settle, filter, wash with small portions of warm H₂O, neutralize filtrate with NH₄OH, and add 4 cc. excess; boil, filter, wash ppt. well with hot H₂O and reserve for the detn. of Fe. Acidify filtrate with HCl (Fe- and Cu-free), adding not more than 2 drops excess; add 6 drops of K₃Fe(CN)₆ soln. (1:10) and filter through double papers, inspecting filtrate for Cu₃Fe(CN)₆. Dissolve the Cu₃Fe(CN)₆ ppt. from filter with alternate washings of NH₄OH and hot H₂O, keeping vol. within 40 cc.; acidify with HCl, transfer to a 100 cc. Nessler tube, dil. to mark with H₂O, and det. colorimetrically according to a modification of Carnelly's method (Sutton's "Volumetric Analysis," pp. 204-5), using a standard soln. of 0.393 g. CuSO₄·5H₂O per l. *Red lead*: Treat 30 g. with 40 cc. HNO₃ (1:1), slowly add 30-40 cc. of 3% H₂O₂, boil to effect soln., and proceed as above. *Na₂SO₄* may be used instead of the H₂O₂. *Fe in above compds.*: Dissolve the Fe(OH)₃ ppt. in HCl (1:1), make up to 300 cc. and mix, take 10 cc. and det. Fe colorimetrically with NH₄CNS as per Schaeffer (cf. C. A. 7, 1462). If the sample contains much Zn, acidify the filtrate from the Fe(OH)₃ with AcOH, add 5 cc. of 8% Na(NH₄)HPO₄ soln., boil, cool, filter, and det. Cu in filtrate. If a faint cloud of Pb₂Fe(CN)₆ develops, add a little Pb(NO₃)₂ soln. to the standard. *Indicator*: Litmus paper. Results are reported.

F. W. SMITHER.

Simple method of estimating antimony in stibnite. F. LEHMANN AND B. LOKAU. *Arch. Pharm.* 252, 408-12(1914).—Boil about 0.2 g. finely powered mineral 2 min. with 5 cc. officinal NaOH soln. and 10 cc. H₂O. Dilute with 10 cc. H₂O, filter into a 200 cc. glass-stoppered Erlenmeyer flask and wash the residue twice with 10 cc. hot H₂O. Boil the combined filtrate and washings 15 min. with 25 cc. officinal H₂O₂, add 25 cc. 25% HCl, cool and add 1-2 g. KI, dilute with 25 cc. H₂O, then titrate after a lapse of 5 min. with 0.1 N Na₂S₂O₄, being careful to shake the mixt. vigorously toward the end of the operation after each addition of thiosulfate.

W. O. E.

Determining weight of deposit. L. C. WILSON. *Metal Ind.* 13, 506-7(1915).—A continuation of a previous article (cf. *C. A.* 9, 756, 2492). This part deals particularly with the balance methods of detg. the wt. of Ag deposited and describes in detail the thiocyanate process for the detn. of Ag in the bath. The fire assay is also described.

W. E. RUDER.

Rapid volumetric procedures for determining combined alumina and basic alumina or free acid in aluminium salts. W. W. SCOTT. *J. Ind. Eng. Chem.* 7, 1059-61(1915).—"Rapid volumetric procedures are given for detg. combined and free Al_2O_3 in Al salts, followed by exptl. data showing reliability of the methods. Impurities such as commonly occur in these salts do not interfere, with exception of Fe, for which correction must be applied as stated. The methods are of special value for works control of liquors during the process of manuf. of Al salts, and the analysis of the finished product in daily routine analysis."

F. W. SMITHER.

Determination of sulfuric acid in the presence of phosphoric acid. T. v. FELLENERG. *Mitt. Lebensmit. Hyg.* 6, 191-5(1915).—An exptl. study reported in detail. The conclusion of Baragiola and Godet (cf. *C. A.* 9, 3321) that the presence of H_3PO_4 causes high results in the detn. of H_2SO_4 is confirmed. To reduce the error to a minimum in the detn. of H_2SO_4 in the ash of foods, etc., F. recommends adding the hot BaCl_2 soln. (in not too great excess) dropwise to the boiling slightly acid soln. (about 13-14 cc. *N* HCl per 100 cc.). Cf. Baragiola and Schuppli, *C. A.* 9, 1820

F. W. SMITHER.

A note upon the Kjeldahl method for nitrogen determination. P. L. BLUMENTHAL AND G. P. PLAISANCE. *J. Ind. Eng. Chem.* 7, 1044-5(1915).—A detailed report of a series of analyses under varying conditions by the methods in general use. The conditions followed were quite similar to those proposed by Pickel (cf. *C. A.* 9, 1286) except 50 cc. of concd. H_2SO_4 were used at the start. It is not satisfactory to rely upon a definite time of *total heating*, because of variations in gas pressure, and varying efficiency of burners. It is better to heat for a definite length *after clearing* (never less than 1 hr.).

F. W. SMITHER.

A rapid control method for the determination of sulfur in pyrites cinder. H. C. MOORE. *J. Ind. Eng. Chem.* 8, 26-8(1916).—Place 1.3738 g. of ground cinder in an Fe crucible containing 7 g. Na_2O_2 , and mix. Sprinkle a thin layer of peroxide over the surface and heat till completely melted, gradually increasing the flame. Cool, leach out the contents of the crucible with water, and add HCl to a slight excess. Transfer to a 500 cc. graduated flask, add 0.4-0.5 g. Al powder, shake and heat to boiling till nearly all Al is dissolved. Cool, dil. to mark, and filter. Dil. 200 cc. of filtrate to 450 cc., add 1 cc. concd. HCl, mix, and ppt. cold without stirring by adding slowly 25 cc. 5% BaCl_2 soln. from a buret. Mix and allow to stand 1 hr. Filter through a Gooch crucible and wash with cold water. Dry, ignite and weigh. $\frac{1}{4} \text{ wt. BaSO}_4 \times 100 = \% \text{ S}$. The method is rapid and accurate. If BaSO_4 is present it is decomposed by the fusion and the SO_4 pptd. later by BaCl_2 . The method would serve as a rapid approx. method for S in pyrites.

E. W. BOUGHTON.

Micro-reactions of carbon disulfide. G. DENIGÈS. *Bull. soc. chim.* 17, 359-60 (1915); cf. *C. A.* 10, 432.—The definite cryst. form of the dithiotrimercure salts and their extreme insolubility make them important in identifying their parent substance, CS_2 . Put the sample into soln. or suspension in a few cc. of water, add an equal vol. of (1) HgSO_4 soln. (HgO 5 g., H_2SO_4 20 cc., H_2O 100 cc.); or (2) a soln. of 0.30-0.40 g. HgCl_2 ; or (3) 2.5 cc. of an 80% soln. of $\text{Hg}(\text{NO}_3)_2$. Place the mixt. in a flask and immerse in a bath of boiling water for 15 min. in case the sulfate or nitrate is used, or 1 hr. with the chloride. Exam. the deposit under the microscope. The nitrate

forms hexagonal plates, the chloride cryst. groups resembling fish bones or fern leaves and the sulfate small prisms or lozenge-like plates. The presence of a few mg. of CS_2 may be detected by this method.

H. L. OLIN.

Methods for the determination of small amounts of sulfur dioxide in the atmosphere. A. E. WELLS, G. N. LIBBY AND R. J. MCKAY. Report Selby Smelter Commission. Bur. Mines, *Bull.* 98, 188-206(1915); cf. C. A. 10, 446.—The primary novel features of the methods (due to J. R. Marston) comprise: (1) Running a "blank" simultaneously and in the same manner as the "sample" detn., this blank being run on an equal vol. of air which, previous to a test, had been treated with an oxidizing agent to oxidize any reducing constituents that might be present. (2) Titrating the SO_2 in the sample with I in a starch soln. and obtaining the end point of the reaction by comparing the colors of the "sample" and "blank" solns., the I required to give to the "sample" soln. the same color as the "blank" being the equiv. of the SO_2 in the sample. A modification of Marston's method, sufficiently accurate for all practical purposes for detg. the SO_2 in air containing less than 3 or 4 parts SO_2 per million parts of air, is described in detail. With higher concns. there are errors, mechanically introduced, in this method. In order to eliminate these sources of error, the following method was devised, carefully tested out, and adopted: As *sample bottles* were used two 24-l. aspirator bottles of the same kind of glass, so that the action of heat and light on the I would be the same in each. The top tubulure of each aspirator is closed by a rubber stopper through which a glass stopcock is inserted. In the lower tubulure is placed a 1-hole rubber stopper, in which is fitted a glass plug extending for about 1.5 in. outside the stopper. As *test bottles* were used 2 bottles, each a 500 cc. wide-mouth specimen jar of uniformly clear white glass, and equipped with a 3-hole rubber stopper. Through one opening of the stopper is inserted a glass tube (about 4 mm. diam.), bent at right angles; through the second opening is inserted a tube (about 2 mm. bore), extending nearly to the bottom of the bottle and closed on the outside by a cap. In the third hole is inserted a glass tube. On the outside of the bottles, covering the lower half, except over a vertical strip 5 to 7 cm. wide, is pasted a uniformly white paper to serve as a background for color comparison. *Mixing bottle*: A 1-l. wide-mouth specimen jar is fitted with a 3-hole rubber stopper. In one hole a 4 mm. bore tube is inserted till it reaches to the bottom. In the other 2 holes are inserted glass rods as stoppers. *Buret*: The buret is equipped with a long small-bore delivery tube. *Vacuum pump*: A cylindrical hand pump, or a large wheel-operated pump (a standard combination beer pump with valves changed to produce vacuum) was used. The vacuum gage is a calibrated Hg column. *Solutions*: 0.002*N* I (1 cc. = 0.0224 cc. SO_2 at 0° and 760 mm.). *Starch*: 1 g. per l. (either sol. or grain) prepd. by adding the starch paste to boiling H_2O , boiling for several min., cooling slowly, and adding 2 g. of KI per l. *Preliminary procedure*: Bring about 500 cc. of the starch soln. to a desired light blue color with I in the mixing bottle; then transfer one-half of the starch-iodide soln. to each test bottle. To make the transfer so that the soln. will not come in contact with the air, the right angle tube of the test bottle is inserted in one of the holes of the stopper of the mixing bottle. The glass tube (third hole, see above) of the test bottle is opened, the mixing bottle inverted, and the soln. run into the test bottle through the right angle tube. Having transferred the soln. to the test bottles, the colors of the solns. in the test bottles are compared carefully to make sure that they are coincident, and that no dirt or film on the glass obscures the colors. The solns. are then transferred to the aspirators (sample bottles) by inverting the test bottles (with the right angle tube extending through the 1-hole stopper in the lower tubulure of the aspirator, removing the cap of second tube of test bottle, and opening glass stopcock). The soln. having been transferred, the lower tubulure of the aspirator is closed with a glass stopper, and the stopcock

closed. The aspirators are then shaken vigorously for about 5 min. to wash them and to oxidize any reducing gases. The solns. are then transferred back to the test bottles (as above), and the colors compared. If the 2 solns. have the same color, the aspirators are considered ready for use. If the colors are not the same, the starch solns. are again mixed, transferred to the test bottles and to the aspirators as before. The aspirators are again shaken, the whole operation being repeated until after removal from aspirators, the solns. are of the same color, or can be brought to the same color by the addition of not more than 0.1 cc. of 0.002 $N I$ to the lighter one. *Sampling:* Having washed the aspirators sufficiently so that their I consumption factors are zero, or a const. for both, a fresh starch iodide soln. is divided between the 2 aspirators as before, 250 cc. to each. One aspirator is then evacuated by pump to a 380 mm. vacuum; both aspirators are then carried to the point where the sample is to be taken, care being taken that both aspirators have the same exposure to sunlight. The sample is taken by opening the stopcock at the top of the evacuated aspirator, the vol. taken in being that required to bring the pressure in the aspirator back to atm. conditions. *Determination:* The 2 aspirators are shaken vigorously 60 to 80 times in such a manner that the sample and soln. are brought into intimate contact, the "blank" being shaken in the same manner as the detn. The starch solns. are then transferred to the test bottles in the manner above described. The colors of the solns. are then compared, and by means of the buret sufficient 0.002 $N I$ soln. is added through the hole of the glass tube in the "detn." bottle to bring the color to that of the "blank." In cases where the color of the detn. soln. is very much lighter than the blank, or is completely discharged, this soln. is titrated to a color slightly deeper than that of the blank, the 2 solns. are returned to their respective aspirators, shaken, and the colors compared as before. Following this procedure, provided the detns. are made not more than 30 min. apart, each detn. prepares the aspirators for the following detn. With a little experience and using a well prepd. starch soln. an analyst can detect, by comparison, a change produced by the addition of 0.1 cc. of 0.002 $N I$ to 250 cc. of the starch soln. It is more satisfactory to introduce the starch soln. into the aspirators before evacuating than to introduce it later after the sample is contained in the aspirator. With the starch soln. present in the aspirators when the sample is being taken the aspirator can be shaken immediately, to eliminate any possibility of the disappearance of SO_2 by oxidation or adsorption. There is no appreciable loss of I during evacuation. The starch soln. should be kept in tightly stoppered bottles protected from sunlight; soln. 1 day old is the most sensitive to color changes. When using this method for analyses of the air in the "smoke zone" of a smelter, the following notes should be recorded: time, temp. of air, barometric pressure, direction and approx. velocity of wind, capacity of aspirator used, initial vacuum in aspirator, cc. of 0.002 $N I$ soln. From the above is calcd.: vol. of sample at 0° and 760 mm., vol. of SO_2 equiv. to I , ratio of SO_2 to air, parts per million. A sample may be taken in less than 15 secs., and the detn. made in 5 min. Results are given in detail.

F. W. SMITHER.

Method for the determination of the total sulfur in the atmosphere present as dioxide or trioxide. A. E. WELLS. Report Selby Smelter Commission. Bur. Mines, *Bull.* 98, 206-10(1915); cf. C. A. 10, 446.—The absorption app. (see fig.) consisted of a train of 3 glass tubes, 4.5 cm. inside diam., and 110 cm. long, about $\frac{1}{8}$ of each tube being filled with glass beads. Over the top of each tube was fitted a glass cap, *k*, the joint being made tight by a thin rubber gasket. Through the top of each cap was inserted and sealed a 100 cc. sepg. funnel, *c*, and an outlet tube, *g*, 0.6 cm. inside diam., bent as shown. To the bottom of each tube was welded a glass stopcock, *f*, and an inlet tube, *h*, 0.6 cm. diam. The outlet tube, *g*, of one tube was connected to the inlet, *h*, of the next following by a glass tube, *d*, of the same diam., the joints, *i*, being

made tight, glass to glass, so that the rubber tubing was not exposed to the action of the gases or fumes from the inside. At a point 5 cm. from the bottom of each tube, the glass was so indented as to provide a seat for a glass wool pad (2 cm. thick), which held the beads in place. In order to maintain a steady flow of air through the absorption train entering at *a* and leaving at *b*, and at the same time to measure the vol. accurately, a steel tank of known capacity (116 l.) was evacuated to a known degree,

then connected to the absorption train and the air drawn through the train until the pressure in the tank was brought back to a known point. For evacuating the tank there was used a hand-wheel-driven double-cylinder pump superimposed on the tank itself. The pump and tank arrangement was a standard combination beer pump with valves changed to produce vacuum. The first tower of the absorption train contained Br or I soln.; the 2 following, either a dil. ammoniacal, or a 0.2% NaHCO_3 soln. App. (tubes, beads, etc.) were previously cleaned by treating with warm acid and washing with H_2O . *Procedure:* The solns. were introduced to fill the towers to above the top of the glass beads, the tank evacuated to the desired vacuum (e. g., 560 mm.), and then caused to draw the sample through the towers (about 1300 cc. per min.) until the vacuum was reduced to 180 mm. The tank was then evacuated again (requiring from 2 to 5 min.), and the aspiration repeated. At the beginning and end of each tank filling time, temp. of air in tank, vacuum in tank compared with outside atm. and barometric pressure of outside air (aneroid barometer) were noted. The total vol. of each sample averaged about 570 l. At the end of each sampling the solns. were drained through cock *f* into 500 cc. bottles. The first 2 tubes were washed with about 100 cc. of the stock soln., and the washings added

to the sample for analysis. The analyses were made by the usual gravimetric method (weighing as BaSO_4). Ammoniacal solns. were acidified with HCl , a slight excess of NaHCO_3 added, evapd. to about 80 cc., filtered, and washed. The soln. was acidified with HCl (litmus paper), 2 to 3 cc. of 10% BaCl_2 soln. added to the boiling soln., boiled 10 min., let stand 20 hrs., filtered, and weighed as BaSO_4 . In 177 tests, the first tube was found to contain over 71% of the total S. The S found in the solns. represented, within at least 5%, the total S in the air aspirated. With reasonable care in handling the solns., there is but small possibility of contamination with S from an outside source. Many detns. on "blanks" indicated that the analytical work was accurate to about 0.3 mg. of BaSO_4 . With a 570 l. sample 0.3 mg. $\text{BaSO}_4 = 0.05$ part SO_2 per million parts of air by vol.

F. W. SMITHER.

Apparatus for transferring gases in the Hesse method for the determination of atmospheric carbon dioxide. E. GROZA. *Bull. soc. Stiinta Bucuresti* 16, 156-9 (1914); *Chem. Zentr.* 1915, II, 297-8.—The vessel containing the air to be analyzed (provided above and below with cocks) is fastened on a stand and connects directly above to the neck of the Hesse flask mounted on same stand. The Hesse flask is filled with H_2O and is closed with a 2-hole rubber stopper; through 1 hole a glass tube passes to the bottom of the flask, with other end extending into the sampling vessel; a second glass tube extends through the other hole just below the stopper; to this tube is attached a rubber tube through which the H_2O in the flask can flow into a lower overflow vessel. The lower end of the sampling vessel is connected with a vessel filled with F to isolate F of rubber tubing evolved from the

outer air and at the same time to establish in the sampling vessel pressure equil. with the outside air. On opening the 2 cocks of the sampling vessel, the H_2O in the Hesse flask flows out and the air to be analyzed is drawn into the flask; the lower H_2O vessel is raised till the H_2O columns are of same height in each vessel (producing same pressure of the outer and inner air), the 2 cocks closed, the Hesse flask disconnected, and the CO_2 titrated in usual manner with $Ba(OH)_2$. App. is illustrated in the original.

F. W. SMITHER.

Methods for the determination of carbon dioxide and a new form of absorption tower adapted to the titrimetric method. E. TRUOG. *J. Ind. Eng. Chem.* 7, 1045-9 (1915).—Summary: (1) The grav. detn. of CO_2 by weighing of absorption app. gives accurate results with small amts. of CO_2 , slow aspiration, and due precautions in weighing and drying. (2) The detn. of CO_2 by absorption in alkali hydroxide and double titration has many disadvantages. The amt. of indicator used needs to be carefully regulated and standard end-points should be used. Under the best conditions, the end-points are not sharp. Good results can be obtained by observing the necessary precautions. (3) A new form of tower, described in the text, makes possible the use of $Ba(OH)_2$ as an absorbing medium for CO_2 under nearly all conditions. It also eliminates practically all contamination of CO_2 from the air, and greatly facilitates the washing. The titration has a very good end-point. The standard $Ba(OH)_2$ soln. is easily prepd. free of carbonates.

F. W. SMITHER.

A rapid method for the determination of carbon dioxide. W. H. WAGGAMAN. *J. Ind. Eng. Chem.* 8, 41 (1916).—The app. consists of flask for decompn. of carbonate, a condenser and an absorption train. By means of an Ostwald regulator the flame under the flask is regulated automatically. The flask is cooled by being surrounded by a coil of lead tubing, through which passes cold water. A cut of app. is given.

E. W. BOUGHTON.

The estimation of carbon dioxide in the ash of plant and animal substances. S. B. KUZIRIAN. *J. Ind. Eng. Chem.* 8, 89 (1916).—K. claims that the method of Gooch and K. (*C. A.* 5, 2475) using $5Na_2O \cdot 12WO_3$ is much simpler than the method of Boltz (*cf. C. A.* 10, 321) and gives excellent results.

E. W. BOUGHTON.

Determination of potassium hydrogen tartrate by the reduction of potassium iodate and iodide. KANTOR. *Mon. sci.* [5], 5, 273 (1915).—An application of Sander's picric acid method (*cf. C. A.* 8, 2132) based on the reaction $6RH + 5KI + KIO_3 = 6RK + 3I_2 + 3H_2O$. K. did not obtain concordant results by titrating the I directly in the reaction vessel, owing to poor end-point and slowness of reaction towards the end. However, by distg. in a Bunsen app., absorbing the I in KI soln., and titrating with $Na_2S_2O_3$ soln., excellent results were obtained. The method is applicable to pure $KHC_4H_4O_6$ or technical products. Results are reported.

F. W. SMITHER.

The hydrochloride method for the determination of alkaloids. G. D. BEAL AND ST. E. BRADY. *J. Ind. Eng. Chem.* 8, 48 (1916).—The method consists in extn. of the alkaloid with Et_2O , pptn. from this soln. as the hydrochloride by passing in dry HCl gas, evapg. and weighing the salt, then dissolving the hydrochloride in H_2O and titrating with standard alkali, using phenolphthalein as indicator. Results agree with those of U. S. P. method for conium seeds, tobacco and colchicum root.

E. W. B.

Determination of water in mineral greases. A. DEL CAMPO AND J. DE LA PUENTE. *Ann. Soc. espagnole de Phys. et de Chim.* June, 1914; *J. pharm. chim.* 12, 265 (1915).—Grignard's reagent $MeMgI$ in H_2O -free Et_2O is employed, and the vol. of CH_4 produced is detd.

S. WALDBOTT.

Apparatus for the culture of yeast used for the determination of various sugars by fermentation (TRAMBICKS) 1. Graphite (LANG) 18. Determination of the deposition of lead and arsenic on the soil in the Selby smelter zone (WELLS) 9.

8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY.

Pressure as a factor in the formation of rocks and minerals. JOHN JOHNSTON. *J. Geology* 23, 730-48(1915); see C. A. 10, 29. W. F. HUNT.

Decomposition of mineral sulfides and sulfo-salts by thionyl chloride. H. B. NORTH AND C. B. CONOVER. Rutgers Coll. *Am. J. Sci.* 40, 640-2(1915).—The authors' work on the application of this reaction to compds. produced in the lab. (C. A. 9, 3185) is here extended to include naturally occurring substances. The mineral tested was, in each case, powdered in an agate mortar, dried at 110°, and kept in a tightly stoppered bottle. The reactions for galena and cinnabar are similar: $\text{PbS} + 2\text{SOCl}_2 = \text{PbCl}_2 + \text{SO}_2 + \text{S}_2\text{Cl}_2$; pyrite gives FeCl_2 , thus: $6\text{FeS}_2 + 20\text{SOCl}_2 = 6\text{FeCl}_2 + 10\text{SO}_2 + 11\text{S}_2\text{Cl}_2$. Qual. expts. showed that pyrargyrite, covellite, boulangerite, enargite, marcasite, orpiment, realgar, stibnite, sphalerite, tetrahedrite, and arsenopyrite were decompd. quite readily by SOCl_2 , proustite with great difficulty, while molybdenite, cobaltite, and argentite were unaffected by the reagent after heating for several days. In the case of argentite this result appears remarkable since artificially prep'd. Ag_2S is readily decompd. by this treatment. L. W. RIGGS.

Mineralogy of Borneo. G. P. CHERNIK. *Trav. mus. acad. sci. Petrograd* 6, 49-95(1912); *Z. Kryst. Min.* 55, 184-91(1915).—I. *Platinum*. Analyses of 10 specimens of Pt according to the Deville-Stas method are given, the properties of each sample being stated. One strongly magnetic sample with sp. gr. = 14.15 contained 20.90% Fe, and is called "ferroplatinum." [Since $\text{Fe}:\text{Pt} > 1:1$ it should be named *platiniferous iron*.—ABSTR.] In another lot 28.87% Ir was found. Formulas are calcd. for 4 of the samples, and variety names given. II. *Minerals of the osmium-ruthenium group*. Of these, 15 samples are described, 5 of which were completely, the others only partially analyzed. In 9, $\text{Ir} > \text{Os}$, in 6 Os was in excess. Rh is always present, in one case to the amt. of 11.25%, and Ru is usually found, although perhaps present as inclusions of laurite in some specimens. Formulas are calcd. for the completely analyzed specimens, and variety names assigned; Vernadskii has recognized 6-8 varieties of "osmium-iridium," but C. thinks there are twice as many. III. *Gold*. Analyses of 12 samples are given, in one of which Pt amounts to 10.45% and in another Ir 30.36%. Formulas are derived for both of these. [The former is a new variety, which may be named *platiniferous gold*.—ABSTR.] A brittle Au-amalgam was also found, containing Au 34.23, Hg 60.57, Ag 4.78, Pt 0.12, insol. 0.09, sum 99.79%. IV. *Heavy minerals*. Analyses are given of rutile, topaz, ilmenite, chromite, ruby and zircon. E. T. W.

Some new mineral occurrences from the Tintic District, Utah. A. H. MEANS. Mass. Inst. Tech. *Am. J. Sci.* 41, 125-30(1916).—M. describes geocronite (?) ($5\text{PbS} \cdot \text{Sb}_2\text{S}_3$) from the 300 ft. level of the Colorado mine; adamite from the No. 3 shaft, Iron Blossom mine; daubréeite (?) ($2\text{Bi}_2\text{O}_3 \cdot \text{BiCl}_3 \cdot 3\text{H}_2\text{O}$), bismite (?) and jarosite from the 1200 ft. level of the Eagle and Blue Bell mine; and bismutite from the 1050 ft. level of the Victoria mine. The chem. and physical characters which led to the identification of these minerals are given. From the 600 ft. level of the Mammoth mine an apparently new mineral was found, occurring in large amts. and consisting of a heavy yellow friable material associated with limonite, barite, and a little erinite and mixite. About 0.5 kg. of this material was crushed to 80-mesh, vanned on a vanning shovel and about 30 g. of concentrate analysis by R. C. Wells gave the fol-

lowing results: Treatment of the concentrate with hot HCl gave a residue consisting of SO_3 16.60, BaO 31.90 (calcd.), and SiO_2 1.42 (by difference) showing 49.92% of the original concentrate to be barite. That portion of the concentrate sol. in hot HCl gave Bi_2O_3 28.17, As_2O_3 10.59, Fe_2O_3 3.88, Al_2O_3 0.44, CuO 0.12, CaO 0.62, MgO tr., SO_3 0.46, H_2O — 1.09, $\text{H}_2\text{O} +$ 1.43, P_2O_5 0.04, Sb_2O_3 1.26, PbO 1.12, sum, including insol. material, 99.14%. From the mineral association as observed in the district, anglesite, mixite, limonite and jarosite are assumed to be present. Deducting their mol. ratios from those furnished by the above analysis, and assuming that the remaining Fe_2O_3 , CaO , Sb_2O_3 , and Al_2O_3 are isomorphous with Bi_2O_3 , the formula $2\text{Bi}_2\text{O}_3 \cdot \text{As}_2\text{O}_3 \cdot 2\text{H}_2\text{O}$ is deduced. If 0.38% of H_2O , given off to anhydrous H_2SO_4 , be included as water of crystn., the formula is changed to $4\text{Bi}_2\text{O}_3 \cdot 3\text{As}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$. Both formulas appear to fit the data equally well. The mineral consists of cryptocrystalline aggregates, yellowish green with a tinge of brown, hardness approx. 3, sp. gr. 5.70, n about 1.60. The material described is homogeneous and of uniform chem. compn., and, unlike the other Bi arsenates, atelestite and rhagite, which are rare, it occurs in considerable amts. The name *arseno-bismite* is suggested as best conveying an idea of its chem. compn.

L. W. RIGGS.

The minerals of the St. Kreuz ore veins. R. KRAEMER. Strassburg. *Mitt. geol. Landesanst. Elsass-Lothringen* 8, 449-509(1914); *Neues Jahrb. Min. Geol.* 1915, I, Ref. 331-3.—Paragenetic tables, based on age relations of the crystals, are given, and the following minerals described, with analyses: siderite, ankerite, a variety of ankerite called "perlspar," Ag-bearing galena, and pitticite. The deposit is compared with those of other regions, and it is concluded that it is later than the pre-carboniferous granite.

E. T. W.

Mineralogy of the Kyshtym Mountains. I. Minerals of Datschen Kyshtym and Kassli. A. V. NIKOLAEV. Petrograd. *Trav. mus. geol. acad. sci. Petrograd* 6, 171-231(1912); *Z. Kryst. Min.* 55, 182-4(1915).—Descriptions are given of Au, Os-Ir, pyrite, quartz, amethyst, sapphire, magnetite (with analysis), Ti-bearing magnetite altering to hematite (analysis), chromite, oncosine, hydrobiotite, cerolite (analysis) and titanite, modes of occurrence and genetic relations being discussed.

E. T. W.

A regular intergrowth of rutile with calcite from Val Devero (Ossola). ANGELO BIANCHI. Univ. Pavia. *Rend. ist. Lombardo sci. lettere* [2], 48, 773-8(1915).—Regular intergrowth of rutile with calcite has not been reported. The specimen observed by B. showed a long slender rutile crystal traversing and supporting a limpid crystal of calcite; this was in a geode, among other variously interwoven crystals of calcite and rutile. The zone (111) of rutile was parallel to the zone (3140) of calcite, and accordingly the face (101) of the rutile and the face (1321) of the calcite were parallel.

E. J. W.

The artificial preparation and fusibility of iron calcium silicates. N. KONSTANTINOV AND B. SELIVANOV. *Ann. inst. polytechn. Pierre le Grand* 17, 427-45 (1912); *Z. Kryst. Min.* 55, 198(1915).—The system $\text{FeSiO}_3\text{-CaSiO}_3$ was investigated by thermal and optical methods. FeSiO_3 crystallizes well only when slowly cooled, and solidifies at 1145-1160°. Melts containing up to 65 mol. % CaSiO_3 solidify to material with fine cryst. structure, lower double refraction than pseudowollastonite, and $2V = 71^\circ$. With more CaSiO_3 pseudowollastonite separates from the system, its m. p. being 1510° , and complete crystn. being observed with 80% or more. The double refraction is high, and $2V = 4-5^\circ$. The curves showed no break at the ratio $\text{FeSiO}_3\text{:CaSiO}_3 = 1:1$, corresponding to the mineral hedenbergite, so this may be a secondary product, or a compd. of variable compn.

E. T. W.

Cancrinite from Ditró. B. MAURITZ. Budapest. *Math. term. Értesítő* 30, 673-87(1912); *Z. Kryst. Min.* 55, 206-8(1915).—Rose-red cancrinite occurring

associated with sodalite, nephelite and feldspar in a pegmatite vein was carefully selected and analyzed, yielding SiO_2 34.34, Al_2O_3 29.62, CaO 5.23, MnO 0.29, Na_2O 19.83, K_2O 0.35, CO_2 5.59, H_2O 5.16, sum 100.41%. This agrees very closely with the formula $\text{H}_4(\text{Na}_2, \text{K}_2, \text{Ca}, \text{Mn})_2\text{Al}_2\text{Si}_4\text{CO}_{11}$, with $\text{Na} + \text{K} : \text{Ca} + \text{Mn} =$ between 4:1 and 3:1. Previous work, which is reviewed, has yielded a different formula, but M. regards his material as purer than that heretofore analyzed, especially in respect to SiO_2 , which is set free in the course of the secondary formation of cancrinite from nephelite, and may not have been entirely removed. Thugutt's view that Fe is a characteristic constituent of cancrinites formed in this way is opposed. E. T. W.

Chemical disintegration of talc, chlorite, and biotite. F. MALT. *Dissertation*, Leipzig, 1913; *Neues Jahrb. Min. Geol.* 1915, II, Ref. 357-9.—The minerals studied were pale, greenish white talc from Greiner, Tyrol, pale green chlorite from Zlatoust, Urals, and biotite (anomite) from Miask, Urals. Their compns. are given. Talc loses most of its H_2O at red heat, with a break in the dehydration curve at $850-960^\circ$, leaving enstatite and SiO_2 . HCl , HNO_3 , or H_2SO_4 act very slightly on talc, while fusion with $\text{MgNH}_4\text{HPO}_4$ leaves 95.45% SiO_2 (tridymite?). Chlorite loses H_2O gradually up to 460° , then with break in curve up to 560° , above which the loss is gradual, the bulk having gone at red heat. Hydrated silica is left by digestion with dil. H_2SO_4 or concd. HCl . Biotite is bleached, and leaves scales of SiO_2 , optically negative and nearly uniaxial, by digestion with HCl , while HF expels the silica, leaving white scales of fluorides of Fe, Al, and Mg. W. B. JOHNSON.

The occurrence of ratovkite near Moscow. A. S. SERGEV. *Bull. acad. sci. Petrograd* 1912, 141-62; *Z. Kryst. Min.* 55, 170-1 (1915).—Ratovkite forms a layer 10-15 mm. thick between silicious marl and dolomitic limestone. It may be covered by a palygorskite-bearing substance, or lie directly upon silicious concretions. At times a second bed is also observable. The mineral is violet-blue, paler where mixed with CaCO_3 ; it has not yet been analyzed. E. T. W.

Mineralogy of (Russian) phosphorite deposits. J. V. SAMOILOV. *Verh. Komm. Moscow landw. Inst. Geol. Unters.* 4, 651-71 (1912); *Z. Kryst. Min.* 55, 192-3 (1915); continuation of C. A. 8, 889.—Fertilizing expts. showed that the phosphorite from the Gault rocks behaved differently from others; this proved to be due to the presence of H_2O -sol. P_2O_5 in the former. Two very complete analyses of phosphorites by Chervyakov are given, and the mineralogical compn. calcd. The results of microscopic and microchem. studies of various phosphorites are also described, and 2 generations of phosphate materials recognized, the H_2O -sol. compd. being in the 1st. A method of examg. phosphorites proposed by A. M. Nastjukov, consisting in comparison of the colors of ignited powders, proved valueless; the odor obtained on rubbing pieces together is of some practical use, yet not always dependable. E. T. W.

Chemical composition of the potash salt deposits in the Tertiary of upper Alsace. M. RÓZSA. Budapest. *Z. anorg. allgem. Chem.* 93, 137-50 (1915); cf. C. A. 9, 1449.—A discussion of the salt deposits in certain Alsace mines, from which it is concluded that the differentiation is largely to be ascribed to periodic temp. variations.

GEORGE W. MORREY.

The oil and gas fields of Ontario and Quebec. W. MALCOLM. Canada Dept. Mines, Geol. Survey, *Mem.* 81, 237 pp. (1915).—It was detd. that the oil and gas have accumulated in anticlines. Much of the oil is dark brown in color and has a sp. gr. of 31° to 35° Beaumé. It differs from the oils of the U. S. in that its S content is much higher, at times running as high as 2.5%; this makes it difficult to refine. Most of the wells produce less than 1 bbl. per day but use of economical pumping methods and also of a government buy at 10¢ per gallon. Some

bituminous shales are described containing 12.4% volatile and inflammable matter and leaving a black residue. A small deposit of "anthraxolite" containing 74% fixed C and 1.3% vol. matter was discovered. This is supposed to have formed from near-by beds of slate containing bituminous matter which has lost most of the volatile matter from the once plastic substance and retains the solid C. Various statistics, including the logs of the different wells, are given.

R. L. SIBLEY.

Devonian of southwestern Ontario. C. R. STAUFFER. Canada Dept. Mines, Geol. Survey, *Mem.* 34, 286 pp.(1915).—Chiefly a stratigraphical and paleontological study of the Devonian deposits of this region. A black shale is mentioned of which the carbonaceous matter is undoubtedly of vegetable origin, as it contains numerous plant fragments and large amts. of sporangia. Analysis showed 11.6% fixed C and 11.3% volatile combustible matter. A discussion of the economic products of the Devonian is included, and an extensive bibliography given.

R. L. SIBLEY.

Upper White River District, Yukon. D. D. CAIRNS. Canada Dept. Mines, Geol. Survey, *Mem.* 50, 143 pp.(1915).—Among the limestone deposits were noticed occasional reddish weathering beds which ranged in compn. from a siliceous limestone to a calcareous sandstone and which constituted a transition between the limestones and sandstones. In the vicinity of intrusive igneous rocks, the shales and argillites have become bleached and indurated and thus transformed into hard, cherty rocks with alternating white or grayish and dark gray to black bands. Some of the volcanic rocks are amygdaloidal and the cavities are largely filled with secondary minerals, mainly zeolites and calcite. It is in certain of these reddish amygdaloidal flows that native Cu has been found in this region. The color of the granitic intrusives depends on their constitution; the more acid varieties are almost white or light gray while the increasing basicity causes the color to become darker so that hornblendites are almost black. A statement of the mineral deposits of the locality is given. Cu ores are found associated with basaltic amygdaloids or in limestone at or near the contact with dioritic intrusives.

R. L. SIBLEY.

Arisaig-Antigonish District, Nova Scotia. M. Y. WILLIAMS. Canada Dept. Mines, Geol. Survey, *Mem.* 60, 153 pp.(1914).—A graywacke or impure quartzite and flinty slate are described. The slate is very siliceous. Such regional silicification is probably to be ascribed to the readjustment of the SiO_2 of quartz and the silicates which is favored by conditions of great pressure and high temp. This results in a slate in many cases harder than steel. The graywacke when studied microscopically showed quartz fragments, plagioclase and finer quartz, mica and other materials. A rhyolite corresponding in general characters to modern acid lava flows but differing from them in its complete felsitic texture is described as aporhyolite. Cu stains scattered about this region are explained by assuming that the CuSO_4 generally present in sea and river water was reduced to sulfide, during the deposition of sediments, by the action of decaying vegetable matter. Later these small sulfide deposits were converted to the carbonates by the weathering action of surface water. The economic features of various deposits are considered. An extensive bibliography is included.

R. L. SIBLEY.

Topical parameters of rocks. A. OSANN. *Sitzb. Heidelberg Akad. Wiss. Abh.* 26 (1914); *Neues Jahrb. Min. Geol.* 1915, I, Ref. 338-42.—If the values A , C , and F , obtained in the recalcn. of rock analyses according to O.'s well-known method, are plotted in the + octants of a triaxial, right-angled system of coördinates, and a plane is passed through the intercept-points, a "rock-surface" is obtained, which, together with the values s , n and m , represents the chem. compn. of the rock. The usual triangular diagram is really a gnomonic projection of this rock-surface on the plane xyz . The conditions obtaining in the isometric system are here applied, but if instead the orthorhombic system is followed, and different units used on the different axes, natural

differentiation phenomena can be brought out. The units to be used may be derived from the compn. of a fundamental magma of a petrographic province, the magma of a single differentiated mass of rock, the compn. of a sphere of rock to which that of a single layer is to be compared, etc. Further, if a picture of the chem. relations of igneous rocks is desired, the values derived from the av. analysis of the earth's crust may be used. The method of calcn. advized is illustrated by the latter example, the units on the 3 axes being detd. as 6.03, 3.95 and 14.26; for a given rock the values A , C and F are to be divided by these numbers, respectively, and the resulting parameters indicated by A_i , C_i and F_i , and called "topic." The value of this procedure is illustrated by 2 triangular diagrams; in the first the usual parameters are employed, and the points representing analyses of different rocks are crowded toward one side, while the mean compn. of the earth's crust is irregularly situated; and in the second topic parameters are used, whereupon the mean compn. of the earth falls in the center, and the analyses are grouped around it in a fairly uniform way. The translation undergone by the points on passing from one plan to the other is discussed, and the extreme value of the new plan in demonstrating differentiation relations between rocks pointed out. E. T. W.

The later stages of the evolution of the igneous rocks N. L. BOWEN. *J. Geology* 23 (Supplement), 1-91 (1915).—Stoping with abyssal assimilation and the formation of immiscible portions are unimportant factors in the production of the diversity of igneous rocks. Likewise the direct refusion of sedimentary terranes would often give rocks of mineral compn. never found in an igneous series. On the contrary, it is believed that the rocks of an area vary among themselves in a systematic manner which indicates derivation from a common stock through a systematic process of differentiation. This differentiation is controlled entirely by crystallization. The sinking of crystals and the squeezing out of the residual liquid are considered the important instruments of differentiation, and exptl. evidence is cited to show that typical igneous rock series would be formed from a basaltic magma if it cooled slowly enough.

W. F. HUNT.

Petrography of central Caucasus. Andesite-dacite from Keli Plateau and Liachva River. K. J. TIMOFEEV. *Kiev. Ann. Geol. Min. Russie* 14, 170-3 (1912); *Z. Kryst. Min.* 55, 203 (1915).—Analysis is given of a mineral occurring as phenocrysts in rock, from the Keli Plateau, and its compn. shown to be $3\text{MgSiO}_3 \cdot \text{FeSiO}_3$. It is thus an Fe-rich bronzite.

E. T. W.

An osannite-hornblende, a feldspar-free end-member of the alkali series from Old Pedroso. A. OSANN AND O. UMHAUER. *Sitzb. Heidelberg Akad. Wiss. Abh.* 16 (1914); *Neues Jahrb. Min. Geol.* 1915, I, Ref. 342-3.—Small veins of a black rock, consisting of amphibole with a little magnetite, occur in an alkali syenite at this locality in Portugal. The amphibole agrees optically with osannite, and analysis confirms its identity with that mineral. The parameters of the rock show clearly that it belongs to the alkali series. The rock melts to a glass even in the Bunsen-burner flame.

Mottled limestones and their bearing on the origin of dolomite. FRANCIS M. VAN TUYL. *Univ. Illinois. Science* 43, 24-5 (1916).—Limestones mottled with dolomite are regarded as "an incipient stage in the process of dolomitization, and it is believed that many dolomites have passed through such a stage in the progress of their formation.....there is convincing evidence that it took place in the majority of cases prior to or contemporaneously with the recrystn. of the limestone.....It seems probable, therefore, that the mottling was produced while the limestones were still beneath the sea, and that the sea water contributed the Mg."

Testing ores for the flotation process. O. C. RALSTON AND G. L. ALLEN. *Mining Sci. Press* 112, 8-13, 44-9 (1916), illus.—Detailed descriptions are given of the different machines in use and their operation: film-flotation and the Wood machine, the Potter or Delprat process, mechanical frothing by the Janney machine, the Hoover, the Slide, the Elmore, and the Callow machines. The most important points to be tested on a given ore with any given flotation machine are: method and fineness of grinding, kind and amt. of frothing agent, acidity or alkalinity, temp., necessity of preliminary agitation, effect of addition-agents in flocculating gang-slime. There may be a certain best combination of the above variables that will be entirely missed if a great many tests are not carried out; hence it is desirable to do the testing in a small lab. machine, where many trials can be made in a short time. Lab. manipulations are described.

F. W. SMITHER.

Thermal principles of the blast furnace. II. J. E. JOHNSON, JR. *Met. Chem. Eng.* 13, 905-10, 954-62 (1915); cf. *C. A.* 10, 36.—Directions are given in detail for calcg. the distribution of heat in the blast furnace in the 2 stages of ore treatment, (1) that of the prepn. of the ore for its descent into the hearth and (2) that of complete reduction and melting, on the basis of operating data furnished largely by Cornell (*C. A.* 9, 777) and Mathesius (*C. A.* 9, 1164). J. deduces from a consideration of the reactions involved that of a total heat consumption of 6400 B. t. u. per lb. of Fe produced, 5200 are expended in stage (1) in the partial reduction of the ore, the decompn. of CaCO_3 and H_2O and in raising the temp. of the materials to the critical point, i. e., the temp. of free running slag, and 1100 B. t. u. in stage (2) for the reduction of SiO_2 , the heating of slag and Fe above the critical temp., for making up radiation losses and for a 10% Fe oxide reduction which he thinks takes place in the bosh. The discrepancy of 100 B. t. u. is not excessive. The theorem that "for ideal working the C burned by the blast at the tuyères should be a max. and that dissolved by the O_2 of the charge a min. is explained by the fact that the dissociation of Fe_2O_3 is highly endothermic and the demand for C for heat production is much greater than for the reduction of the oxide. He sums up as follows: For max. economy the fuel must develop its max. heat and a certain portion of it must be developed above the critical temp. To accomplish this provide for max. oxidation at the tuyères, dry and heat the blast so far as possible, lower the critical temp. by governing slag viscosity, and then keep down hearth requirements by reducing slag vol. and protective cooling.

Ashio's copper-smelting works at Honzan, Japan. ANON. *Eng. Mining J.* 100, 998-1001(1915).—A detailed description with illustrations and drawings. The coarse first-grade ores are charged directly to the blast furnaces; the concentrates and fines are first briquetted or sintered in pots. Acid-lined, barrel-type converters are used. A new dust-settling system was recently installed. The ore deposits consist mainly of veins transversing Tertiary liparite (rhyolite) and, to some extent, the Paleozoic sediments of the district. The principal paleozoic rocks are slate, quartzite, and limestone. The chief vein constituents are chalcopyrite and pyrite, with frequently arsenopyrite, blende, galena, and pyrrhotite; occasionally bornite, chalcocite, cuprite, malachite, pisanite, azurite, and native Cu are all found in the oxidized zone. Rarely native Bi, bismuthinite, wolframite, fluorite, vivianite, ludlamite, and apatite are found. As gang, chlorite, quartz, and clay are common, with calcite occurring occasionally. The output from the concg. plants is about 300 tons daily (about 11% Cu). Cement Cu (about 2.3 tons per day, 66% Cu) is pptd. on scrap Fe from the mine water and drainings from the old dumps. The smelting plant treats annually about 100,000 tons. The converters produce about 65,000 lbs. of blister Cu per day, which is cast into 70 lb. bars or anode plates. Analysis of blister Cu: Cu 99.077, As 0.029, Bi 0.006, Fe 0.052, S 0.028, Se and Fe 0.038%, Au 0.0003 oz., Ag 0.1065 oz. F. W. SMITHER.

Report of the Selby Smelter Commission. J. A. HOLMES, E. C. FRANKLIN, R. A. GOULD, et al. *Bur. Mines, Bull.* 98, 528 pp.(1915).—A comprehensive publication giving in detail with tables, curves, analytical and other data, and numerous illustrations, the report of the commission organized for the detn. of questions of fact and other matters concerned with certain injunction proceedings at issue between the people of Solano Co., Calif., and the Selby Smelting and Lead Co. The report contains papers by the different investigators (cf. following abstracts and *C. A.* 10, 403, 404, 436, 437, 489, 504, on which the following conclusions are based. *Conclusions:* (1) With respect to the visible element of the smoke from the Selby smelter: (a) Prior to April 1, 1914, a nuisance was maintained in the smoke zone. (b) The installation of the bag house in connection with the sintering machines (Dwight and Lloyd type) has abated this nuisance. (c) Pb and As from the smoke of the smelter were deposited on the soil of the smoke zone during the period of time included between the beginning of operations and April, 1914, but the quantity of these metals so deposited was of no economic importance and did not poison the soil nor in any way produce a loss or reduction of crops. (d) The blackened appearance of many trees and plants in the smoke zone, which appearance is believed by many of the residents to be due to a deposit of Pb from the smelter smoke, is in fact due to the growth of a mold within the honeydew secreted by certain insects which infest the trees and plants. It contains no Pb whatever. (2) With respect to the SO₂ contained in the smelter smoke: (a) The Selby smelter has not maintained a nuisance with respect to producing within the smoke zone a disagreeable or objectionable odor, or with respect to affecting disagreeably or injuriously the throat and lungs of human beings or domestic animals living in the smoke zone. (b) The rare instances during the investigations when SO₂ from the smelter was present in the smoke zone in sufficient concns. to be observed by the residents by the

sense of smell do not constitute a nuisance; nor do these rare visitations prevent the residents of the smoke zone from the peaceful enjoyment of life and property. (c) The smelter has not maintained a nuisance with respect to economic damage to trees, vines, shrubs, or growing crops of any kind within the smoke zone. (d) The smelter has not maintained a nuisance with respect to the corrosion of wire screens or barbed wire in use within the smoke zone. (3) With respect to the future operation of the Selby smelter: (a) So long as the mechanical devices now used for clearing the smoke of the plant of its visible element are kept in operation the smelter will not maintain a nuisance with reference to injury to horses or other domestic animals, or with reference to injury to the soil of the smoke zone; nor will a nuisance be maintained by the smelter in these respects so long as the visible element is removed from the smoke by any means, mechanical or otherwise. (b) The app. now installed at the smelter which are used to eliminate the visible element of the smoke are subject to accident and are so constructed as to require occasional cleaning and repairing; and, for the purpose of cleaning and repairing the app. so used, the smelter will not maintain a nuisance in the smoke zone if it discharges visible smoke from the blast-furnace stack for a total period of no more than 48 hrs. in any one month of each calendar year; or if it discharges visible smoke from the roaster stack for a total period of 48 hrs. in any one month of each calendar year. (c) During the "closed season" (Mar. 15 to Nov. 15) the emission of smoke into the atm. from the Ropp roaster will be productive of a nuisance in the smoke zone unless the visible element is removed from the smoke before it is discharged into the atm. (d) So long as the total output of SO_2 discharged through all of the stacks of the smelter into the atm. is less than 80 tons per day of 24 hrs. during each hour of which day less than $3\frac{1}{4}$ tons of SO_2 are discharged the smelter will not maintain a nuisance with respect to a disagreeable or objectional odor or with respect to affecting disagreeably or injuriously the throat and lungs of human beings or domestic animals living within the smoke zone; or with reference to economic damage to vegetation or to the corrosion of wire screens or barbed wire in use within the smoke zone. An excellent bibliography on the effect of SO_2 on vegetation and animal life is appended. F. W. SMITHER.

Conditions in and around the Selby smelter and the Selby "smoke zone." A. E. WELLS. Report Selby Smelter Commission, Bur. Mines, *Bull.* 98, 63-81(1915).—A detailed description, with illustrations, tables and curves of the Selby smelter, its operations, and "smoke zone." The products of the smelter are refined Au, refined Ag, Pb bars, white lead, Pb shot, and bluestone. *Summary*: "On account of the geographical position of the Selby smelter and the 'smoke zone,' the topography of the surrounding and intervening country, and the general wind conditions existing during the greater part of the year, the Selby smelter is situated very unfortunately in so far as 'smoke troubles' are concerned. To a degree not usual around most smelters, all of the natural conditions tend to retard the dispersion and diffusion of the dust, fume, and gases that might emanate from the smelter, and make them more concd. over the 'smoke zone' than would be expected. We must expect, therefore, that the elimination of a comparatively small amt. of SO_2 gas, dust, and fume from the Selby smelter would be more serious during 8 months of the year than a larger amt. emanating from smelters situated in more favorable locations." F. W. SMITHER.

Investigations to determine the extent of the contamination of the atmosphere in the Selby "smoke zone" by the smelter emanations. A. E. WELLS. Report Selby Smelter Commission. Bur. Mines, *Bull.* 98, 82-212(1915).—A detailed account of conditions, methods, etc., with several pages of analytical data, illustrations, and a description of a portable lab., a set of app. arranged on an automobile body. Six or 7 min. after arriving at a place the total S app. could be started drawing in a sample, and the analyst could be taking an "instantaneous" sample for SO_2 detn. The results

obtained by this portable lab. were as accurate as those obtained at the fixed stations.

Summary. General conditions: (1) When the wind was from the west and blew the smoke from the smelter over the "smoke zone," there was present in the air of this area a higher concn. of SO_2 than was found when the wind was blowing from other directions. This concn. is higher than is normally present in the atm. outside of large cities. (2) The SO_2 contamination was due mainly to the emanations from the Selby smelter. Only when the wind was blowing the smoke directly from the smelter over the area were the higher concns. found. (3) The concn. of SO_2 in the air was not entirely proportional to the SO_2 output from the Selby smelter, for the concn. at any point was influenced to a great extent by the atm. conditions. (4) No indications were found of the presence of very high concns. during the early morning hours. The highest concns. were found in the samples taken about noon or in the early afternoon. (5) Under moderate or brisk wind conditions, the increase in SO_2 concn. was not very great in any part of the "zone," a max. of 1.25 parts of SO_2 per million parts of air being found when the smelter was sending out SO_2 at the rate of 70 tons per day. (6) Under a very slight west or southwest wind or a drift of air from the smelter across the "smoke zone" the concn. at certain places became relatively rather high for short periods of time. These high concns. were found only when there were puffs of smoke relatively undispersed or poorly dissipated drifting past the point of sampling. (7) These puffs of Selby smoke were not of long duration at any time and came only at infrequent intervals. They were present more often and with higher SO_2 content over the land lying nearest the straits and west of Dillon Point than in the city limits of Benicia or over the agricultural area bordering along the Vallejo-Benicia highway. At no time during the period of field investigations has the smoke from the Selby smelter been present in the city of Benicia to such an extent as to constitute a nuisance. This is fully established by extensive tests made. The tests to det. the sensibility of human beings to SO_2 showed that the av. person required to be surrounded by an atm. containing at least 3 parts of SO_2 per million parts of air before he could detect the presence of the gas either by smell or taste. The av. person did not consider concns. of 5 to 6 parts of SO_2 per million of air, lasting for several min., a nuisance. With concns. up to 20 parts of SO_2 per million, none of the subjects experimented upon experienced a feeling of nausea or any symptom other than an irritation of the throat and a tendency to cough. The data obtained in these tests check very closely the data obtained by Lehmann (*Arch. Hyg.* 18, 180-91(1893)). With an output from the Selby smelter of less than 100 tons SO_2 per day, and considering the fact that it is not during the wet season that the smoke is present to any extent over the area, and that during the dry season it is present only on infrequent occasions in sufficient strength to do damage, the smoke does not constitute a menace to the successful growing of crops in the smoke zone. From the fumigation expts. no indication of "invisible injury" to grain to decrease the yield of the crop was found. Detns. of the rate of deposition of Pb and As on the soil in the Selby smoke zone showed that when the roaster smoke was allowed to go out into the atm. unfiltered from the Selby plant there was undoubtedly a very slight deposition of Pb on the soil of the "smoke zone." However, the amt. so deposited was very small and would have required many years deposition to bring about an appreciable increase in the Pb content of the soil. With the successful operation of both the bag houses there is no possibility of further deposition.

F. W. SMITHER.

Determination of the deposition of lead and arsenic on the soil in the Selby smoke zone (Solano County, Cal.). A. E. WELLS AND C. E. BRANDT. Report Selby Smelter Commission. Bur. Mines, *Bull.* 98, 181-6(1915).—Pairs of glass plates (4×6 ft.) were set up at 3 points in the district; 1 plate of each set was covered with a thin coating of vaseline, the other left clean. The plates were slightly elevated from the ground and

set to face the direction of the smelter, at an angle of about 45° from the horizontal. The samples were removed from the plates by rubbing off the vaseline with clean cloths, the cloth being included with the sample in the subsequent analysis. The samples were treated with petroleum ether to dissolve the vaseline, and the residual solids weighed. The solids were then divided, one part being used for the detn. of As by treating directly in a Marsh app. and comparing with standard mirrors. The other part was treated with HNO_3 , then heated to fumes with H_2SO_4 , dild., and filtered. The PbSO_4 was dissolved in AcONH_4 , the Pb pptd. as PbS , dissolved in HNO_3 , then fumed with H_2SO_4 , dild., filtered, and weighed as PbSO_4 . Blanks made on the vaseline showed no Pb and a slight trace of As, amounting to a correction of less than 1 part in 1 million. Some of the samples were treated directly with HNO_3 and H_2SO_4 to destroy org. matter. The calcd. deposition per acre per yr. on the soil at the test stations showed from 13 to 113 g. of Pb and 0.2 to 1.2 g. of As. Determination of lead and arsenic present in the grasses and straw. *Ibid* 187-8.—A sample (254 g.) was digested with HNO_3 and H_2SO_4 until all org. matter was oxidized and then heated to SO_2 fumes, and Pb detd. as above. For As 5 g. were treated directly in a flask with H_2SO_4 and Zn, connected with the regular Marsh app. and the As mirror compared with standard mirrors. The amts. found, representing the max. deposit for a season, were: Pb 21 parts per million by wt., As 5 parts per million by wt.

F. W. SMITHER.

Determination of sulfur in plant foliage. G. C. BARTELLS, JR., AND C. E. BRANDT. Report Selby Smelter Commission. Bur. Mines, *Bull.* 98, 297-300(1915).—In connection with investigations of injury to growing barley by SO_2 , it was considered important to det. whether the plants subject to the action of SO_2 showed an increase in the amt. of S present in the foliage and grain kernels above that found in plants not subjected to the gas. The method used in the analyses is essentially the fusion method described in *Bull.* 107, Bur. of Chemistry. The tests showed that all the S was present (in fumigated vegetation and in checks) in fixed combinations. It is concluded that the detn. of the S content of vegetation is not sufficient alone to det. the extent of the damage that the vegetation may have endured by SO_2 , for great differences are found in the S content of normal uninjured vegetation.

F. W. SMITHER.

Disappearance of sulfur dioxide from dilute mixtures of sulfur dioxide with air. G. C. BARTELLS, JR. Report Selby Smelter Commission. Bur. Mines, *Bull.* 98, 308-23(1915).—Expts. reported in detail with illustrations and tabulated data lead B. to the following conclusions: (a) When a mixt. of SO_2 and air was introduced into a closed glass carboy and brought into contact with green vegetation, the SO_2 disappeared very rapidly and almost completely, due in great part to the simple absorption of the SO_2 by the live plant, to a small degree to the oxidation of SO_2 in an excess of moist air, and also to adsorption of the H_2O of the air with fixation of the SO_2 . (b) When a mixt. of SO_2 and air was left standing in a glass container for a considerable period in a dry atm. in diffused light, there was a disappearance of SO_2 (about 10% in about 30 hrs.), due partly to oxidation, partly to loss by diffusion, and partly to the adsorptive property of the glass in the presence of probable traces of H_2O (although mixt. was considered dry). (c) When SO_2 was mixed with air containing H_2O to the point of 50% satn., the rate of disappearance was much greater than in the dry air alone, due mostly to adsorption on the glass. (d) When SO_2 was mixed with air containing H_2O to the point of 100% satn., the rate of disappearance of the SO_2 was much greater and the disappearance more nearly complete than under any other conditions. (e) When a mixt. of SO_2 and air was exposed to the action of direct sunlight, a gradual disappearance of the SO_2 took place, the rate of its disappearance being greatest at those times when the temp. in the vessel was highest. This fact would preclude to a large extent the simple soln. of SO_2 by any H_2O present, for as the temp. of H_2O increases,

the solubility of SO_2 decreases to a marked degree. A part of the SO_2 was adsorbed, varying with the amt. of H_2O present. (f) In all of these tests both oxidation and absorption took place. In a moist atm. both of these took place to a greater degree than in a dry atm.

F. W. SMITHER.

Investigations of the gases from the Dwight & Lloyd sintering machines at the Selby smelter. A. E. WELLS. Report Selby Smelter Commission. Bur. Mines, *Bull.* 98, 324-37(1915).—The only emanation from the Selby smelter (Solano Co., Cal.) that now contaminates the atm. is the SO_2 from the sintering machines. Investigations, discussed in some detail, were made for the purpose of detg. the possibility of reducing the amt. of this SO_2 output. *Summary:* Under the charge and operating conditions consistent with good roasting and sintering results, at least 75% of the total SO_2 from the machines was obtained in a gas vol. that had an av. concn. of 7.3% SO_2 . The roasting area of a machine has been divided into 4 sections, beginning at the ignition part. Section 1 has a length of 3 ft.; section 2, 7 ft.; section 3, 5 ft.; section 4, 5 ft. From section 2 alone has been drawn out a vol. of gas containing 5.5%, or 55% of the total SO_2 produced in the machine, from section 3 a gas containing 2.8% SO_2 . By conducting the gas from section 3 into a hood placed over section 2, the concn. of the gases in the exit pipe from section 2 was raised to an av. content of 7.3% SO_2 . This gas then contained 78% of the total SO_2 eliminated by the machine. In order to gain these results, certain conditions must be maintained, the most essential of which are: (1) The variations in the physical condition of the charges should be kept within limits that will exclude very coarse Pb concentrates, coarse raw mat, lumpy materials, and the presence of an excessive proportion of Pb slimes. (2) The constituents of the charges should be intimately mixed. (3) The charges should contain the correct H_2O content, which should also be intimately mixed with the other materials. (4) The ignition of the charges should be carefully watched. All of these conditions are equally as essential for the best roasting and sintering results as for the production of a gas of high concn., and the attainment of these conditions is well within the range of smelter operating practices. The chem. compn. of the charges may vary within the wide limits that will still allow of a successful roast and sinter, and, if the conditions mentioned above exist, the high gas concn. can be realized. Should it be desirable, 85% of the total SO_2 can be concd. in a vol. that will contain a concn. of at least 8% of SO_2 . This would call for a rather more complicated arrangement of fans and air-pipe lines, but would still be practical. With a concn. of 7 to 8% it is possible to apply a com. scheme for the recovery of SO_2 , either as liquid SO_2 , H_2SO_4 , or S.

F. W. SMITHER.

Conditions of plant life in the Selby smoke zone, Jan. 1 to July 1, 1914. J. W. BLANKINSHIP. Report Selby Smelter Commission. Bur. Mines, *Bull.* 98, 381-97 (1915); illustrations.—“ SO_2 to do material damage in dry weather to vegetation within 0.5 hr. must be so strong as to be almost unbearable, or if dil. must be very frequently repeated or almost const. over the area injured in order to affect vegetation at all.”

F. W. SMITHER.

The occurrence of sulfur dioxide injury to plants in the Selby smoke zone. W. W. JONES. Report Selby Smelter Commission. Bur. Mines, *Bull.* 98, 398-427 (1915); illustrations.—A report on SO_2 injury, the common fungous diseases, the presence of insect pests, the nature of the soil, the cultural methods and practices, etc.

F. W. SMITHER.

Agronomic and soil conditions in the Selby smoke zone. C. F. SHAW AND E. E. FREE. Report Selby Smelter Commission. Bur. Mines, *Bull.* 98, 451-67(1915).—The soils of the region (Solano Co., Cal.) are loams or silts derived from the weathering of sandstones and shales which are extensively exposed. There is little or no

river silt or other soil material transported from a distance. The topography is between rolling and mountainous. The conclusions in the matter of soil pollution are as follows: (1) Arsenic is certainly a normal, though extremely minute, constituent of the soils of the region, and Pb is probably so. (2) The past contamination of the soils by Pb and As from the smelter is possible but unproven and appears not to be susceptible of proof. (3) The quantities of Pb and As added, if any, have been small and of the same order as the quantities of these elements normally present in the soils. The max. amts. of Pb and As found are far too small to have any injurious effect on plants grown in the soils. Analytical results are reported. A letter from C. B. Lipman confirming the above opinion is given.

F. W. SMITHER.

Investigation of live-stock conditions and losses in the Selby smoke zone (Solano County, Cal.). C. M. HARING, K. F. MEYER, *et al.* Report Selby Smelter Commission. *Bur. Mines, Bull.* 98, 474-502 (1915); illustrations.—*Conclusions:* It appears probable that in the past considerable damage to horses has occurred in the smoke zone from Pb emanating from the Selby smelter. To date (July 19, 1914) no evidence has been found of injury since March, 1914. There is no evidence or suspicion that the smelter smoke has ever injured cattle or hogs. It has been claimed that sheep have been injured, but no clinical evidence could be procured to substantiate such assertions. Until additional evidence can be found, there is no reason to believe that the Selby smelter smoke is now doing any damage to live stock.

Hardening steel rails. C. P. SANDBERG. *Brit.*, 18,972, Aug. 22, 1914. The head only of a rail, which retains the heat existing therein after the completion of the rolling operation, is cooled to a point below the critical temp. by directing thereon from a pipe a jet of fluid, such as air or steam, or H_2O , the rail being subsequently allowed to cool naturally. A rail made of steel containing 0.5% of C, 0.9% of Mn and 0.08% of Si is referred to.

Coating iron and steel. *Brit.*, 18,932, Aug. 21, 1914. W. E. WATKINS. A coating of Cu, or other metal having less affinity for O than has Fe, is formed on Fe and steel sheets, etc., by deposition from an oxide compd. The compd. is applied to the surface in admixt. with a neutral vehicle, such as oil, and the coated sheet is passed through a furnace chamber heated to the welding temp. of Fe. The coating itself becomes covered with a protective layer consisting substantially of Fe_2O_3 , which may be removed after cooling.

Coating surfaces with metals. H. SCHLÖTTER. *Brit.*, 18,970, Aug. 22, 1914. The coating metal is vaporized in a chamber having a throttled outlet, so that the issuing jet impinges against the surface with sufficient violence to secure adhesion.

Treating zinciferous ores with sulfurous acid. ERZ-VERWERTUNGS-GES. M. B. H. *Ger.*, 284,982, Apr. 25, 1913. In view of the observation that $ZnSO_3$ dissolves much more readily than the oxide, ores or other materials containing ZnO are treated first with combined SO_2 , whereby the ZnO is converted into $ZnSO_3$, which is then treated with gaseous SO_2 and converted thereby into $ZnH_2(SO_3)_2$. The conversion into the monosulfite can be effected readily by adding to the roast a bisulfite soln., as follows: $ZnO + ZnH_2(SO_3)_2 = 2ZnSO_3 + H_2O$. This treatment of the ore can be

carried out in special app. outside of the gas-absorption app. The resulting monosulfite is then stirred up with H_2O and treated with SO_2 gas. This SO_2 gas is quickly and completely absorbed with the instant formation of bisulfite. The conversion can be effected well and completely in the tower despite the short period of passage. *E. g.*, if a 5% Zn soln. be made from 16 tons ore with 25% Zn content, the 4000 kg. Zn would require 80 tons H_2O and 8000 kg. SO_2 . At first, 80 tons H_2O are mixed with 1 ton ore, and treated with SO_2 gas until the 250 kg. of Zn in the ore mixt. are completely dissolved. The resulting 0.3% Zn soln. is allowed now to run off from the extd. material, and is then brought to act with 1 ton of fresh roast. The soln. and the material are first intimately mixed, whereby the ZnO of the ore is converted by the bisulfite of the soln. into monosulfite. SO_2 gas is then introduced until all monosulfite is dissolved. After removal of the extd. material the soln. is mixed with 2 tons of fresh roast. The soln. obtained by repeated introduction of SO_2 gas is mixed with 4 tons of roast, and the soln. finally obtained from this is mixed with 8 tons of roast. In this manner the SO_2 gas comes only in contact with monosulfite. Only on a very small portion of the ore does the gas act directly. This even can be prevented by reserving a small portion of the concd. soln. and bringing it into contact with the first ton of ore. The process may be made continuous by conducting the SO_2 gas through a reaction tower, and introducing a mixt. of the previously formed monosulfite, with H_2O , counter to the gas. The monosulfite is produced continuously, the lye drawn from the tower for admixt. with the fresh roast being returned after the extd. material has been withdrawn from below.

Recovering values from the residues obtained by dressing gold and silver ores by the oil flotation process. S. MICHAELIS. *Ger.*, 285,229, Apr. 18, 1913. The oil adheres only to the metallic particles or compds. of the ore and carries them upon the surface of the liquid, while the incompletely disintegrated, and, therefore, but partially oil-covered portions do not rise to the surface, but are suspended over the dead gang and are removed therewith without being exhausted of their values. This objection is overcome, and a yield of 80-90% is obtained (as against the heretofore obtained yield of 30-40%) by taking advantage of the lower sp. gr. of the intermediate product, due to its oily character, and sepg. it by centrifugation from the dead gang. The ore is first stamped, and mixed dry with oil, in a suitable app. The resulting oily ore slurry is conducted into an acidified liquid wherein the completely comminuted metallic constituents sep. first by rising to the surface. After these are removed, the dead gang, with the layer of oily, imperfectly disintegrated ore above it, is drawn from the container and centrifuged.

Briquetting flue dust containing iron. R. HÜBNER. *Ger.*, 285,464, July 19, 1912. In order to render the briquets so firm that they will bear the charge in the blast furnace and at the same time retain their form until all the contained Fe is reduced, the flue dust is stirred up with coal, kaolin, quartz, lime, magnesia, HF and H_2O , to a stiff plastic mass which is briquetted in the usual manner. *E. g.*, a mixt. is prepd., consisting of ferruginous flue dust 54, coal 16, kaolin 7.5, quartz 8.4, CaO 10, MgO 3.5 and HF 0.6 parts. The constituents are mixed first without the HF, then to the HF is added sufficient H_2O to form a stiff plastic mass, and the briquets are made from this product. The amt. of HF is in inverse proportion to the amt. of Fe in the flue dust, and falls to between 0.6 and 5%. The HF is said to induce the formation of a basic, readily fusible slag in the blast furnace.

Briquetting soot with flue dust or fine ore. F. SCHUSTER and C. LICHTENSTERN. *Ger.*, 285,078, Dec. 5, 1913. Heretofore the use of soot has been impractical because of the action of the blast in blowing it away. This difficulty has been overcome by mixing the soot first with a liquid binder. The soot, preferably moistened first with H_2O , is mixed with the liquid binder, as salt solns. or salt mixt. solns. and acids, before

it is mixed with the ore dust material, whereby it is rendered so consistent that it can be mixed with the fine dust or ore dust in mixing app. Briquetting is effected by compressing the material and allowing it to harden. The resulting briquets require but a small amt. of fuel, in the blast furnace, for the reduction.

Decarbonizing iron, steel, chromium, manganese, nickel, cobalt and other metals containing carbon. NITROGEN PRODUCTS CO. Ger., 285,465, Mar. 7, 1913. The metal, solid or fused, is brought into contact simultaneously with N and an alkali or alk.-earth metal, such as Ba. The C is removed by distg. off the resulting cyanide from the metal. A suitable app. is specified.

Case-hardening iron. K. STRATMANN. Ger., 284,859, Mar. 21, 1914. The tools are packed, together with pulverulent hardening agent, in vertical retorts adapted to be discharged from below, in containers of combustible or carbonized material, such as paper, wood, and the like, which fall to pieces upon incandescence.

Hardening and tempering steel pegs, tuning pins, etc. J. W. DUNKER. Ger., 285,503, July 14, 1914. An app. is employed in which the articles are conducted intermittently, in progressive order, through the heating canal.

Casting wheels from two kinds of steel. H. R. KEITHLEY. Ger., 283,287, Sept. 16, 1913. The casting is effected in such manner that after pouring and compressing into the mold, the hard metal forms the rim and flange.

Coating metal with aluminium. ALLGEMEINE ELEKTIZITÄTS-GE. Ger., 285,245, Sept. 28, 1912. Al powder is mixed intimately with NH_4Cl and Zn powder. The articles to be treated are introduced into a furnace and covered with the mixt. The furnace is then closed and revolved slowly. The articles are maintained for about 7 hrs. at a temp. of about 450° , whereupon they are removed and heated for 15 to 20 min. at $700-800^\circ$. Good results were obtained with a mixt. of 70% Al, 23% NH_4Cl and 7% Zn. The Zn may be substituted by graphite, in which case Al 60%, graphite 30% and NH_4Cl 10% are employed. By employing this mixt. the temp. can be raised to 700° . The product has the appearance of Al bronze and takes a high polish. It is covered with a layer, 0.2-0.5 mm. thick according to the period of the treatment, of an alloy which is exceptionally hard and tough and which is so firmly united that it cannot be removed from the base metal. It is not attacked by acids. In an atm. which prevents oxidation, heating of the article with pure Al powder will suffice in many cases.

Electric resistance welding of aluminium. ALLGEMEINE DEUTSCHE ALUMINIUM-KOCHGESCHNEIDFABRIK G. G. GER. Ger., 285,490, Dec. 8, 1912. Due to oxidation in the elec. welding of Al the electrodes are quickly rendered impure, lose their smooth surface, and permit access of air to the point of welding. To obviate this difficulty a movable piece of metal or other material of sufficient cond. is interposed between the point of welding and the electrode. It may be removed and replaced as often as necessary, and must be less fusible than Al.

10. ORGANIC CHEMISTRY.

CHAS. A. BOUILLER.

Formation and preparation of glucosemoneacetone. JAMES C. IRVINE AND JAMES I. A. MACDONALD. Univ. St. Andrews. *J. Chem. Soc.* 107, 1701-101515. d. M., C. A. 8, 907.—It is shown that, contrary to the opinion of Fischer (*Ber.* 28, 2496 (1895)), glucosemoneacetone (A) is not an intermediate product in the formation of glucoediacetone (B), but is formed from this as a result of the great instability of 1 of the Me_2C -groups in the mol. While 0.1% HCl hydrolyzes both groups at 50° ,

only 1 group is removed at 30°, this being the non-glucosidic group. Although 2 glucosidic forms of (A) are possible, only the variety described by Fischer was isolated. 65 g. finely powdered glucose were shaken 8.5 hrs. with 1200 cc. MeOH containing 1.5% HCl and let stand for 60 hrs. After shaking 2 hrs. with BaCO₃, filtering, and evapg. *in vacuo*, 700 cc. acetone containing 0.5% HCl were added and shaken at 35° for 20 hrs. Acid was removed with Ag₂CO₃ and the acetone distd. off on the H₂O bath. Several extns. of the residue (50 g.) with petr. ether removed (B), leaving a residue sometimes consisting of (A) and sometimes of a solid soln. of (A) and (B). The (B) obtained was recrystd. from petr. ether and half-hydrolyzed as follows: 40 g. were dissolved in 850 cc. H₂O containing 0.1% HCl and kept in a thermostat at 30°. [α]_D decreased gradually, and usually reached a const. value in ca. 3.5 hrs. After neutralization with Ag₂CO₃ and treatment with blood charcoal, the soln. was evapd. to 200 cc., filtered from sepd. Ag, and concd. to a syrup *in vacuo*. The residue, extd. with boiling, neutral EtOAc, gave 28 g. (88% of the theory) of (A) on cooling. It seps. (best from not too concd. solns.) in bulky, gelatinous form, and is best freed from adhering solvent by drying at 40° in a current of dry air. A further recrystn. from H₂O is necessary. C and H detns. were unreliable for some reason, and the best criterion of purity was found to be hydrolysis at 75° with 0.1% HCl, when [α]_D should become about 52.5°. The EtOAc mother-liquors, when concd., deposited warty aggregates which m. constantly at 150–1° when crystd. from EtOAc, but were ultimately fractionated from H₂O into (A), (B), and glucose, indicating that the crystals were a solid soln. of (A) and (B), which suffered slight hydrolysis during the fractionation. However, the polarimetric results obtained on hydrolysis of the crystals indicated the presence of a strongly *d*-rotatory substance, possibly an isopropylidenediglucose. Methylation of the mixed crystals according to I. and Scott (C. A. 7, 2383) gave results which were of value only in confirming the presence of (B) and showing that some compd. was originally present which contained fewer than 3 OH groups. Trimethyl-glucosemonoacetone was prepd. from (A) according to I. and S. On hydrolysis, isolation of the product in the usual manner, and distn. in high vacuum, there was obtained, instead of the expected sugar, which was to be used in the synthesis of glucosamine, trimethylglucosone, syrup, b_p 153°, reacts energetically with Fehling soln. in the cold, [α]_D –15.7° in H₂O. The rotation in H₂O is unaffected by the addition of H₃BO₃, indicating that the Me groups are in the γ, ϵ, ζ -positions.

M. HEIDELBERGER.

Nature of the vibrations causing the color of dyes. EDWIN R. WATSON AND DAVID B. MERR. Dacca, India. *J. Chem. Soc.* 107, 1567–78(1915).—It was previously pointed out (C. A. 8, 2368 *et seq.*) that those dyes which are quinonoid in all possible forms show deep color, provided different PhH nuclei become alternately quinonoid. It is now proposed that the process taking place during these changes in a long series of conjugated double and single bonds may be visualized by the analogy of the pulsation running along a freight train when the engine is started or stopped. The breadth, indefiniteness, and frequent asymmetry of the absorption bands of dyes suggest forced vibration. If the analogy holds good, in very similar mols. the period of the principal vibration causing color would be proportional to the length of the conjugate chain. Measurements showed this actually to be the case. The following pairs of substances were investigated: Michler's hydrol and ketone, the corresponding unmethylated derivs., quercetin reduction product and quercetin, morin reduction product and morin, apigenin reduction product and apigenin, pyronine-G and 3,6-tetramethyldiaminoxanthone, 3-hydroxyfluorone and 3,6-dihydroxyxanthone. The arrangement of the chains of double bonds in these compds. is shown in a series of diagrams. In the first 2 pairs, the ratio of the wave lengths of the max. of the principal

bands should be 5:3, while for the flavone dyes an arrangement of the bonds is assumed which also gives the ratio 5:3. It is shown that the ratio 4:3 is possible for the xanthone and fluorone dyes. These ratios were experimentally verified in every case, the figures being given. A criticism is also made of the theories attempting to refer the absorption of a dye to that of its "mother substance." The applicability of Baly's new theory (permitting the calcn. of absorption bands in the visible and ultra-violet from the infra-red absorption (*C. A.* 9, 1001, 3163)) to the anthraquinone dyes is indicated, and its limitations with reference to the explanation or prediction of colors discussed. In making the measurements, the basic dyes were dissolved in dil. acid, and the acid or phenolic dyes in dil. alk. in order to develop the colors fully. The reduction products of the flavones were prepd. (in soln.) according to *C. A.* 8, 1748.

M. HEIDELBERGER.

Effect of additional auxochromes on the color of dyes. I. Phthalein and benzein dyes. VISHNU R. MISHRI AND EDWIN R. WATSON. Dacca. *J. Chem. Soc.* 107, 1579-82 (1915).—Fluorescein (A), gallein (B), the dihydroxyfluorescein (C) from $C_6H_4(CO)_2O$ and 1,3,4- $C_6H_3(OH)_3$ (D), resorcinolbenzein (E), pyrogallolbenzein (F), and hydroxyquinolbenzein (G) (prepd. according to Ghosh and W., *C. A.* 8, 3367) were examd. spectroscopically in alc. soln. before and after the addition of KOH. The results are given in a series of curves. In both groups of dyes the effect of increasing the number of auxochrome groups was to widen the absorption band in the visible part of the spectrum and to shift the max. a little towards the red, the effect being more marked in (B) and (F) than in the dyes derived from (D). Addition of alkali enhances the effect and makes the band shallower. The results are interpreted as being due to 2 bands at about $\lambda 5000$ and 5800 , resp., their relative strengths being different in the different cases. The bands and the max. are not seen separately because the width of the bands is greater than the difference between their centers. In (A) and (E) with and without alkali and in (C) and (G) in neutral soln. only the band at $\lambda 5000$ is developed, but in alk. solns. of the latter 2 the 2nd band appears. This band is relatively most strongly developed in the pyrogallol derivs., and is favored by the occurrence of 2 OH groups *o*- to one another.

M. HEIDELBERGER.

Influence of constitution on the basic property of oxygen. I. BROJENDRA N. GHOSH. Univ. Coll., London. *J. Chem. Soc.* 107, 1588-1605 (1915).—A systematic investigation to throw light on the manner in which the basic property of O is controlled by the constitution of the mol. in which the O occurs. The present paper deals particularly with the influence of certain unsatd. groups on the additive capacity of O in a cyclic chain. The following types of 6-membered ring systems were examd.: $(CH_2)_6O$ (I), $O:(CH_2)_4:O$ (II), $C_6H_4.(CH_2)_2O$ (III), $C_6H_4O.(CH_2)_2O$ (IV), $O.(CH_2)_2O.(CO)_2$ (V), (VI), (VII), $O.C_6H_4O.CO.CH_3$ (VIII), $O.C_6H_4O.(CO)_2$ (IX),

(VI)

(VII)

(X)

(X), and $O.C_6H_4.CH:CH.CO$ (XI). Since Hofmann (*C. A.* 4, 1043, 2464) has shown

that $HClO_4$ is probably the most useful acid for the formation of stable salts with weak bases, this was used in every case and supplemented, when salt formation was observed, with the use of other acids. (I), (II) and (III) yielded no salts. (IV): 22 g.

α -C₆H₄(OH)₂ (A), 40 g. BrC₆H₄Br, 28 g. powdered, fused K₂CO₃, and 0.5 g. Cu bronze with a little glycerol were heated under a reflux 7-8 hrs. at 190-200°, made alk. with NaOH and distd. with steam. The distillate, containing oil, was extd. with CHCl₃ and this was washed with dil. alkali, dried, and concd. The portion of the residue b₇₁₇ 212-4° was used. Yield, 16 g., 66% of the theory, and double that obtained by Vorländer's original method (Ann. 280, 203(1894)). It is insol. in acids or alkalis and has d₄²⁰ 1.180; the mono-NO₂ deriv. was converted into *dinitrobenzodihydrodioxin* in HOAc with 1 mol. HNO₃ and excess H₂SO₄ on the H₂O bath for 2 hrs., needles, m. 133-4°. (IV) and an excess of HNO₃ and H₂SO₄ at room temp. for 1 hr. gave *trinitrobenzodihydrodioxin*, needles, m. 155°. (IV) in boiling HOAc with 1 mol. Br gave a *mono-bromo derivative*, b₇₁₄ 275-6°, the Br being stable to boiling with alc. KOH; with an excess of Br there is formed the *dibromo derivative*, needles, m. 138°. (V): Prepd. from (COCl)₂ and HOC₆H₄OH in C₆H₅N; *dihydrochloride*, using the concd. acid and evapg. *in vacuo* over KOH, m. 152°; *dihydrobromide*, not very stable, m. 132° (decompn.); *dipicrate*, needles, m. 115°; *perchlorate*. (VI): 1 mol. each of HOC₁₀H₇Br and K₂CO₃ were heated in PhNO₂ with a little Cu bronze 10-12 hrs. at 190-200°, distd. with steam, and the residue washed with dil. NaOH and H₂O. Solvents extd. from this the difficultly sol. *di- α,β -naphthodioxin* (VI), pale yellow needles, m. 184-5°; yield, small; *ferrichloride*, from dry Et₂O solns., green, decomp. on heating; *dipicrate*, in PhH soln., chocolate needles, m. 156°; *diperchlorate*, from (VI) in HOAc and HClO₄ (d. 1.7), purple needles. (VII): 1 mol. each of 1,2,3-C₆H₃(OH)₃ and 2,3-dichloro- α -naphthoquinone in pure, dry C₆H₅N were heated on the H₂O bath until a sample, on mixing with dil. H₂SO₄, gave a product free from Cl (about 5 hrs.). The soln. was poured into dil. H₂SO₄ and the ppt., *4-hydroxy-6,11-diketobenz- β,β -naphthodioxin*, recrystd. from HOAc, purple needles, m. 288°; *sodium salt*, insol.; *ferrichloride*, green; *diperchlorate*, in HOAc, dark, cryst. powder, decomp. explosively on heating; *dihydrochloride*, brown, cryst. powder, m. 122°; *acetyl derivative*, pale pink needles, m. 154°. (VIII): 22 g. (A) and 4.6 g. Na in alc. and 25 g. ClCH₂CO₂Et were boiled 3 hrs. on the H₂O bath, with occasional shaking, and poured into H₂O; the resulting *ethyl o-hydroxyphenoxyacetate* forms needles, m. 48°, and when boiled under a reflux 1 hr. with concd. HCl, neutralized with Na₂CO₃, and extd. with Et₂O, yields *ketodihydrobenzodioxin* (VIII), prisms, m. 135°; *dipicrate*, needles, m. 125°; *dihydrochloride*, needles, m. 131°; *dinitrate*, from an HOAc soln. and HNO₃ (d. 1.2), needles, m. 113° (decompn.); *diperchlorate*, crystals with 0.5 H₂O, begins to decomp. at 100°. (IX): Prepd. like (V), since (A) and (CO₂H)₂ did not condense under the influence of dehydrating agents; *dipicrate*, needles, m. 112°; *disulfate*, needles, m. 271° (decompn.); *dihydrochloride*, needles, m. 175°; *diperchlorate*, crystals. (X): 7-Hydroxy-2-methyl-4-methylenebenzo- γ -pyrane was prepd. according to Bülow and Wagner (Ber. 34, 1198(1901)); *hydrobromide*, using the d. 1.49 acid, contains 0.5 H₂O, m. 217° (decompn.); *perchlorate*, yellow crystals with 2 H₂O, decomp. above 90°; *chloroplatinate*, plates with 2 H₂O; concd. HNO₃ causes decompn. (XI): Coumarin forms a *picrate*, needles, m. 112°; *sulfate*, needles, m. 155-6°; *perchlorate*, deliquescent, cryst. powder. 2-Thio-1,2-benzopyrane yields a *picrate*, needles, m. 118°; *hydrochloride*, in MeOH soln. at 0° with dry HCl, pale yellow needles, m. 62°; *perchlorate*, by evapn. *in vacuo* over KOH of a soln. in the acid. 4-Methylcoumarin (Peters and Simonis, C. A. 8, 1703) gives a *picrate*, needles, m. 65°; *perchlorate*. 4,6-Dimethylcoumarin; *picrate*, needles, m. 124°; *sulfate*, needles, m. 168-9°; *nitrate*, cryst. powder, m. 175°; *perchlorate*; *hydrobromide*, unstable at room temp. 6,7-Dimethylcoumarin (B); *picrate*, needles, m. 124°; *sulfate*, crystals, m. 135°; *nitrate*, needles, m. 140-1°; *perchlorate*. Equal wts. (B) and P₂S₅ fused a short time at the m. p., extd. with hot PhH and the soln. boiled 3 hrs. with a little Cu powder, gave 2-thio-6,7-dimethyl-1,2-benzopyrane, yellow needles, m. 159-60°; *oxime*, needles, m.

121.5°; *phenylhydrazone*, yellow needles, m. 168°; both of these are, of course, the same as the compds. derived from (B). 4,6,7-Trimethylcoumarin; *picrate*, needles, m. 105°; *nitrate*, m. 118° (decompn.); *sulfate*, m. 92°; *perchlorate*; *chloroplatinate*, seps. with 4 H₂O. 2-Thio-4,6,7-trimethyl-1,2-benzopyrane, yellow needles, m. 158-9°; *oxime*, faintly yellow needles, m. 179-80°; *phenylhydrazone*, yellow needles, m. 147°. 7-Hydroxycoumarin; *mercurichloride*, crystals, decomp. at a high temp.; *picrate*, needles, m. 108°; *hydrochloride*, may be obtained by passing dry HCl into a soln. of (A) and AcCH₂CO₂Et in HOAc, needles, unstable at room temp.; *sulfate*, needles, m. 175° (decompn.); *perchlorate*. 3-Acetylcoumarin; *semicarbazone*, needles, m. 231°; *picrate*, needles, m. 75°; *hydrochloride*, needles, m. 108° (decompn.); *perchlorate*. 4-Methyl-1,2- α -naphthopyrone (XII); *mercurichloride*; *picrate*, needles, m. 89°; *hydrochloride*, needles, m. 178° (decompn.); *sulfate*, deliquescent crystals, m. 62°; *nitrate*, m. 78°; *perchlorate*, deliquescent crystals. 2-Thio-4-methyl-1,2- α -naphthopyrone, yellow needles, m. 186°; *mercurichloride*; *picrate*, m. 167°; *perchlorate*. For comparison, benzodioxole (catechol methylene ether) was prepd. (preferably using CH₂Cl₂ instead of the iodide as given by Moureu (*Bull. soc. chim.* [3] 15, 654(1897)); d_{4}^{20} 1.0640, is not sol. in acids. O.(CH₂)₂.O.CH₂ also failed to give salts with acids. Conclusions: The possibility of

salt formation with special reagents has been disregarded, hence the results are to be taken only as relative. In the compds. containing only 1 cyclic O, only the unsatd. substances yielded salts, and to these may also be added fluorane and the flavones. In the series containing 2 cyclic O, only (II) and (IV) failed to give salts. It is therefore seen that the additive power of O in these compds. is increased by the entrance of acidic or negative groups, such as the C:C, C:O, C:S groups and the PhH and C₆H₅ nuclei, although a single PhH ring is not sufficient to confer basicity (cf. III and IV). Previous work on the hydroxyflavones and the unsatd. ketones ArCH:CHCOCH:-CHAr, which form salts, furnishes additional support to the relation herein advanced.

M. HEIDELBERGER.

Action of alkalis on the nitrosoamines of 4-piperidone derivatives. ERIC D. EVENS, EDGAR C. GIFFORD AND WALTER E. L. GRIFFITHS. Univ. Bristol. *J. Chem. Soc.* 107, 1673-7(1915).—Francis (C. A. 7, 1351) found that the nitrosoamine of 2,6-tetramethyl-4-piperidone (triacetonamine) is quant. converted into phorone, H₂C=, and N by the catalytic action of OH ions. This work was undertaken with the idea of prepg. further nitrosoamines for the examn. of this reaction and of studying the resulting products. Diacetonamine oxalate and aldehydes were condensed in boiling alc. until no more ppt. formed. The percentages below refer to the yields obtained; the nitrosoamines were prepd. from the oxalates in H₂O or dil. acids with NaNO₂ in almost quant. yields. Only the descriptions given below are recorded of the substances which were obtained: Isobutyldiacetonamine oxalate, 80%; nitrosoamine (A), m. 56°, not 51-2° (Kohn and Wenzel, *Monatsh.* 27, 981 (1906)); phenyldiacetonamine oxalate, 62%; nitrosoamine (B), m. 75°, not 66-8° (K. and W.); cinnamyldiacetonamine oxalate, 60%; nitrosoamine (C), m. 126°; isovaleryldiacetonamine oxalate, 60%; nitrosoamine, m. 59°; vinylldiacetonamine oxalate, 60%; nitrosoamine, m. 59° (not analyzed); anisyldiacetonamine oxalate, 50%; nitrosoamine (D), m. 74°; *p*-tolylldiacetonamine oxalate, 50%; nitrosoamine, oil; butyldiacetonamine oxalate, 42%; nitrosoamine, m. 44°; heptyldiacetonamine oxalate, 40%; nitrosoamine, oil; propyldiacetonamine oxalate, 26%; nitrosoamine, m. 28°. The nitrosoamines were expected to behave as that of triacetonamine when treated with alkalis in the absence of air, but only those compds. given below gave products which could be handled. (B), treated with a small amt. of NaOEt, gave an oil which partly crystd. The solid portion, recrystd. from alc., gave the compound (PhCH:CHCOCH:CM₂)₂, m. 88°. The oil, which slowly continued to deposit

small amts. of the solid, was probably a mixt. of monomer and dimer. (D) gave quant. a yellow oil which solidified, giving α -*p*-methoxyphenyl- ϵ -methyl- Δ^{ab} -hexadien- γ -one, $\text{MeOC}_6\text{H}_4\text{CH:CHCOCH:CMc}_3$, yellow plates, m. 56° . (C) yielded 85% of the theory of α -phenyl- η -methyl- Δ^{ar} -octatrien- ϵ -one, $\text{PhCH:CHCH:CHCOCH:CMc}_3$, yellow needles or plates, m. 87.5° ; with Br in CS_2 it gives a hexabromide, m. 160° . (A) gave in small yield, and not absolutely pure, β - η -dimethyl- Δ^{ar} -octadien- ϵ -one, $\text{Me}_2\text{C:CHCOCH:CHCHMc}_3$, oil, b₁₁ $93-8^\circ$; tetrabromide, m. $76-7^\circ$. M. HEIDELBERGER.

Simple hydroaromatic hydrocarbons, alcohols and ketones. K. v. AUWERS, R. HINTERSEBER AND W. TREPPMANN. Univ. Greifswald and Marburg. *Ann.* 410, 257-87(1915).—The following new detns. of physical constns. are reported: *Cyclohexane*, b₇₁₀ $80.0-80.2^\circ$, $d_4^{11.2}$ 0.7869, n_D 1.42910, n_D 1.43119, n_D 1.43668, n_D 1.44116 at 10.85° , EE -0.05 , -0.06 , 0%, -3% for α , D, $\beta - \alpha$, and $\gamma - \alpha$. *Cyclohexene*, b₇₁₀ $83-83.5^\circ$, $d_4^{15.6}$ 0.8143, n_D 1.44653, n_D 1.44921, n_D 1.45620, n_D 1.46194 at 15.1° , EE -0.24 , -0.26 , -4% , -4% for α , D, $\beta - \alpha$, and $\gamma - \alpha$. *Methenecyclohexane* (twice distd. over Na), b₇₁₀ $100.5-1.3^\circ$, $d_4^{15.6}$ 0.8035, n_D 1.44934, n_D 1.45222, n_D 1.45958, n_D 1.46568 at 15.5° . EE 0.34, 0.34, 7%, 6%, for α , D, $\beta - \alpha$, and $\gamma - \alpha$. *3,5-Dimethylcyclohexyl bromide*, b₇₁₀ $92-4^\circ$, d_4^{18} 1.2076, n_D 1.48020, n_D 1.48321, n_D 1.49033, n_D 1.49626 at 18.2° , EE 0.31, 0.32, 9%, 6%, for α , D, $\beta - \alpha$, and $\gamma - \alpha$. The bromide is best converted into the cyclohexane by heating a mixt. of 16 g. bromide, 70 cc. 96% alc., 32 g. Zn dust and the same amt. of sand 10 hrs. at 100° . The product is purified by shaking 2 days with ice-cold KMnO_4 , distg., adding Br to a permanent color and again distg. *1,3-Dimethylcyclohexane*, b. $118-20^\circ$, $d_4^{20.76}$ 0.7707, n_D 1.42276, n_D 1.42499, n_D 1.43947, n_D 1.43500 at 20.75° , EE 0.18, 0.20, 7%, and 3% for α , D, $\beta - \alpha$, and $\gamma - \alpha$. *1,2-Dimethylcyclohexene*, $d_4^{13.7}$ 0.8315, n_D 1.45906, n_D 1.46178, n_D 1.46908, n_D 1.47517 at 13.5° , EE -0.07 , -0.09 , 3%, 3% for α , D, $\beta - \alpha$, and $\gamma - \alpha$. *1,3-Dimethyl-3-cyclohexene*, prepd. from the alc. and P_2O_5 and twice distd. over Na, b₇₁₀ $124-6^\circ$, $d_4^{22.6}$ 0.7998, n_D 1.44263, n_D 1.44533, n_D 1.45215, n_D 1.45795 at 22.4° , EE 0.16, 0.16, 3%, 3% for α , D, $\beta - \alpha$, and $\gamma - \alpha$. *1,3-Dimethyl-5-cyclohexene*, b₇₁₀ $126-7^\circ$ (yield, 80%), $d_4^{21.1}$ 0.797, n_D 1.44086, n_D 1.44361, n_D 1.45020, n_D 1.45587, EE 0.16, 0.16, 2%, 2% for α , D, $\beta - \alpha$, and $\gamma - \alpha$. The constitution follows from the facts that it forms a nitrosochloride with difficulty and that upon oxidation with KMnO_4 it yields, not a keto acid, but an oil (dibasic acid), b₁₁ $210-220^\circ$, probably α, γ -dimethyladipic acid. *1,4-Dimethylcyclohexene*, b₇₁₀ $124-6^\circ$, d_4^{22} 0.7989, n_D 1.44112, n_D 1.44372, n_D 1.45056, n_D 1.45626 at 22° , EE 0.12, 0.10, 2%, 2% for α , D, $\beta - \alpha$, and $\gamma - \alpha$. *Ethenecyclohexane*, b₇₁₀ $136-6.4^\circ$, $d_4^{17.6}$ 0.8237, n_D 1.46094, n_D 1.46389, n_D 1.47139, n_D 1.47773 at 17.6° , EE 0.35, 0.36, 9%, 10% for α , D, $\beta - \alpha$, and $\gamma - \alpha$. *1,3,5-Trimethylcyclohexene*, b. $140.5-42^\circ$, $d_4^{13.6}$ 0.8031, n_D 1.44604, n_D 1.44909, n_D 1.45591, n_D 1.46155 at 13.5° , EE 0.27, 0.29, 7%, 5% for α , D, $\beta - \alpha$, and $\gamma - \alpha$. *1,3,5-Trimethylcyclohexyl chloride*, prepd. by satg. trimethylcyclohexene in AcOH with HCl with cooling, oil, b₇₁₀ $68-9^\circ$, $d_4^{16.2}$ 0.9219, n_D 1.45182, n_D 1.45455, n_D 1.46035, n_D 1.46555 at 15.2° , EE 0.47, 0.49, 6%, 5% for α , D, $\beta - \alpha$, and $\gamma - \alpha$. *Bromide*, b₇₁₀ $95-8^\circ$, $d_4^{11.1}$ 1.1749, n_D 1.47951, n_D 1.48280, n_D 1.48971, n_D 1.49532 at 11.1° , EE 0.28, 0.31, 10% (?), 5% for α , D, $\beta - \alpha$, and $\gamma - \alpha$. Attempts to reduce these compds. to the hexane were unsuccessful. *1,3-Dimethyl-5-methenecyclohexane*, prepd. by heating 1,3-dimethylcyclohexylidene-5-acetic acid in a stream of CO_2 for 2 hrs., mobile oil, b₇₁₀ $135-6^\circ$. It does not form a nitrosochloride. Upon oxidation with KMnO_4 it yields 1,3-dimethyl-5-cyclohexanone (identified as the semicarbazone); $d_4^{14.6}$ 0.7918, n_D 1.44334, n_D 1.44628, n_D 1.45313, n_D 1.45917 at 14.6° , EE 0.57, 0.60, 8%, 9% for α , D, $\beta - \alpha$, and $\gamma - \alpha$. *Cyclohexanol*, m. 23° , d_4^{27} 0.9373, n_D 1.45902, n_D 1.46035, n_D 1.46685, n_D 1.47146 at 37° , EE 0.07, 0.05, 0%, -1% for α , D, $\beta - \alpha$, and $\gamma - \alpha$. *1-Methylcyclohexanol*, m. $24-5^\circ$, b₇₁₀ 56.5° , $d_4^{24.66}$ 0.9251, n_D 1.4531, n_D

1.45874, n_D 1.46428, n_T 1.46908 at 24.65°, EZ —0.14, —0.13, 0%, 0% for α , D, β — α , and γ — α . *1-Methyl-2-cyclohexanol*, b_{16} 167.4–7.6°, $d_4^{13.4}$ 0.9333, n_D 1.46352, n_D 1.46585, n_T 1.47180, n_T 1.47665 at 13.4°, EZ 0.00, 0.00, 2%, 1% for α , D, β — α , and γ — α . *1-Methyl-3-cyclohexanol*, b_{14} 76–8°, $d_4^{24.3}$ 0.9182, n_D 1.45217, n_D 1.45444, n_T 1.46031, n_T 1.46502 at 25.5°, EZ —0.02, —0.02, 4%, 2% for α , D, β — α , and γ — α . *1-Methyl-4-cyclohexanol*, b_{12} 74.7–75.2°, $d_4^{22.5}$ 0.9183, n_D 1.45366, n_D 1.45594, n_T 1.46160, n_T 1.46651 at 22.5°, EZ 0.01, 0.02, 4%, 2% for α , D, β — α , and γ — α . *1,3-Dimethyl-3-cyclohexanol*, b_{11} 79–81°, $d_4^{22.9}$ 0.9028, n_D 1.45177, n_D 1.4514, n_T 1.45984, n_T 1.46463 at 22.9°, EZ —0.02, —0.02, 4%, 1% for α , D, β — α , and γ — α . *1,4-Dimethyl-4-cyclohexanol*, b_{11} 70–2°, $d_4^{23.9}$ 0.9060, n_D 1.45317, n_D 1.45534, n_T 1.46141, n_T 1.46622 at 23.9°, EZ —0.05, —0.05, 5%, 2% for α , D, β — α , and γ — α . *1,3-Dimethyl-5-cyclohexanol*, 2 samples were examd.; the 1st b , 81.5–2°, b_{18} 89°, b_{17} 181°, $d_4^{18.65}$ 0.8996, n_D 1.45354, n_D 1.45601, n_T 1.46181, n_T 1.46651 at 18.55°; the 2nd, m , 36–8°, long glistening needles, $d_4^{18.9}$ 0.8806, n_D 1.44440, n_D 1.44700, n_T 1.45238, n_T 1.45727 at 38.4°, EZ 0.21, 0.23, 5%, 2% for α , D, β — α , and γ — α . *Acetate*, b_{11} 84–5°, $d_4^{20.2}$ 0.9277, n_D 1.43526, n_D 1.43758, n_T 1.44312, n_T 1.44771 at 20.2°, EZ 0.15, 0.15, 3%, 1% for α , D, β — α , and γ — α . *1,3,5-Trimethyl-5-cyclohexanol*: 2 samples were used, 1 prepd. from the liquid, the other from the solid dimethylcyclohexanol. (1) b_{18} 83–5°, $d_4^{24.7}$ 0.8861, n_D 1.44865, n_D 1.45115, n_T 1.45674, n_T 1.46160 at 24.7°; (2) b_{18} 82–3°, $d_4^{18.8}$ 0.8876, n_D 1.45108, n_D 1.45371, n_T 1.45921, n_T 1.46422 at 16.3°, EZ 0.13, 0.13, 5%, 2% for α , D, β — α , and γ — α . *Cyclopentanone*, b_{18} 23.2–3.6°, d_4^{17} 0.9516, n_D 1.43587, n_D 1.43817, n_T 1.44390, n_T 1.44867 at 17.3°, EZ 0.11, 0.11, 3%, 0% for α , D, β — α , and γ — α . *Cyclohexanone*, b , 156.6–6.8°, $d_4^{15.3}$ 0.9503, n_D 1.45024, n_D 1.45261, n_T 1.45859, n_T 1.46370 at 15.3°, EZ 0.18, 0.18, 2%, 1% for α , D, β — α , and γ — α . *Cycloheptanone*, $d_4^{21.5}$ 0.9498, n_D 1.45801, n_D 1.46027, n_T 1.46646, n_T 1.47149 at 21.9°, EZ 0.03, 0.01, 0%, —1% for α , D, β — α , and γ — α . *1-Methyl-2-cyclohexanone*, b_{110} 167°, $d_4^{14.6}$ 0.9300, n_D 1.44827, n_D 1.45049, n_T 1.45653, n_T 1.46135 at 14.6°, EZ 0.09, 0.07, 0%, —1% for α , D, β — α , and γ — α . *1-Methyl-3-cyclohexanone*, b_{18} 60–60.2°, $d_4^{26.15}$ 0.9139, n_D 1.44092, n_D 1.44313, n_T 1.44914, n_T 1.45394 at 25.15°, EZ 0.18, 0.17, 2%, 0% for α , D, β — α , and γ — α . *1-Methyl-4-cyclohexanone*, $b_{10.8}$ 55.8–6.4°, $d_4^{24.4}$ 0.9119, n_D 1.44092, n_D 1.44322, n_T 1.44918, n_T 1.45413 at 24.4°, EZ 0.24, 0.23, 2%, 2% for α , D, β — α , and γ — α . *1,3-Dimethyl-5-cyclohexanone*, b 180°, $d_4^{13.2}$ 0.8967, n_D 1.44272, n_D 1.44542, n_T 1.45118, n_T 1.45590 at 13.2° (1 of the 5 sets given), EZ 0.33, 0.35, 5%, 4% for α , D, β — α , and γ — α .

Relation between the constitution and physical properties of isomeric and homologous hydroaromatic compounds. K. v. AUWERS. *Ann.* 410, 287–336(1915).—A general discussion of the question, in which all the values for the hydroaromatic compds., with a 6-membered ring (cyclohexanes, cyclohexenes, cyclohexanols, cyclohexanones and their Me derivs.), are collected together and the most probable values indicated. Certain general conclusions are also drawn. The b. p. of the satd. alcs. and ketones decreases with the approach of the Me group to the OH or keto group, while in the simple unsatd. hydrocarbons it is raised with the approach of the Me group to the double bond. The relative positions of the Me groups play a minor role. In the satd. hydrocarbons no definite regularity in the b. p. has been observed, though this may be due in part to faulty observations. The density increases, in general, with the introduction of the Me group into the mol. and with its approach to the double bond or to the OH or CO group. Where both influences are present the highest densities are found. The same general relations hold for the index of refraction, though they are not as pronounced. The mol. refraction of isomeric compds. of all 4 classes is the larger the farther sepd. the side chains are from one another and from the double bond.

or the OH or CO groups. The sym. compd. usually has a marked exaltation, while the unsym. has a normal index or a depression. The mol. dispersion is normal for all satd. and endocyclic unsatd. compds. Methene derivs. have lower b. p. and smaller densities than the isomeric compds. with endocyclic double bonds, but have about the same index of refraction. With cyclohexanes and cyclohexenes the introduction of a Me group regularly produces an increase of the b. p., though the possibility that higher homologs boil lower is not excluded. This is seen in some of the alcs. and ketones. The density of O-containing compds. decreases with the number of Me groups introduced, though there are exceptions. In the satd. hydrocarbons the differences in the densities are very slight. No rule can be given concerning the index of refraction of homologous compds. The b. p. of satd. hydroaromatic hydrocarbons are lower than those of the analogous cyclohexenes; on the other hand the H-rich alcs. boil higher than the H-poorer ketones. This is also true of the density, the cyclohexenes being heavier than the cyclohexanes, while the ketones are lighter than the alcs. The index of refraction increases from satd. to unsatd. hydrocarbons and decreases by the change of the alc. into the corresponding ketone.

C. J. WEST.

Oxidation of uric acid in alkaline solution. III. ROBERT BEHREND AND RUDOLF ZIEGER. Hannover. *Ann.* 410, 337-73 (1915).—Behrend supposed a compd. of the type of uric acid glycol as an intermediate oxidation product of uric acid in order to explain the production of β -methylallantoin from 1- and 7-methyluric acid (*Ann.* 333, 141; 343, 151). This compd. has been prepd. by Biltz (*C. A.* 4, 2644; 6, 2620; 8, 1430) and, since it does not yield allantoin nor uroxic acid when treated with alkali, it is not the desired intermediate product. A second possible explanation of the oxidation is that the uric acid mol. is split at the 1,6-position:

Best yields of uric acid glycol are obtained by neutralizing the acid formed in the reaction with 10% Na_2CO_3 . An isomeric glycol was not obtained. 8.56 g. alloxan tetrahydrate, 24 cc. H_2O , 6.4 g. $\text{CO}(\text{HNH}_2)_2$ and 10 cc. 36% HCl were heated 4 min. until boiling ensued, filtered from alloxantin the next day and then allowed to evaporate at room temp., giving 4.12 g. pure *alloxanic acid urea*, 4-sided prisms, decomp. $155-6^\circ$. 17.5 cc. 50% hot EtOH dissolves 10 g. substance. Heated at 102° for some time the compd. gradually decomps., more rapidly if $\text{CO}(\text{NH}_2)_2$ is added. *Acid calcium salt*, $\text{Ca}(\text{C}_4\text{H}_3\text{O}_4\text{N}_3)_2 \cdot 6\text{H}_2\text{O}$, prepd. by dissolving the substance in a little more than 1 equiv. of warm 10% CaCl_2 and adding an equiv. of 20% AcONa , lancet-like needles or prisms. *Neutral calcium salt*, short rhombic prisms, obtained by treating the CaCl_2 soln. with NH_4OH , contains 5 mols. H_2O . Uric acid glycol gives the same product when warmed to 50° with 35% HCl . *Urea alloxan*, from the components in H_2O , decomp. 117° or 134° , easily sol. in H_2O , and probably is a salt-like compd. It gives uric acid glycol when heated with H_2O , AcOH or when heated to $95-100^\circ$. Ac_2O gives an *anhydride of urea alloxan*, microscopical needles, decomp. $185-6^\circ$. *Potassium alloxan*, from 2.14 g. alloxan tetrahydrate in 5 cc. H_2O and 0.74 cc. 50% KOH , light red, decomp. 235° . It is sol. in about 20 parts H_2O , giving a soln. alk. to litmus. Upon standing it gives K alloxanate. *Alloxanic acid urea* is most easily obtained by the action of 21.4 g. alloxan

tetrahydrate in 50 cc. H_2O and 6.2 g. KOH, allowing the mixt. to stand overnight, filtering, adding 7 g. $CO(NH_2)_2$ and 10 cc. 36% HCl and allowing to evap. at room temp. Alloxanic acid is easily obtained from the K salt (above), by decomp. with 10–20% HCl, evapg. and extg. with Et_2O or EtOH. With $SOCl_2$ at 40–50° for 2 hrs., the *chloride* is formed which, with MeOH, gives *methyl alloxanate*, pointed prisms from AcOEt, decomp. 175–6°. The aq. soln. reacts strongly acid to litmus and decomps. bicarbonates. The ester does not condense with $CO(NH_2)_2$. Alloxanic acid urea and Ac_2O give allantoin. Various expts. on the oxidation of uric acid are reported with the yields of allantoin.

C. J. WEST.

Sulfonation of benzene. II. GERHERD MOHRMANN. *Ann.* 410, 373–85 (1915). —100 g. H_2SO_4 , d. 1.84, were heated to 235–45°, and the vapors of 25 g. C_6H_6 passed through until completely absorbed. The sulfonic acids were changed into the Na salts, which were obtained in 3–4 fractions by concn. These were dried at 150° and changed into the chlorides. The 2 chlorides were sepd. by crystn. from ligroin. The effect of various catalyzers was detd. The figures given represent the yield of *p*- $C_6H_4(SO_2Cl)_2$, which with the yield of the *m*-compd., make 100%. No catalyzer, 1.4; 1 g. Hg, 32.6, 30.4; 1.8 g. dry $CdSO_4$, 4.2, 5.2; 1 g. Al, 14.6, 13.9; 1.5 g. Pb, 9.7 (9.5% monochloride was also obtained); 1.3 g. As_2O_3 , 9.3; 1.1 g. Bi_2O_3 , 8.7, 9.4; 1.4 g. Se, only monochloride obtained; 2.7 g. $MnSO_4$, 2.7%.

Hydrazides and azides of organic acids. XXXII. The hydrazides and azides of succinic acid. THEODOR CURTIUS. *J. prakt. Chem.* 92, 74–107 (1915); cf. C. A. 9, 2765.—I. (With ERNST MUCKERMANN.) Succinyl dihydrazide (a), $(CH_2CONHNH_2)_2$ (Schöfer and Schwan, *J. prakt. Chem.* 51, 190 (1895)) and succinyl diazide (b), $(CH_2CON_3)_2$ (Curtius, *J. prakt. Chem.* 52, 221 (1895)) are the only members of this series which have been previously prepd. *Hydrazinosuccinic acid* (c), $NH_2NHCOCH_2CH_2CO_2H$, is obtained in the form of its *hydrazine salt* (d), needles from abs. alc., stout prisms from 90% alc., m. 104°, when 8 g. $(CH_3)_2(CO_2Et)CO_2H$ (e) is allowed to stand several days with 6 g. $N_2H_4 \cdot H_2O$ (f) *in vacuo* over H_2SO_4 ; the aq. soln. reacts weakly acid. Contrary to the statements of Heintz, *Pogg. Ann.* 108, 86 (1859), (e) cannot

be distd. under ordinary pressure without partial decompn. into $CH_3CO.O.CO.CH_3$. On attempting to prep. (c) from the Ba salt of (e) and $(N_2H_5)_2SO_4$, (a) is formed; *di-benzal derivative*, a voluminous ppt. m. 223–4° on crystg. from alc. *Hydrazine succinamate* (g), from $NH_2COCH_2CH_2CO_2H$ (h) and 1 mol. (f), small crystals from abs. alc., m. 113°; the aq. soln. is neutral and gives with BzH ($PhCH:N$)₂ (i) in theoretical amt. When (h) is treated with 2 mols. (f) at ordinary temp., a *hydrazine salt* (j) of (c), is formed, large well-formed crystals, m. 122–3°, which crumble in the air; the aq. soln. is neutral and reduces NH_4AgNO_3 on warming, but not in the cold. When (d) in 15–20 parts H_2O is shaken well with 2 parts BzH, then heated to boiling and filtered hot from (i), *benzalhydrazinosuccinic acid* (k), $PhCH:NHNHCOCH_2CH_2CO_2H$, seps., leaves from H_2O or alc., m. 164°; it may also be obtained from equal parts of (i) and BzH in 20 parts H_2O and is sepd. from traces of (i) by washing with alc. and Et_2O ; long heating with dild. alc. gives (i) and $(CH_3CO_2H)_2$ while hot dil. acids decomp. it with the formation of BzH, N_2H_4 and $(CH_3CO_2H)_2$. When *o*- HOC_6H_4CHO is condensed with (d), heated to boiling, filtered from *o*-($HOC_6H_4CH:N$)₂ and then cooled, *o*-hydroxybenzalhydrazinosuccinic acid seps. as a flocculent ppt. m. 193°. *m*-Nitrobenzalhydrazinosuccinic acid, from *m*- $NO_2C_6H_4CHO$ and (d), bright yellow crystals, m. 207°; *m*-($NO_2C_6H_4CH:N$)₂, which is also formed, is sepd. as in the previous cases. *Acetonehydrazinosuccinic acid*, formed when (d) is heated in Me_2CO , cryst. powder, m. 161°; it was not obtained pure. *Benzoylhydrazinosuccinic acid*, $BzNHNHCOCH_2CH_2CO_2H$, is formed when (f) is subjected to the Baumann and Schotten reaction; columnar prisms, m.

175°. *Asidosuccinic acid* (j), $\text{N}_2\text{COCH}_2\text{CH}_2\text{CO}_2\text{H}$, is formed when 10 g. (j) in H_2O is treated below 0° with 5 g. NaNO_2 in concd. aq. soln., covered with Et_2O , acidified with the calcd. amt. of H_2SO_4 , the Et_2O layer sepd. and evapd. *in vacuo* at room temp.; cryst. residue, which explodes weakly on heating; it is also obtained, but in very small quantity, when (d) is similarly treated with NaNO_2 . In both cases, *hydrasidisuccinic acid* (m), $(\text{HO}_2\text{C}.\text{CH}_2\text{CH}_2\text{CONH})_2$, seps. from the aq. solns. remaining after removal of the Et_2O layer; leaves from H_2O , m. 212° with the effervescence; liberates CO_2 from Na_2CO_3 ; (m) may also be prepd. by the action of I on (j) in alc.; *ammonium salt*, radiating needles; *silver salt*, amorphous powder; *diethyl ester* (n), from the Ag salt + EtI , needles from Et_2O , m. $127-8^\circ$. (n) in alc. with 2 mols. (f) is converted into (a). When the dry Et_2O soln. of (b) is boiled with abs. alc. the *urethan* (o), $\text{EtO}_2\text{C}.\text{NHCH}_2\text{CH}_2\text{CO}_2\text{H}$ (?) is obtained as an oil; the yield is small and the product impure. With the object of converting (o) into the β -amino acid, $\text{HCl}.\text{NH}_2\text{CH}_2\text{CH}_2\text{CO}_2\text{Et}$, (o) was treated with alc. HCl in the cold and also at 100° . In neither case could the ester hydrochloride be isolated; NH_3 was split off and the residue gave a product with PhSO_2Cl which m.

175°. When $\text{CH}_2.\text{CO}.\text{NH}.\text{CO}.\text{CH}_2$ (p) in alc. is boiled with 2 mols. (f), (a) is formed, but when only 1 mol. (f) is used and the mixt. not warmed, *succinamyl hydrazide* (q), $\text{NH}_2\text{COCH}_2\text{CH}_2\text{CONHNH}_2$, seps. on standing; fine needles from abs. alc. which shrivel at 138° and m. 145° with effervescence; *dihydrochloride*, unstable ppt. when concd. alc. HCl is added to an aq. soln., m. $115-6^\circ$ with lively effervescence; *benzyl derivative*, crystals from alc. m. 194° ; *benzoyl derivative*, leaves from abs. alc., m. 192° (decompr.). *Hydrazine ethyl sulfate* is produced when 50 g. EtOH is heated $1/4$ hr. with 326 g. H_2SO_4 , then dild. with H_2O , satd. with BaCO_3 , filtered from BaSO_4 , treated with $(\text{N}_2\text{H}_5)_2\text{SO}_4$ until pptn. is complete, filtered and evapd. to dryness; on standing, the resulting sirup solidifies in long hygroscopic needles, m. 51° . II. (With KARL HOCHSCHWENDER and HERMANN THIERMANN.) When 60 g. $(\text{CH}_3\text{CO}_2\text{Et})_2$ in 90 cc. abs. alc. are heated 4 hrs. at $120-30^\circ$ with 9 g. (f), then filtered from 8-9 g. (a) and evapd. *in vacuo* at 40° ,

N-aminosuccinimide (r), $\text{CH}_2.\text{CO}.\text{N}(\text{NH}_2).\text{CO}.\text{CH}_2$, is formed as a very hygroscopic solid which deliquesces in the air and is best identified by its *benzyl derivative* (s), long needles from abs. alc. m. $172-3^\circ$; *hydrochloride*, pptd. from alc. soln. by HCl in Et_2O , cryst. ppt. decomps. 150° but does not m. to a clear oil below 280° ; *diacetyl derivative*, fine needles from ligroin, m. $69-70^\circ$. When a soln. of (r) in NaOH (1:4) is acidified with dil. acids, an insol. amorphous substance, m. 255° , seps., from which N_2H_4 is split off on warming with H_2SO_4 ; this same product is likewise formed when (r) is heated alone and will be further investigated. With HgO (r) gives a red color, with the evolution of a gas; rubbed with (f) at 0° , it is converted into (a). The hydrochloride (t), with

NaNO_2 , gives $\text{CH}_2.\text{CO}.\text{NH}.\text{CO}.\text{CH}_2$. When $\text{EtO}_2\text{C}(\text{CH}_3)_2\text{CO}_2\text{Et}$ is treated with (f) no compd. similar to (r) is produced, only the known dihydrazide. (a) warmed in aq. soln. partially decomps. into N_2H_4 , (r) and (c); attempts to convert (a) into (r) by means of Br or I were unsuccessful.

NORMAN A. SHEPARD.

Simple and mixed alkyl phosphates. W. A. DRUSHEL. Yale Univ. *Am. J. Sci.* 30, 643-8(1915).— Me_3PO_4 , Et_3PO_4 , Pr_3PO_4 , $(\text{iso-Bu})_3\text{PO}_4$, Me_2EtPO_4 , Me_2PrPO_4 , MePr_2PO_4 , Et_2PrPO_4 , EtPr_2PO_4 , were prepd. by treating the Na alcoholates with POCl_3 in abs. Et_2O . All the alkyl groups are hydrolyzed by $\text{Ba}(\text{OH})_2$ at room temp., although the 1st is much more easily attacked than the 2nd and 3d. In mixed alkyl phosphates the hydrolysis product contains both types of dialkyl phosphoric acids, $\text{HRR}'\text{PO}_4$ and HR_2PO_4 with the first type largely in excess. The b. p. (at reduced pressures), densities and solubilities in H_2O of the esters are given.

R. L. SIBLEY.

Some new organic compounds of vanadium. A. T. MERTES AND HERMAN FLECK. *J. Ind. Eng. Chem.* 7, 1037-8 (1915).— VCl_4 in C_6H_6 soln. reacts with NH_3 and its derivs., apparently forming mol. compds. containing 3-6 mols. of the NH_3 deriv. combined with 1 mol. VCl_4 . The methods of detg. V and Cl are described. Compds. (not named and properties not given) corresponding approx. to the following formulas were prepd.: $4\text{PhNH}_2 \cdot \text{VCl}_4$, $4\text{PhNMe}_2 \cdot \text{VCl}_4$, $4\text{PhNHNH}_2 \cdot \text{VCl}_4$, $4\text{MeC}_6\text{H}_4\text{NH}_2 \cdot \text{VCl}_4$, $3\text{MeC}_6\text{H}_4\text{NH}_2 \cdot \text{VCl}_4$, $4\text{NH}_3 \cdot \text{VCl}_4 \cdot 4\text{H}_2\text{O}$, $5\text{NH}_3 \cdot \text{VCl}_4 \cdot 3\text{H}_2\text{O}$, $6\text{MeNH}_2 \cdot \text{VCl}_4 \cdot \text{H}_2\text{O}$, $3\text{Ph}_2\text{NH} \cdot 2\text{VCl}_4$. C_6H_6 after 6 weeks gave a product which M. and F. represent by the formula $\text{C}_6\text{H}_5 \cdot 2\text{VCl}_3$; shorter time gave $\text{C}_6\text{H}_5\text{V}_2\text{Cl}_5$. With anthracene was obtained $\text{C}_{14}\text{H}_{10} \cdot 2(\text{C}_6\text{H}_5 \cdot \text{V}_2\text{Cl}_5)$.

R. L. SIBLEY.

The crystal form of phenylglyceric acid $\text{C}_6\text{H}_5\text{C}(\text{OH})\text{HC}(\text{OH})\text{HCOOH}$ and its active components. V. M. GOLDSCHMIDT. Kristiania. *Z. Krist. Min.* 55, 123-31 (1915).—The active forms of phenylglyceric acid cryst. in the sphenoidal class of the monoclinic system; they have equal angles (tabulated) but are enantiomorphic. The so-called racemic acid is a microscopic intergrowth of both active compds. but belongs to the prismatic class of monoclinic system. The m. p. of the active components is $164-165^\circ$, while that of the racemic form is 141° . Solns. of the inactive antipodes gave mechanically separable conglomerates of right and left crystals, pseudo-racemic crystals consisting of sub-microscopic portions of right and left substances, and real racemic crystals, i. e., crystals formed by the chem. union of both antipodes. The pseudo-racemic substances cannot be sepd. crystallographically but may be sepd. by their thermodynamic properties. The racemic crystals are divided into (a), pseudo-racemic mixed crystals consisting of an isomorphous mixt. of equal parts of right and left substances which have a continuous m. curve (example, camphoroxime which occurs as cubic crystals), (b), pseudo-racemic conglomerates which are lamellar intergrowths of equal parts of right and left substances that give seemingly homogeneous crystals regardless of whether the lamella are macro-, micro-, or sub-microscopic, and whose m. curve is thermodynamically like that of the conglomerates.

A. WANDTKE.

The electron theory in organic chemistry. N. P. McCLELLAND. Cambridge. *Phil. Mag.* 30, 665-75 (1915); cf. *C. A.* 9, 882.—On the theory that the formation of a valency bond between two atoms consists in the removal of one electron from the external ring of each atom to form a new orbit of rotation about the line joining the two atomic nuclei, M. suggests that the absorption of infra-red light is effected by the electrons in this inter-atomic valency orbit, while ultraviolet absorption is due to the remaining "unsatd." electrons in the external rings of the atoms. All compds. containing the C-H linkage have similar infra-red absorption bands. Although a single atom containing a rotating unsatd. electron, as in methylene or CH_2 , is not stable, two such electron orbits have a stabilizing action on each other which is analogous to mutual elec. inductance. Hence C_2H_4 is stable. When the induction effect is small the two electron orbits do not affect each other's absorption bands or chem. reactivity. Thus PhCH_2NH_2 resembles the aliphatic amines and shows the C_6H_5 absorption band; while, owing to the induction effect, PhNH_2 is different in both respects. Among similar compds. a lower frequency absorption corresponds to greater reactivity, e. g., the aldehydes and ketones. In a conjugate system of unsatd. bonds the two central atoms stabilize each other by the induction effect but this cannot affect the first and fourth atoms, so that these are active, as in Thiele's theory. An unsatd. group adjacent to a C-Br bond makes the latter more stable, and similarly makes a C-H bond less stable; but these cannot be predicted from the theory. The theory is shown to be consistent with stereochemistry. A structure for C_6H_6 is proposed in which the C atoms are arranged at the corners of an octahedron formed by alternately raising and de-

pressing the C atoms of the Kekulé ring from the plane of the ring. The connecting valence electrons revolve about centers in the mean plane, while the free valency electrons revolve in planes parallel to it, with the H atoms disposed outside the C's.

G. L. WENDT.

Preparation of optically active fats. III. Synthesis of the four possible optically active butyrins. Inversion of the three-carbon system into the optical antipodes. EMIL ABDERHALDEN AND EGON EICHWALD. Univ. Halle a/S. *Ber.* 48, 1847-65 (1915); cf. *C. A.* 9, 310, 1058.—As was forecast in the earlier papers, it has been found possible, by improving the methods, to obtain material of higher rotation in the prepn. of active epihydrin alc. and aminoglycerol, but the attempts to obtain active aminoglycerol and fats by a shorter method from active dibromohydrin have not all been successful. Amination of *d*-dibromohydrin (replacement of both Br atoms by NH_2) never gave an active product, probably because the Br is not directly replaced but HBr is first split off, with formation of a glycidic ring which then adds NH_3 . Treatment of active epibromohydrin with alc. KI, with KOAc or with Ag or alkali salts of fatty acids also led to inactivation, so that the methods used chiefly by Grün for the prepn. of fats of a definite constitution lose much of their value in proving structures. A method free from doubt consists of treating the hydrochlorides or sulfates of the aminoglycerols with excess of fatty acid chlorides, removing the NH_2 with NaNO_2 and fractionating in a high vacuum to remove the chlorinated glycerols which are always formed as a result of the violent reaction. Even in a high vacuum, however, distn. of active fats often results in complete inactivation, so that it is better to esterify the aminoglycerol in concd. H_2SO_4 with excess of fatty acid and then treat with NaNO_2 . *L*-Epihydrin alc., which is *L*-rotatory in substance, gives by addition of PrCO_2H a monobutyryn which is *d*-rotatory in alc., while on the other hand it yields a *d*-aminoglycerol giving a butyryn which is *L*-rotatory in alc. Although the 2 butyrins cannot be directly compared, as 1 is a mono- and the other a dibutyryn, there is no doubt that an optical inversion has occurred. The ease with which compds. of both the *d*- and *L*-series are formed probably is the reason why no active fats have thus far been found in nature, and it is also very probable that the lipolytic ferments are not specifically adapted to 1 of the possible configurations. As a genetic designation is meaningless in the case of the fats, the prefixes *d*- and *L*- are now used according as the particular compd. is *d*- or *L*-rotatory in substance or in alc., thus involving some changes in the earlier designations. It has been found that if aminodibromopropane *d*-tartrate is heated some time with H_2O on the H_2O bath, HBr is split off and there is considerable loss, so that in recrystg. large amts. (8 kg.) the concn. must be effected *in vacuo*; smaller amts. (2-3 kg.) may be recrystd. on the H_2O bath by adding the required amt. of boiling H_2O and stirring vigorously until the salt dissolves; the latter is thus exposed only 5-10 min. to the higher temp. and the loss of HBr is insignificant. A *d*-epibromohydrin with $[\alpha]_D^{18} 23.06^\circ$ is obtained by slowly pouring, in the course of 5-10 min., 50 g. KOH in 100 cc. cold H_2O into 100 g. active dibromohydrin, at once extg. with Et_2O , drying with Na_2SO_4 , evapg. up to 60° , letting stand at this temp. for some time and distg. *in vacuo* at 40° . *d*-Dipropionyl- α -bromohydrin, from 2 g. *d*- α -bromohydrin ($[\alpha]_D^{18} 4.10^\circ$ in H_2O) and 6 g. $(\text{EtCO})_2\text{O}$, $[\alpha]_D^{18} -2.21^\circ$ in alc. *d*-Di-butyryl- α -bromohydrin, from *d*- α -bromohydrin and excess of PrCOCl , $[\alpha]_D^{18} -2.19^\circ$ in alc. *L*-Epihydrin alcohol (a) (formerly designated as the *d*-compd.), d. 1.1050, $[\alpha]_D^{18} -8.55^\circ$, is obtained in 38 g. yield from 110 g. *d*- α -bromohydrin, $[\alpha]_D^{18} 4.38^\circ$ in H_2O (prepd. by hydrolysis of the HCO deriv. with HCl and freed from HCl by twice evapg. the crude oil with a little alc. and finally heating 0.5 hr. *in vacuo* at 70°) poured into a little more than the calcd. amt. of KOH in the least possible cold alc. and neutralized after 24 hrs. to phenolph. with alc. HCl. From 38 g. of (a) is obtained 34 g.

d-aminoglycerol (*b*), $b_{D,1}$ 134°, $b_{D,18}$ 163° without racemization, $[\alpha]_D^{18}$ 2.42° in H_2O , 17.70° in dil. HCl. The following monoglycerides were prepd. in preliminary expts. from a *d*-(*a*) with $[\alpha]_D^{18}$ 4.02°, 1 g. of which with 1 mol. of the fatty acid was allowed to stand 2 weeks at 37°, treated with Et_2O (except in the case of the monoacetin, which is insol. in Et_2O), filtered, and freed from Et_2O , unchanged acid and (*a*) *in vacuo*. All the resulting fats except the monoformin were active; why the latter was inactive has not been detd. *l*- α -Monoacetin, -propionin, -butyrin, -valerin and -caproin showed $[\alpha]_D^{18}$ -1.14°, -0.83°, -0.63°, -0.530 and -0.40°, resp., in alc. *d*- α -Monobutyryn, from an (*a*) with $[\alpha]_D^{18}$ -8.55°, showed $[\alpha]_D^{18}$ 0.83°. An *l*- α , β -dibutyryn, still containing some Cl, with $[\alpha]_D^{18}$ -1.67° in alc., -1.86° in Et_2O , sapon. no. 632.4, is obtained from 1.5 g. (*b*) in alc. neutralized with alc. HCl, evapd. *in vacuo*, heated 0.5 hr. at 70° *in vacuo*, then 0.5 hr. longer with P_2O_5 in the receiver, then treated with 3 g. $PrCOCl$, poured into H_2O , filtered, treated cold with $NaNO_2$, extd. with Et_2O , washed with soda and dried with Na_2SO_4 ; fractionation in a high vacuum gives a product practically free from Cl but wholly inactive, $b_{D,1}$ 134-6°. When cooled mixts. of 5 g. (*b*) with 15 cc. $PrCO_2H$ and 10 cc. $PrCO_2H$ with 15 cc. concd. H_2SO_4 are brought together, heated 4 hrs. at 65° (protected with a $CaCl_2$ tube), allowed to stand 2-3 days, poured into 100 cc. ice H_2O , covered with Et_2O and treated with concd. aq. KOH, there is obtained 2 g. of *d*- γ -amino- α , β -dibutyryn, basic oil sol. in dil. acids, $[\alpha]_D^{18}$ 1.09° in dil. HCl, 0.47° in alc., at once converted in acids by $NaNO_2$ into *l*- α , β -dibutyryn (best obtained (4 g. yield) without isolating the NH_2 compd.), d. 1.0890, $[\alpha]_D^{18}$ -1.10° in substance, -2.31° in alc., the $[\alpha]$ and sapon. nos. varying somewhat in different preps. *l*- α , β -Dicaproin, obtained in the same way in 6 g. yield from 5 g. (*b*), 25 cc. caproic acid and 15 cc. H_2SO_4 , sapon. no. 359.2, $[\alpha]_D^{18}$ -0.30° in substance, -0.46° in Et_2O , -0.25° in CCl_4 , -0.44° in petr. ether, 0.57° in $CHCl_3$. *l*- α -Lauro- β , γ -dibutyryn, sapon. no. 372.8, α -0.15° in a 1 dcm. tube, is obtained in 0.8 g. yield from 1 g. *l*-dibutyryn (α -1.05°) and 1.1 g. lauryl chloride heated 0.5 hr. on the H_2O bath, allowed to stand over moist KOH, extd. with Et_2O , washed with H_2O , treated with an equal vol. of alc., neutralized with alc. KOH, evapd. *in vacuo*, extd. with Et_2O , boiled with charcoal and dried with Na_2SO_4 . *l*- α -Stearo- β , γ -dibutyryn, m. 15°, inactive. *l*- α -Oleo- β , γ -dibutyryn, sapon. no. 351.9, α -0.07° in a 1 dcm. tube. In crystg. aminodibromopropaned-tartrate *d*-epihydrin alc. with at most α -4.02° in a 1 dcm. tube was obtained from the mother liquors. With *l*-tartaric acid, the *l*-aminodibromopropane, α -0.15° in Et_2O was obtained from the *dl*-compd. after several crystns. *l*-Aminoglycerol (*c*) is best obtained by inversion of *d*-epibromohydrin (*d*) into the *l*-series; 55 g. (*d*), α 37.25°, is slowly poured into 500 cc. of 15% HCl below 20°, then shaken 1 hr. with 100 cc. concd. HCl, extd. with Et_2O , washed with soda, dried with Na_2SO_4 and fractionated *in vacuo*; this gives 62 g. *d*- α -bromo- γ -chloropropan-2-ol, $b_{D,18}$ 88°, d. 1.7069, $[\alpha]_D^{18}$ 0.64°; 62 g. of this are shaken with 30 g. KOH in 60 cc. cold H_2O and extd. with Et_2O , giving 23 g. *l*-epichlorohydrin, d. 1.2007, $[\alpha]_D^{18}$ -25.61°, best distd. under 360° (b. 92-3°) to 260 mm. (b. 80-90°). This gives a *d*-formyl- α -chlorohydrin with α 4.10°, hydrolyzed by 15% HCl to a *l*-chlorohydrin, $[\alpha]_D^{18}$ -1.88° in H_2O , 25 g. of which yields 8 g. of a *d*-epihydrin alc. with d. 1.1054, $[\alpha]_D^{18}$ 7.69°; 1.5 g. of this with 2 g. $PrCO_2H$ gives 1.1 g. of a *l*-monobutyryn, sapon. no. 347.9, $[\alpha]_D^{18}$ -0.84° in alc., while 6.5 g. of the alc. yields 6 g. (*c*), $[\alpha]_D^{18}$ -14.08° in dil. HCl. *d*-Dibutyryn, sapon. no. 495.8, d. 1.0890, $[\alpha]_D^{18}$ 1.01°.

CHAS. A. ROULLIER.

Alkylation of pyrroles. III. K. HESS, F. WISSING AND A. SUCHIER. Univ. Freiburg i/Br. *Ber.* 48, 1865-84 (1915); cf. C. A. 8, 2706; Plancher and Tanzi, C. A. 9, 1477.—By the following modifications of the methods described in the literature, the yields of 2,3,5-trimethylpyrrole (*a*) has been materially increased. 2,3,5,4- $C_4HN-Me_3CO_2Et$ (Knorr and Hess, C. A. 6, 92) is obtained in 78.5 g. yield from 75 g. HON:

CMeAc + AcCH₂CO₂Et in 450 cc. AcOH at 90-5° treated in the course of 2 hrs. with 225 g. Zn dust, the Zn being boiled up 3 times with 100-cc. portions of AcOH after being filtered; 40 g. of the ester in 10 g. ice and 40 cc. concd. H₂SO₄ are shaken with 20 cc. of 20% H₂SO₄, heated 1.5 hrs. on the H₂O bath, cooled to -10°, treated with somewhat more than the calcd. amt. of cold 33% NaOH at such a rate that the temp. rises to 30° (about 15 min. required for the operation), distd. with steam, salted out, extd. with Et₂O and distd. *in vacuo*; this gives 17.8 g. (a). 200 g. of this are converted into the MgBr compd., treated with the equiv. amt. of EtBr, dild. to about 1 l. with Et₂O, boiled 50 hrs. (carefully protected from moisture), decompd. with ice H₂O, treated with excess of NaOH, the aq. and Et₂O layers distd. with steam, the distillate salted out, repeatedly extd. with Et₂O and the Et₂O soln., after coupling with diazobenzenesulfonic acid, is worked up as described in the earlier paper. There is thus obtained 150 g. of a product b₁₁ 52-103°, giving a strong pine-splinter reaction and divided by repeated distn. into 3 fractions: (1) 40 g., b₂₁ 53-4°, gives no pine-splinter reaction; (2) 10 g., gives no pine-splinter reaction after boiling 12 hrs. with 30 cc. concd. HCl and then b₂₁ 85-6°; (3) 20 g., b₂₁ 114-5°, gives a strong pine-splinter reaction. If it is desired to obtain only the chief product (1), the crude oil is best boiled with concd. HCl to destroy the pyrrole derivs. (1) is 2,3,5-trimethyl-3-ethylpyrrolenine (b), M₂-Et-C.CH: CMe.N: CMe, b₇₁₂ 158-9°, b₇₁₂ 155-6°, has a very characteristic C₈H₁₁N-menthol-

like odor, is extraordinarily volatile and is apparently not identical with Ciamician and Anderlini's product b. about 160° (*Ber.* 21, 2858 (1888)); on long standing in the air it becomes slightly yellowish; 0.2207 g. dissolves in 5.3 cc. H₂O at 25° and partially seps. on warming; a cold satd. aq. soln. gives with dil. I-KI a yellowish green oil, with KI-HgI₂ a thick, white amorphous ppt., with CdI₂ an amorphous ppt. like freshly pptd. AgCl, with alc. picric acid a cryst. *picrate*, C₁₈H₁₈O₇N₄, changes color 72°, decomp. 188-90°. *Chloromercurate*, (C₉H₁₁N.HgCl₂)₂.HCl, needles, changes color 120°, m. 122°, obtained from 0.5 g. base in 15 cc. H₂O acidified with HCl and treated with 15-6 cc. of 7% HgCl₂; by changing the concn. of the reacting substances, another Hg salt, m. 78°, is obtained. *Chloroplatinate*, m. 195°, decomp. immediately thereafter. *Chloroaurate*, softens 57°, m. 65-6°, decomp. on recrystn. Oxidation of the base with alk. KMnO₄ gives (CO₂H)₂. It is practically unchanged by N₂O₂ in alc. Fraction (2) above is a compound, C₁₈H₁₇N (described as C₈H₁₂N in the earlier paper), purified through the *picrate*, C₁₈H₁₈O₇N₄, spears of microscopic elongated prisms from alc., sinters 130°, m. 140-1°. Fraction (3) is 2,3,5-trimethyl-1-ethylpyrrole, resinifies to a dark sirupy mass with extreme ease in the air, being obtained colorless only on distn. *in vacuo* in H, cannot be made to cryst., gives no dye with PhN₂Cl or diazobenzenesulfonic acid, forms a white cryst. ppt. with HgCl₂, yields no *picrate*, is but slightly sol. in H₂O, with faint alk. reaction to litmus, easily volatile with steam. 2,3,3,4-C₄H₉NMe-EtCO₂Et (Vecchi, *C. A.* 8, 3019) is obtained in 77 g. yield from 63 g. HON: CMeCOEt, 85 g. AcCH₂CO₂Et and 400 cc. AcOH at 100° treated with 200 g. Zn dust in the course of 45 min., heated 1 hr. on the H₂O bath and the Zn dust extd. 6-8 times with 200-cc. portions of hot AcOH; 50 g. of this, on decarboxylation with H₂SO₄, yields 24.5 g. 2,5-dimethyl-3-ethylpyrrole, b₂₁ 112°, b₂₁ 121°, quickly turns brown in the air, hardly sol. in H₂O, with faint alk. reaction to litmus, yields in cold Et₂O an amorphous, flocculent, yellow-red *picrate*, with excess of HgCl₂ a flocculent ppt., with Me₃NC₆H₄CHO a crimson color. When the Me₃EtC₄HNMgI from 36 g. of this compd., 7 g. Mg and 46 g. MeI in 120 cc. Et₂O is treated with 41 g. MeI in 50 cc. Et₂O, heated 48 hrs. at 40°, decompd. with ice, extd. with Et₂O, the Et₂O evapd., the oily residue added to the aq. layer, the mixt. acidified with concd. HCl, boiled to disappearance of the pyrrole reaction, made strongly alk. with NaOH, steam distd., salted out, extd. with Et₂O and distd. *in vacuo* obtained 5.1 g. b₂₁ 80-95°, and 5.8 g. b₂₁

95-100°. From the 1st two fractions by repeated distn. was obtained a compd. identical with (b), while the 3rd fraction yielded phyllopyrrole; this shows that the Et group in (b) is in the 3-position. In prep. 2,4,5,3-C₄HNMe₃EtCO₂Et by K. and H.'s method, the yield was increased to 76% by very slowly adding the Zn dust and keeping the temp. at 100-10° and this with 40% H₂SO₄ on the H₂O bath gave 55% of the 2,4,5-C₄H₂NMe₃Et; two 28 g. portions of this, each treated with the Grignard reagent from 5.5 g. Mg, 26 g. EtBr and 200 cc. Et₂O, then boiled 48 hrs. with 25 g. EtBr and worked up as above, gave 37 g. crude oil yielding 9 g. b₇₃₅ 70-3°, b₇₃₅ 173°, of a compound C₁₆H₁₇N, which by analogy with (b) is assigned the structure MeEtC.CH:CEt.N:CMe; 0.100 g. dissolves in 10.0 cc. H₂O at 22° and partly seps.

on warming. *Picrate*, bright yellow ppt. from alc., changes color 160°, contracts 170°, m. 190°, decomp. above 200°. *Chloromercurate*, C₁₆H₁₇N.2HgCl₂, needles from H₂O, m. 115°. *Chloroplatinate*, orange cryst. ppt. from H₂O, m. 169° (decompn.). *Chloroaurate*, yellow oil from H₂O, soon becoming coarsely cryst., m. 97-8°; from alc. it seps. in long table-like prisms with 0.5 mol. solvent, m. 215° (decompn.). Doubt having been cast by Oddo and Mameli (C. A. 9, 788) on the assumption by H. and W. that the C₄H₂NEt obtained by them is identical with Ciamician and Zanetti's (Ber. 22, 660(1889)) and Dennstedt's (Ber. 23, 2563(1890)), H. and W. have converted their compd. into the Ac and cinnamyl derivs. and proved its identity with D.'s compd.

CHAS. A. ROUILLER.

Characterization of halopyrroles. II. K. HESS AND F. WISSING. Ber. 48, 1884-6(1915); cf. C. A. 8, 2706.—To a mixt. of 8 g. Mg, 36 g. EtBr and 22 g. pyrrole in 250 cc. Et₂O at -17° is slowly added 27 g. Br in 250 cc. cold Et₂O, the temp. rising to -14°; the product is at once decompd. with ice H₂O, freed from Et₂O on the H₂O bath and distd. *in vacuo* at 50-60°; with the H₂O there distils an oil sepg. on the cold walls of the receiver in C₁₀H₈-like crystals which, drained off, spread on clay and placed in a vacuum desiccator over P₂O₅, decompd. in about 5 min. with a light explosion, deposition of C and evolution of HBr. The white compd., still moist, when brought near a Bunsen flame, deflagrates explosively with formation of HBr, C and NH₄Br. Although it could not be obtained in a state suitable for analysis, H. and W. have no doubt it is *bromopyrrole*. If the reaction mixt., after decompn. with H₂O and removal of the Et₂O, is distd. under atm. pressure, decompn. takes place and there distils over with the steam a *bromodipyrrole*, C₈H₇N₂Br, a bright refractive oil, smelling strongly of CHCl₃; quite unstable. Addition of I to a pyrrolemagnesium soln. at once produces a deep-seated decompn. and no definite product can be isolated. C. A. ROUILLER.

A new oxidation method. II. Action of aldehydes on hydramines of the pyrrolidine and piperidine series. K. HESS, F. MERCK AND CL. UBRIG. Univ. Freiburg i/B. Ber. 48, 1886-906(1915); cf. C. A. 8, 934.—The conversion of *sec*-hydramines of the pyrrolidine series, NH.CH₂.CH₂.CH₂.CHCHROH, into tertiary aminoketones,

MeN.CH₂.CH₂.CH₂.CHCOR, by HCHO has been extended to hydramines with primary alc. groups and to aldehydes other than HCHO. The 1st product is doubtless an aldehyde-ammonia addition product, HOCH₂N.CH₂.CH₂.CH₂.CHCHROH; at a

higher temp. the CHOH group is oxidized and the >NCHOH—simultaneously reduced to >NCH₂—. 1-[α-Pyrrol]-2-ethanol, b_{0.735} 95-9°, b_{0.735} 104-6°, b₁₅ 138-42° (appreciable decompn.), is obtained in 6.2 g. yield when 75 cc. of an Et₂O soln. of 12 g. Mg and 60 g. EtBr is treated with 33 g. pyrrole in 20 cc. cold Et₂O, then with 50 cc. C₆H₆, freed from most of the Et₂O *in vacuo*, heated to 40-50°, slowly treated with 22 g. ethylene oxide in 50 cc. C₆H₆ (the reaction being so regulated that the soln. is kept

gently boiling), heated 2-3 hrs. at 100-10°, the C_6H_6 layer decanted off, the suspension of basic Mg salts repeatedly shaken with Et_2O , faintly acidified with dil. H_2SO_4 , again extd. 2-3 times with 30-cc. portions of Et_2O , the C_6H_6 - Et_2O exts. shaken with 50 cc. H_2O , dried with potash, evapd. *in vacuo*, taken up in 30 cc. Et_2O , freed from tar by addition of gasoline (b. 45°) until no more dark particles sep., and distd. in a high vacuum in H; it is very difficultly volatile with steam; its aq. soln. is neutral to litmus; in the air it gradually turns brown and after a time deposits a solid resinous mass; it has a characteristic pyrrole odor. When 2.89 g. in 10 cc. $AcOH$ are shaken in H with 1.0-1.5 g. Pt sponge, 4 atoms H are absorbed in 18-20 hrs.; at the same time there is some esterification. Accordingly, after filtering the Pt and washing to neutral reaction, the filtrate is treated with 20 cc. HCl , concd. on the H_2O bath to a thick syrup to sapon. the ester and resinify any unattacked pyrrole, taken up in 30 cc. concd. HCl , allowed to stand with 3 g. Sn foil until the latter is dissolved, dild. with 400 cc. H_2O , freed from Sn with H_2S (which also brings down the pyrrole resin), concd., supersatd. with alkali and repeatedly extd. with $CHCl_3$; there is thus obtained 1.5-2.1 g. 1-[α -pyrrolidyl]-2-ethanol, b_{100} 78-80°, strongly refractive viscous oil of a disagreeable sperm-like odor, eagerly absorbs CO_2 from the air; 1.4 g. in 6 cc. H_2O , acidified with HCl , heated 4 hrs. at 115-20° with 2 cc. of 40% $HCHO$, gives the compound $MeN.CH_2.CH_2.CH_2.CH-$

CH_2CHO , mobile refractive oil of a narcotic but unpleasantly penetrating odor, b_{11-1} 79-80°, sol. in cold H_2O and partially sepg. on warming, reduces cold NH_3 - $AgNO_3$, yields a *picrate*, indistinct crystals from alc., sinters 177°, m. 181°. If 1 g. of the alc. in 5 cc. H_2O (without HCl) is heated 3 hrs. at 110-24° with 1 cc. of 40% $HCHO$, the product is the tertiary *hydramine* base, $MeN.CH_2.CH_2.CH_2.CHCH_2CH_2OH$, b_{14} 110-2°,

viscous oil of fainter odor than the secondary base; yield 0.5 g. When 13 g. α,α' -picolyethanol in 50 cc. hot alc. are slowly poured upon 41 g. Na, then treated with 450 cc. alc. in small portions, heated 45 min. at 130-40°, treated with 210 g. cold concd. HCl , filtered from the $NaCl$, concd. *in vacuo*, taken up in 30 cc. of 40% $NaOH$, shaken 2-3 times with 20 cc. $CHCl_3$, dried with potash, evapd. *in vacuo* at room temp. and rubbed with Et_2O in ice- $NaCl$, the syrup partially solidifies, yielding 5 g. of the α -form of 1-[α,α' -picolidyl]-2-ethanol, polygonal tables from Et_2O , having a fatty luster when dry, m. 99°, b_{21} 112-20°. The mother liquors on fractionation yield 2 g. of a liquid β -form, b_{21} 115-7°, viscous basic oil, together with by-products, b_{17} 65-98°, from which was isolated α -methyl- α' -ethylpiperidine. The above α -form and $HCHO$ in HCl at 137-40° quant. give the compound $MeN.CHMe.CH_2.CH_2.CH_2.CHCH_2CHO(a)$,

b_{11} 84-5.5°, strongly basic oil of narcotic odor, produces violent headaches when inhaled, becomes yellowish on long standing in corked tubes, sol. in H_2O in all proportions and partially sepd. from not too dil. solns. on warming, easily volatile with steam, reduces NH_3 - $AgNO_3$ on gentle warming, Fehling soln. almost not at all on boiling, yields an oily *phenylhydrazone* solidifying to needles; *picrate*, prisms and tables from alc., m. 178°; with NH_3OH the aldehyde regenerates the *sec*-hydramine base; at the same time $HCHO$ is formed. In the same way, 2.5 g. of the β -form of the hydramine with $HCHO$ gives 1.3 g. of an isomeric aldehyde, $C_9H_{17}ON$, b_{21} 85-7°; *picrate*, m. turbid 135°, clear 145-6°. From 10 g. 1-[α -piperidyl]-2-ethanol heated 4 hrs. at 120-5° with somewhat more than the calcd. amt. of $HCHO$ in faintly acid soln. is obtained 9.5-10 g. of 1-[α -N-methylpiperidyl]-2-ethanol, mobile oil, b_{10} 82-4°, does not become colored on standing, sol. in cold H_2O , partially seps. on warming, has the typical narcotic, alkaloidal odor of hygrine and related compds., reduces NH_3 - $AgNO_3$ on gentle warming but Fehling soln. only faintly on boiling. *Picrate*, prisms from alc., sinters 150°, m. turbid 154°, clear 158°. From 5 g. of 1-[α -pyrrolidyl]-1-ethanol and $HCHO$

is obtained 4.7 g. of the *ketone*, $C_7H_{15}ON$, mobile volatile oil, b_m 56–7°; *picrate*, sinters 172°, m. 174–5°. In the same way, 2 g. of the hydramine in 4 g. H_2O and 1 g. concd. HCl, heated 3 hrs. at 100–5° with 1.4 g. AcH, gives 0.6 g. of the *ketone* $EtN.CH_2.CH_2.CH_2.CHAc$, b_{17} 68–70°, while 2.6 g. of the hydramine, 12 cc. alc., 2.6

g. concd. HCl and 2.5 g. BzH heated 4 hrs. at 120° yields 2.1 g. of the *benzyl compound* $C_{15}H_{17}ON$, b_m 139–41°; *picrate*, sinters 160°, m. turbid 163°, clear 166°. From 100 g. butyrylpyrrole (obtained in 123 g. yield from C_4H_9NMgBr (from 125 g. pyrrole) and $PrCOCl$ by Oddo's method), reduced with 285 g. Na and 2 l. alc., is obtained 22–4 g. of 1-[α -pyrrolidyl]-1-butanol, b_{14} 67–9°, b_{15} 102–4°, seps. from petr. ether (b. below 50°) in needles, m. about 60°; 6 g. in 12 cc. H_2O and concd. HCl, heated 4 hrs. at 125–30° with 4.8 g. of 40% HCHO, gives the *ketone* $C_9H_{17}ON$ (b), b_{11} 83–5° (b_{12} 83–5° is also given), partially sol. in cold, almost wholly insol. in warm H_2O , easily volatile with steam, reduces warm $NH_3 \cdot AgNO_3$; when it is boiled with dil. HCl there distils over a N-free substance, neutral to litmus, of aromatic and aldehyde odor, swimming on the H_2O in oily drops. The distillate reduces warm $NH_3 \cdot AgNO_3$. The ketone with NH_2OH regenerates the original butanol. *Picrate*, prismatic rodlets from alc., m. turbid 103°, clear 110°. Na and alc. do not attack the ketone; Na-Hg in H_2O , kept neutral to faintly acid with HCl, partially reduces it to the tertiary hydramine. 1-[α -Piperidyl]-2-propanol, b_{11} 136–40°, is obtained in 7.2 g. yield from 20.8 g. of the *pyridyl compound*, b_{11} 112–5° (obtained in 3–5% yield from picoline and AcH), or practically quant. from the pyridyl compd. with H and Pt sponge in AcOH in 15 hrs.; 7.2 g., heated 4 hrs. at 115–28° with 5 g. of 40% HCHO, 5 cc. HCl and 3 cc. H_2O , gives 3.5 g. of the *ketone* $C_9H_{17}ON$, b_{11} 82–4° (slight decompn.), b_{12} 210° (only slightly increased decompn.), does not become colored even on long standing in corked tubes. *Chloroaurate*, prismatic columns from alc.-petr. ether, slowly sinters 100°, m. turbid 115–6°, clear 139°. *Picrate*, bright yellow prismatic needles from alc., sinters 148°, softens 155°, m. turbid 160–1°. The ketone is apparently identical with Piccinini's isomethylpelletierine (*Rend. accad. Lincei*, 8, II, 176(1899)), but the latter has not been described with sufficient exactness to make this certain. That aldehyde-ammonias undergo intermol. oxidations, like the intramol. oxidation assumed for the hypothetical intermediate product in the above reactions, is indicated by the Plöchl-Leuckhart reaction, whereby aldehydes and ketones heated with HCO_2NH_4 yield primary, secondary and tertiary amine bases. In the alkylation of NH_3 by HCHO, the reaction is assumed to be as follows: $>NH + HCHO \rightarrow >NCH_2OH \rightarrow >NMe + HCO_2H$, the HCO_2H yielding the 2nd Me group: $>NMe + HCHO + HCO_2H \rightarrow >NMeCH_2OH + HCO_2H \rightarrow >NMe_2 + CO_2$, etc., HCO_2H is more easily oxidized to CO_2 than $-CHOH-$ to $-CO-$ in the above intramol. oxidations, for 2.6 g. 1-[α -pyrrolidyl]-1-propanol in 6 cc. H_2O , heated 4–5 hrs. at 110–5° with 1 g. HCO_2H and 1.8 g. of 40% HCHO, gives 1.3–1.5 g. of the *hydramine base*, $MeN.CH_2.CH_2.CH_2.CHCH(OH)Et$, b_{14-5} 83°, less sol. in warm than in cold H_2O .

Picrate, long needles of microscopic rectangular prisms and rhombs, sinters 150°, m. 153–4°. In contrast with the ease with which the group $-HOCH.N<$ loses O, it was found that the group $>NCH_2-$ easily takes up O with formation of aldehyde and a lower alkylated amine: $>NCH_2- + O \rightarrow >NCH(OH)- \rightarrow >NH + -CHO$. Thus, when, according to Luboldt (*Arch. Pharm.* 236, 22 (1898)), scopoline is demethylated by treatment with the amt. of $KMnO_4$ calcd. for oxidation to CO_2 , HCHO is formed; the yield of demethylated product, norscopoline, is minimal, whereas if NH_2OH is used the yield is almost quant.: the reaction may therefore be written $C_{17}H_{19}(NMe)_2 + O \rightarrow C_{17}H_{19}(NCH_2OH)_2 \rightarrow C_{17}H_{19}N +$ reaction of NH_2OH on (a) and (b) shows that the oxidation

of the hydramine bases to the aminoketones and -aldehydes may also be reversed; it is believed that the mechanism of this reaction may be represented thus: ($R = -N.CH_2.CH_2.CH_2.CH-$) for (b): $MeRCOPr + H_2O \rightleftharpoons MeRC(OH)_2Pr \rightleftharpoons$

$HOCH_2RCH(OH)Pr \rightleftharpoons HRCH(OH)Pr + HCHO$. III. Action of aldehydes on primary hydramines. K. HESS AND CL. UBRIG. *Ibid* 1974-85.—At low temps., NH_3 alcs. with primary NH_2 groups react with aldehydes with loss of H_2O in the sense of Schiff bases, the reaction being reversible; e. g., $Me_2C(NH_2)CH_2CH(OH)Me(a) + HCHO \rightleftharpoons Me_2C(NHCH_2OH)CH_2CH(OH)Me(b) \rightleftharpoons Me_2C(N:CH_2)CH_2CH(OH)Me(c) + H_2O$. At higher temps., however, this condensation reaction is almost completely suppressed in favor of 2 competing reactions: (b) + $HCHO \rightarrow Me_2C(NHMe)CH_2CH(OH)Me(d) + HCO_2H$, and (d) + $HCHO \rightarrow Me_2C(NMeCH_2OH)CH_2CH(OH)Me(e) \rightarrow Me_2C(NMeCH_2)CH_2Ac(f)$. Since this reaction leads to the formation of the methylene deriv. (c) instead of a *sec*-amino ketone, it was attempted to prevent the formation of the group $-N:C<$ by substituting 1 of the H atoms of the NH_2 group with CO_2Et ; with $HCHO$ the resulting urethans gave the corresponding alkylated urethans in which the $CHOH$ group had been converted into the CO group: $Me_2C(NHCO_2Et)CH_2CH(OH)Me(g) + HCHO \rightarrow Me_2C[N(CH_2OH)CO_2Et]CH_2CH(OH)Me(h) \rightarrow Me_2C(NMeCO_2Et)CH_2Ac(i)$. Thus far, the CO_2Et group has not been removed from these compds. *Methylenediacetonealkamine*(c), $b_{11} 45-7^\circ$, $b_{710} 150-5^\circ$ (slight decompn.), was formerly (C. A. 8, 934) thought to be $Me_2C(NHMe)CH_2Ac$, but is decompd. with the greatest ease by boiling with H_2O into $HCHO$ and (a); it is obtained more easily than under the conditions formerly described, the yield being 1.3 g. from 2 g. (b) and 1.4 g. of 40% $HCHO$ in acid soln. heated 4.5 hrs. at 50° ; from 8 g. (a) and 6 g. $HCHO$ 4.5 hrs. at $115-20^\circ$ the yield is 7.5 g. *Picrate*, spears from 50% alc., sinters 130° , liquefies 138° , m. clear $138-9^\circ$. When two 6-g. portions of (a) are heated 4.5 hrs. at $142-5^\circ$ each with 13.4 g. $HCHO$ and 2 cc. H_2O , then dild. with 15 cc. H_2O and extd. with Et_2O there is obtained 7.8-8.5 g. oil, $b_{11} 42-73^\circ$, sepd. by distn. into 1 g. (c), *methylldiacetonealkamine*(d), $b_{11} 73-5^\circ$, and *dimethylldiacetoneamine* (f), $b_{11} 59-61^\circ$, mobile refractive oil of narcotic odor, whose *picrate* sinters $180-1^\circ$, m. 183° . From 8 g. (a) heated 4.5 hrs. at $115-20^\circ$ with 9.5 g. of acidified 40% AcH is obtained 7 g. of *ethylenediacetonealkamine*, $b_{11} 42-7^\circ$, quickly volatilizes in the air, quite volatile with Et_2O vapors, gives AcH with hot H_2O ; *picrate*, sinters about 147° , m. 152° . *Benzylidene compound*, in 9 g. yield from 10 g. (a) and 10 g. BzH in 40 cc. of 95% alc. acidified with concd. HCl and heated 7 hrs. at 90° , $b_{0.001} 94-5^\circ$, $b_{0.022} 87-8^\circ$, $b_{11} 139-40^\circ$ (slight decompn. even in a high vacuum), yellow oil of a faintly basic, not unpleasant odor; *picrate*, prismatic needles from alc., sinters 166° , m. $170-1^\circ$; *hydrochloride*, from the base and concd. HCl , somewhat hygroscopic, m. 199° . With $H_2NCONHNH_2.HCl$ and $KOAc$ in H_2O the base in a few sec. gives $PhCH:NNHCONH_2$. It cannot be reduced to the $PhCH_2$ compd. by Na and alc. From 10 g. (a) in 9 g. soda and 25 cc. H_2O shaken with 9.3 g. $ClCO_2Et$ until the odor of the latter disappears is obtained 11.5 g. of the *urethan* (g), thick oil, $b_{11} 142^\circ$; 5.2 g. of this in 11 g. of 40% $HCHO$ and 2 cc. H_2O heated 12 hrs. at $145-50^\circ$ in a shaking bath gives 3 g. of the *base* (i), $b_{11} 123-5^\circ$, gives $HCH:NNHCONH_2$ with semicarbazide; in its prepn. HCl must be excluded, otherwise much resinification occurs. Alc. impedes the reaction, 1.4 g. unchanged (g) being recovered after heating 2 g. of it with 1.2 g. of aq. 40% $HCHO$ and 4 cc. alc. 4 hrs. at $173-5^\circ$; if the temp. is kept at $203-8^\circ$ for 4 hrs., however, the reaction takes a different course and there is obtained about 1 g. of the *methylene compound* $C_{11}H_{18}O_2N_2$, b_{11} about $165-70^\circ$, seps. from C_6H_6 -petr. ether in triclinic crystals, m. 132° . The *urethan* $PrO_2CNHCH_2CH_2OH$, from $NH_2CH_2CH_2OH$ and $ClCO_2Pr$, $b_{11} 150-1^\circ$; 9.2 g. heated 7 hrs. at 145° with 6.1 g. of 40% $HCHO$ and 5 cc. H_2O yields, together with 3.5 g. unchanged alc., 3.5 g. of the *compound* $PrO_2CNMeCH_2CHO$, b_{11}

103-5°, refractive mobile oil of pleasant, ester-like, basic odor, reduces warm NH_4AgNO_3 , yields an oil phenylhydrazone which soon crystals. *1-Phenylethan-1-ol-2-amine*, $m. 30-5^\circ$, $b_{710} 160^\circ$, is obtained in 2-3 g. yield from 20 g. $\text{PhCH}(\text{OH})\text{CN}$ in 200 cc. of cold 50% alc. kept just acid with HCl while being treated with 750 g. of 5% Na-Hg in small portions; 2.6 g. in 5 g. soda and 10 cc. H_2O gives with 2.1 g. ClCO_2Et 3.6 g. of the *urethan*, pearly leaflets from 50% alc., $m. 86^\circ$; 3.6 g. of this heated 12 hrs. at 140-5° with 5.2 g. of 40% HCHO yields 2.1 g. of the compound $\text{BzCH}_2\text{NMeCO}_2\text{Et}$, $b_{16} 181-3^\circ$, thick oil of a faintly basic aromatic odor; its aq. soln. is neutral to litmus.

CHAS. A. ROUITLER.

Synthesis of *N-methylhexahydro- α,α' -lutidinedicarboxylic acid*. K. HESS AND F. WISSING. Univ. Freiburg i. Br. *Ber.* 48, 1907-12(1915).—From 10 g. lutidine, $b_{710} 142-4^\circ$, gently boiled with 60 g. KMnO_4 in 1500 cc. H_2O until colorless, filtered, and concd. on the H_2O bath to incipient sepn. of salt and treated with concd. HCl , is obtained 7.6 g. lutidinic acid (a), $m. 226^\circ$; 0.100 g. dissolves in 8 cc. of 60% AcOH at 40°; 8 g. in 500 cc. hot alc. poured upon 80 g. Na , heated with addition of more alc. if necessary until the Na is dissolved, cooled, treated with 370 g. concd. HCl , freed from alc., treated at 60-70° with 60 cc. of 20% NaNO_2 , and extd. with Et_2O in a Kempf extractor, gives 2.9 g. of *nitroso acid*, granular crystals from Et_2O , gives a strong Liebermann reaction, converted in concd. aq. soln. by HCl gas into 1.9 g. of a mixt. (probably *cis-trans* isomers) of *hexahydro- α,α' -lutidinic acid hydrochlorides* (b), decomps. about 290-5°, consisting of microscopic regular hexangular tables and prismatic needles. If, on the other hand, to 120 cc. of 10% aq. gum arabic, 100 cc. of 10% H_2PtCl_4 , 75 cc. of 1% colloidal Pt soln. and 305 cc. H_2O , satd. with H , is added 15 g. (a) suspended in 900 cc. AcOH and the mixt. hydrogenated under 3 atm. at 40°, the calcd. amt. of H is absorbed in 15 min.; on concg. the resulting soln. *in vacuo* at 50° to 200-300 cc., dialyzing through parchment (changing the dialyzate every 24 hrs.), concg. *in vacuo* and adding dil. HCl , only 1 form of (b) is obtained; yield, 17.5-18 g. from 18.5 g. (a); three 2.1-g. portions, each heated 4 hrs. at 135-40° with 4.5 g. of 40% HCHO and 8 cc. H_2O , concd. to incipient crystn. and supersatd. with concd. HCl , yield 5.5 g. of the *N-methyl acid hydrochloride* $\text{C}_8\text{H}_{14}\text{O}_4\text{NCl}$, polygonal tables from 90% alc., $m. 225-6^\circ$ (decompn.), hygroscopic in the air; converted by freshly pptd. Ag_2CO_3 in H_2O into the free acid, flat 4- and 6-sided tables with 1 mol. solvent from hot H_2O , $m. 225^\circ$ (incipient decompn.), *Copper salt*, $\text{C}_8\text{H}_{11}\text{O}_4\text{NCu}\cdot\text{H}_2\text{O}$, from the acid in 1% aq. soln. boiled 0.5 hr. with freshly pptd. CuO , thread-like azure needles, changes color about 235°. Alkylation of 8.5 g. piperidine by heating 4 hrs. at 110-5° with 10 g. of 40% HCHO (cf. Eschweiler, *Ber.* 38, 881(1905)) gave quant. about equal parts of methylpiperidine, $b_{710} 105-7^\circ$, and *methylenebis(piperidine)*, $b_{14} 103-4^\circ$. C. A. R.

A new transformation of acenaphthylene and synthesis of biacenaphthylidine, a new yellow hydrocarbon. J. DOLINSKI AND K. DZIEWONSKI. Acad. Sci., Cracow. *Ber.* 48, 1917-31(1915); cf. C. A. 9, 211.—When 50 g. acenaphthylene in 120 g. AcOH and 0.5 cc. HCl (d. 1.19) is heated 1-2 hrs. on the H_2O bath, there gradually seps. about 40 g. of a mixt. of polymerization products, *cryst. biacenaphthylidene* (a) and a yellow amorphous substance (b); it is powdered and extd. repeatedly, first with cold, then with hot C_6H_6 , (b) dissolving in the cold and (a) sepg. from the hot exts. in bright yellow leaves (yield, 20%). If it is not desired to isolate (b) but only to obtain (a) in good yield, it is better to treat 50 g. acenaphthylene in 500 cc. hot AcOH with 80 g. picric acid in AcOH and 5 cc. concd. HCl , heat 10 hrs. on the H_2O bath, filter the resulting *picrate* of (a) and *cryst.* it from xylene; it seps. in crimson needles with metallic luster, and is converted by NH_4OH into the free (a); yield, 37-40%. (a), after repeated crystn. from C_6H_6 or its higher boiling homologs, forms golden yellow leaves or tables, $m. 277^\circ$ (cor.), sol. in cold concd. H_2SO_4 with blue to greenish blue color; its solns.

show intense violet-blue fluorescence, most marked when very dil. (e. g., 0.00125%), quickly disappearing when the soln. is exposed to strong sunlight, the color at the same time changing from bright yellow to orange. On the other hand, in the dry state or in soln. in the dark, (a) is quite stable. Mol. wt. in boiling PhNO_2 , 297–306. From all its properties, D. and D. conclude (a) has the structure (I) or (II), or possibly both,

especially in soln. *Picrate*, $\text{C}_{24}\text{H}_{16.2}\text{C}_6\text{H}_5(\text{NO}_2)_3\text{OH}$, m. $216-7^\circ$. Heated to the b. p. in AcOH with excess of $\text{Na}_2\text{Cr}_2\text{O}_7$, (a) gives naphthalic anhydride almost quant. With HI (d. 1.5) and red P 8 hrs. at $180-5^\circ$, it gives 7,7-biacenaphthyl. When 2 g. (a) in 300 cc. boiling CS_2 is heated 1 hr. on the H_2O bath with 2.3 g. Br. in CS_2 and the resulting ppt. is washed with cold and then with hot C_6H_6 , there is obtained 80% of the 8,8-dibromo derivative (III), hair-like, orange-yellow needles, decompd. by long treatment

with boiling C_6H_6 , much more quickly in higher boiling solvents, gradually dissolving with dark red color, losing HBr and forming an exceeding easily sol., amorphous, red-brown compd.; in a capillary, (III) decomp. about 203° and dissolves easily in cold concd. H_2SO_4 with dark green, almost black color; with $\text{Na}_2\text{Cr}_2\text{O}_7$ in boiling AcOH it forms naphthalic anhydride almost quant. A by-product formed in small amt. in the prepn. of (III) is α, α' -dibromobiacenaphthylidene (IV), obtained in better yield by adding to 1.5 g. (a) in 1 l. CHCl_3 1.2 g. Br in CHCl_3 , allowing to stand 12 hrs., and extg. the resulting mixt. of (III) and (IV) with boiling C_6H_6 ; (IV) seps. from the C_6H_6 in hair-like yellow needles, easily sol. in org. solvents, m. 310° (decompn.), difficultly sol. in cold H_2SO_4 with bright green color, oxidized by $\text{Na}_2\text{Cr}_2\text{O}_7$ in AcOH to α -bromonaphthalic anhydride. From 2 g. finely divided (a) (prepd. by pptg. from 15 cc. hot PhNO_2 with 150 cc. alc.) suspended in 50 cc. AcOH and allowed to stand 12 hrs. in the dark with 10 cc. HNO_3 (d. 1.5) is obtained α, α' -dinitrobiacenaphthylidene, dark red needles from PhNO_2 , does not m. 360° , deflagrates on a Pt foil, oxidized by CrO_3 to α -nitronaphthalic anhydride. (b) is the chief product (70–80%) of the acid polymerization of acenaphthylene when the latter is treated directly in hot AcOH with concd. HCl; it forms no picrate and is purified by repeated pptn. from cold C_6H_6 with alc.; it is exceedingly sol. in cold CHCl_3 , C_6H_6 , PhNO_2 , Me_2CO , etc., difficultly in Et_2O , AcOH, alc. and ligroin, easily in H_2SO_4 with olive-green color, softens 180° , m. $185-90^\circ$, changes to dark or brown-yellow on long exposure to light, almost quant. oxidized to naphthalic anhydride by CrO_3 ; compn., $(\text{C}_{12}\text{H}_8)_n$; mol. wt. in boiling PhNO_2 , 755, in freezing CHBr_3 , 738–76. It is designated by D. and D. as an *allo-polyacenaphthylene*. C. A. R.

Additions to two earlier communications (oxonium bases with the character of alkalis, and the iodides of methylphenazonium). F. KEHLMANN. Univ. Lausanne. *Ber.* 48, 1931–3(1915).—The trimethylfluorescein bicarbonate described in C. A. 9, 324, has since been analyzed and the mol. ratio dimethoxyfluorane: CO_2 found to be 1:1, showing that the compd. is really a bicarbonate. The prediction in C. A. 8, 1283, that if the green periodide of methylphenazonium is semiquinoid, it should be possible to prep. it from the green semiquinoid iodide by addition of mol. I according to the equation $\text{C}_{12}\text{H}_{11}\text{N}_2\text{I} + \text{C}_{12}\text{H}_{11}\text{N}_2\text{I} + \text{I}_2 = \text{C}_{24}\text{H}_{22}\text{N}_4\text{I}_4$ has been verified; when mol. amts. of the semiquinoid iodide and I in just enough boiling alc. are cooled, fine, dark needles of the comp. $\text{C}_{24}\text{H}_{22}\text{N}_4\text{I}_4 \cdot \text{EtOH}$ quickly sep.; they are in all respects identical with the compd. previously described.

CHAS. A. ROULLER.

Constitution and color. IV. Color of the azo compounds and their salts. F. KHERMANN. Univ. Lausanne. *Ber.* 48, 1938-8(1915); cf. *C. A.* 8, 110.—As a result of the study of the azines it might be expected that the azo compds., since they are doubly unsatd. and each of the N atoms may independently become pentavalent by addition, would yield two series of salts with strong acids; this has been confirmed. PhN:NPh in ordinary concd. H_2SO_4 is intensely golden yellow, without a tinge of red even in thick layers, while in acid with 25% SO_3 it is deep red in thick and greenish yellow in thin layers, the latter color persisting only a few min. as sulfonation rapidly sets in and the color quickly becomes identical with that in ordinary concd. acid. If the golden yellow soln. is dild. in stages with H_2O , the color becomes lighter without change in tone and finally disappears, with sepn. of the free PhN:NPh , while the soln. of the SO_3H acid under the same conditions finally becomes of a very slightly intense bright orange-yellow, the sulfate being hydrolyzed and the faintly colored aq. soln. of the free SO_3H acid resulting. The solns. of $p\text{-H}_2\text{NC}_6\text{H}_4\text{N:NPh}$ (a) in acid of 25% SO_3 content and in ordinary concd. acid are the same optically as those of PhN:NPh ; on dildn. of the latter there appears at a certain stage a blue-red color fading out only on addition of much H_2O and depositing the free azo compd. The solns. of chrysoidine (b) in fuming and in 98% H_2SO_4 are both golden yellow; dildn. with a little H_2O produces the same blue-red color as with (a), while much H_2O gives an orange-yellow color and neutralization with NH_4OH gives the somewhat lighter color of the free base (b). These facts may be explained thus: the orange-yellow PhN:NPh with concd. acid forms, without a true deepening ("Vertiefung") of the color but with a strong increase in its intensity, a golden yellow monoacid salt; with fuming acid, the 2nd N atom also adds acid with distinct deepening of the color; on the entrance of a SO_3H group in 1 of the Ph nuclei, the N combined with this nucleus loses its additive power and the resulting salt has the structure $\text{HO}_3\text{SC}_6\text{H}_4\text{N:N(HX)Ph}$. The phenomena in the case of (a) point to the existence of 2 series of salts. Since the triacid red and diacid golden yellow salts are optically the same as the diacid red and monoacid golden yellow salts of PhN:NPh the auxochromic action of the NH_2 group seems to be masked. The triacid salt has the structure $\text{PhN(HX):N(HX)C}_6\text{H}_4\text{NH}_2\text{X}$, the diacid salt probably $\text{PhN(HX):NC}_6\text{H}_4\text{NH}_2\text{X}$ since the NH_2 group in the form of the sulfate acts like a SO_3H group in decreasing the additive tendency of the azo N directly combined with the nucleus to which it is attached, while in the monoacid salt the NH_2 group, being free, deepens the color and at the same time increases the additive power of the azo N combined with the nucleus to which it is attached, so that the salt has the structure $\text{PhN:N(HX)C}_6\text{H}_4\text{NH}_2$. Moreover, if in the formation of the monoacid salt from the intensely orange-yellow (a) it were the NH_2 group which adds the acid, the resulting salt should be of about the same color as PhN:NPh ; the deepening of the color which in fact occurs indicates that the salt formation takes place at the chromophore, i. e., the azo N. In the case of (b), it is apparently impossible to obtain a tetra-acid salt. The golden yellow tri-, the blue-red di- and the orange-yellow monoacid salts have the structures $2,4\text{-(NH}_2\text{X)}_2\text{C}_6\text{H}_3\text{N:N(HX)Ph}$, $2,4\text{-(NH}_2\text{X)(NH}_2\text{)C}_6\text{H}_3\text{N:N(HX)Ph}$ and $2,4\text{-(NH}_2\text{X)-}$ $(\text{NH}_2)\text{C}_6\text{H}_3\text{N:NPh}$.

CHAS. A. ROUILLER.

Behavior of amino acids towards neutral salts in aqueous solution. P. PFEIFFER, with J. WÜGLER AND FR. WITKA. Univ. Zurich. *Ber.* 48, 1938-43(1915); cf. *C. A.* 9, 2652.—To det. whether the neutral salt compds. of NH_2 acids described in the earlier papers exist only in the solid state or also in aq. soln. in equil. with their components and complex ions, the soly., rotation and mol. wt. of NH_2 acids in the presence of neutral salts were detd. All 3 methods indicate that a part of the acids combine in the solns. with the salts and their ions, so that in aq. albumin solns. containing salts, especially blood serum and related media, neutral salt compds. undoubtedly exist. In all

to the electrolytes, indicated by the pptn. of Hg from Nessler's reagent, the consumption of KMnO_4 and the pptn. of Hg_2Cl_2 from HgCl_2 ; these reducing products are not formed at the cathode for the H evolved corresponds exactly with the current as measured in the coulometer. As in the Kolbe electrolyses, increase in the concn. of the soln. has a favorable influence, indicated by the increase in the ratio $\text{CO}_2:\text{H}_2\text{SO}_4$. Although these quant. results point to a Kolbe electrolysis, the synthesized product cannot be isolated from the mixt. of different K salts. Accordingly, 35 10-cc. portions of 7.5 *N* $\text{NH}_4\text{O}_2\text{SCH}_2\text{CO}_2\text{NH}_4$ were electrolyzed with 2 amp.-hrs. at cooled Pt electrodes with a density of 2 amp./sq. cm., then acidified with H_2SO_4 , boiled as long as HCHO was evolved (many hrs.), concd., the crystals (a) sepg. (chiefly $(\text{NH}_4)_2\text{SO}_4$), boiled with excess of $\text{Ba}(\text{OH})_2$, treated with CO_2 and filtered; the filtrate on concn. deposited a small amt. of $\text{CH}_3(\text{SO}_3)_2\text{Ba} \cdot 2\text{H}_2\text{O}$. The mother liquor from (a) was likewise boiled with $\text{Ba}(\text{OH})_2$; the BaSO_4 carried down with it most of the Ba sulfoacetate, while the filtrate contained more of the latter salt, $(\text{CH}_3\text{SO}_3)_2\text{Ba}$ (4 g. of which was isolated), and an easily sol. mixt. of salts (of $\text{HO}_2\text{SCH}_2\text{OH}$ and $\text{HO}_2\text{SCH}_2\text{O}$?), and $\text{Ba}(\text{NO}_3)_2$ (from the oxidation of the NH_3). The acidified electrolyzed soln. evolves HCHO when boiled and H_2SO_4 is simultaneously formed; this is explained by the hydrolysis of the hypothetical $\text{HO}_2\text{SCH}_2\text{O}$. The evolution of CO during the electrolysis and of SO_2 on boiling the acidified soln. is explained thus: $\text{HO}_2\text{SCH}_2\text{O} + \text{O} = \text{CO}_2 + \text{H}_2\text{SO}_4$; $\text{HO}_2\text{SCO}_2\text{H} = \text{CO}_2 + \text{H}_2\text{SO}_4$. When the free $\text{HO}_2\text{SCH}_2\text{CO}_2\text{H}$ is oxidized at a cooled Pt anode in a clay cell and a Pb cathode, CO_2 and unused, partly ozonized O are evolved at the anode, and H_2SO_4 and some HSO_4 are formed in the soln.; the ratio $\text{CO}_2:\text{H}_2\text{SO}_4$ is not quite 2:1, but no by-products could be detected. The current yield increases with increasing concn. and is 48% in 3 *N* soln. From a 6 *N* soln. of $\text{KO}_2\text{SCH}_2\text{CH}_2\text{CO}_2\text{K}$ with 35 amp.-min. at an anode density of 2 amp./sq. cm. are obtained 0.6293 g. H_2SO_4 , 0.3868 g. CO_2 , 0.1358 g. C_2H_4 and 0.0040 g. CO . AcOH was detected qual. and on boiling the acidified soln. HCHO , SO_2 and H_2SO_4 were found. The same results were obtained with the NH_4 salt but no $(\text{CH}_3\text{CH}_2\text{SO}_3\text{H})_2$ could be detected. A soln. of the NH_4 salt containing the free acid, when electrolyzed, freed from sulfates with BaCl_2 , acidified and boiled, gave AcH and AcOH , together with a little HCHO ; Ba sulfoacetate was also isolated, but no evidence of the presence of $(\text{CH}_3\text{CH}_2\text{SO}_3\text{H})_2$ was obtained. A 6 *N* soln. of MeSO_3K , electrolyzed with 52.5 amp.-min. at an anode density of 2 amp./sq. cm., gave only CO_2 at the anode, and H_2SO_4 , with a little HSO_4 in the liquid; on boiling, HCHO was evolved. The ratio $\text{CO}_2:\text{H}_2\text{SO}_4$ was 1:0.669. Electrolysis of free $\text{CH}_3(\text{SO}_3\text{H})_2$ in 10 *N* or more dil soln., of the acid K salt in 2 *N* soln., or the NH_4 salt in the presence of NH_4OH gave only CO_2 and H_2SO_4 (in acid soln. some O_2 and HSO_4 were also formed). $\text{CH}_3(\text{SO}_3)_2\text{Ba} \cdot 2\text{H}_2\text{O}$, thus far always described as slender rhombic tables, seps. from acid solns. in long needles, a drop of 2 *N* HCl or NaOH added to the neutral soln. producing the exclusive formation of the needles or tables, resp. Assuming the momentary existence of the free radicals $\text{HO}_2\text{SCH}_2\text{—}$, the above products obtained in the electrolysis of $\text{HO}_2\text{SCH}_2\text{CO}_2\text{H}$ give the following picture of the mechanism of the reaction: Shortly after the electrolysis begins, the originally neutral soln. becomes alk., CO_2 being split off and remaining in soln. as bicarbonate; this furnishes the condition which is a prerequisite of the Hofer-Moest reaction. The first product is probably $\text{HO}_2\text{SCH}_2\text{—} + \text{OH}' + \oplus = \text{HO}_2\text{SCH}_2\text{OH}$, which on further oxidation yields $\text{HO}_2\text{SCH}_2\text{O}$ and then $\text{HO}_2\text{SCO}_2\text{H}$ and finally $\text{H}_2\text{SO}_4 + \text{CO}_2$. As more and more H_2SO_4 is formed, the alkalinity diminishes, to be sure, but sulfates are also formed in increasing amts. and these, as well as an alk. reaction, favor the H.-M. reaction, and moreover, the acidity of the soln. favors the formation of the simplest, final oxidation products; both of these factors impede the formation of the Kolbe electrolysis product. The formation of C_2H_4 and $\text{CH}_3(\text{SO}_3\text{H})_2$ may possibly be represented thus: $2\text{HO}_2\text{SCH}_2\text{—} = \text{CH}_2\text{—} + \text{CH}_2(\text{SO}_3\text{H})_2$; $2\text{CH}_2\text{—} = \text{C}_2\text{H}_4$.

CHAS. A. ROULLIER.

Action of the Grignard reagent on tertiary pyrroles. Answer to B. Oddo. K. HESS. Univ. Freiburg i. Br. *Ber.* 48, 1969-74(1915); cf. C. A. 8, 2706; Oddo, C. A. 9, 73.—O.'s statements have been confirmed insofar as the non-formation of C_2H_6 from *N*-methylpyrrole and the Grignard reagent is concerned, the formation of C_2H_6 (in Et_2O soln.) observed by H. having been due to the presence of traces of moisture and not, as believed by O., of unmethylated pyrrole, as chem. pure C_4H_8NMe , indifferent towards K, was always used. It has been found that unmethylated pyrrole reacts vigorously in Et_2O with $AcCl$, in the absence of a G. reagent, with formation of acetylpyrrole, so that the reactivity of $AcCl$ towards *N*- C_4H_8NMe shows nothing contrary to the reactions of C_4H_8N itself and permits of no conclusion as to its reactivity in the presence of the G. reagent. Another fact contrary to O.'s assertion that C_4H_8NMe does not react with an ethereal soln. is the non-formation of $MeEtCHOH$ in the presence of $AcCl$, and, furthermore, no C_2H_6 is evolved when an acid chloride is added to *N*- C_4H_8NMe and $EtMgBr$ in Et_2O , this occurring only on decompn. with H_2O . The fact that an acid chloride and a G. reagent do not react with each other in the presence of C_4H_8NMe shows beyond doubt that the C_4H_8NMe and G. reagent first react in some way, probably forming an addition product sol. in Et_2O , so stable that it is not attacked by the acid chloride. H. represents the reactions thus: $N-C_4H_8NMe + EtMgBr \rightarrow C_4H_8NMe::BrMgEt + RCOCl + H_2O \rightarrow N, \alpha-C_4H_8NMeCOR + MgBrCl + C_2H_6$, and $C_4H_8N + EtMgBr \rightarrow C_4H_8N::BrMgEt \rightarrow N-C_4H_8NMgBr + RCOCl \rightarrow \alpha-C_4H_8NCOR$. The latter scheme is further confirmed by the fact that an *N*-acetylpyrrole is never obtained; the assumption that an *N*-acyl compd. is first formed and rearranges into the C-deriv. is rendered improbable by the low reaction temp. (36°).

CHAS. A. ROUILLER.

Action of derivatives of the three-carbon series on pyrrole. II. Preliminary. KURT HESS AND HEINRICH FINK. Univ. Freiburg i. Br. *Ber.* 48, 1986-2005(1915); cf. C. A. 8, 127.—When epichlorohydrin (a) and K pyrrole (b) are brought together, the (b) apparently first adds to the ethylene oxide group and the resulting product then loses KCl : $CH_2(C_4H_8N)CH(OK)CH_2Cl \rightarrow CH_2(C_4H_8N)CH.CH_2O$ (c) + KCl .

This is indicated by the fact that monochlorohydrin and (b) give only propylene oxide, C_4H_8N and KCl , the (b) merely acting as an alkali; and furthermore in the prepn. of (c) a dimer (d), $CH_2(C_4H_8N)CH.CH_2O.CH(CH_2C_4H_8N).CH_2O$, is formed as a by-

product. The best conditions for the prepn. of 1-*N*-pyrrolpropane 2,3-oxide (c) are the following: 305 g. (a) in 400 cc. very dry Et_2O at 40° is slowly treated with vigorous stirring in the course of 3.5 hrs. with 250 g. finely powdered (b), kept just at a boil, with turbinating, for 5 hrs., shaken with 400 cc. H_2O , the aq. layer acidified with 20% H_2SO_4 (20-30 cc.), filtered from the slight amt. of tar, shaken twice with 50 cc. portions of Et_2O , the combined Et_2O solns. washed with H_2O until neutral, dried with potash and fractionated *in vacuo*; yield, 80-90 g. unchanged (a), 136-40 g. (c) and 22 g. (d). (c), b_{11} $93-4^\circ$, mobile oil slowly becoming yellow, has a decided mustard oil-like odor, gives no ppt. with picric acid. (d), b_{16} $195-200^\circ$, thick oil easily becoming somewhat yellow, difficultly sol. in cold or hot H_2O with neutral reaction to litmus, can be distd. under atm. pressure, gives a strong pine splinter test, quite stable towards concd. HCl , dissolving in the cold with yellow color and not darkening even on boiling, insol. in dil. HCl ; mol. wt. in freezing $C_{10}H_8$, 227-45. When 43 g. $(ClCH_2)_2CHOAc$ (e) are added with vigorous turbinating to a suspension of 52 g. freshly prepd. (b) in 100 cc. boiling abs. C_6H_6 , boiled with turbinating 4 hrs., freed from C_6H_6 *in vacuo*, extd. with Et_2O and fractionated, there are obtained 20-5 g. (c) and 7-9 g. (d), while the residue insol. in Et_2O , when dried, dissolved in just the necessary amt. of cold H_2O and acidified

with cold dil. H_2SO_4 , yields a *diacetylpyrrole*, b_{16-7} 105° , solidifies to rectangular prismatic tables sepp. from petr. ether in prisms, m. 55° , difficultly sol. in cold and hot H_2O with faintly acid reaction to litmus, easily sol. in alkalies and reprecipitated by acids, gives AcOH when boiled with acids, gives a deep dark red color with alc. FeCl_3 , yields a cryst. K salt. The (e) is probably first split into (a) and AcCl in the above reaction. Grignard reagents do not act on (c) as might have been expected from the reactions with ethylene and propylene oxides (cf. C. A. 10, 467); there is first formed an addition product which takes up H_2O and decomps., giving *1-N-pyrrolyl-2-hydroxy-3-bromopropane* (f), $\text{C}_4\text{H}_4\text{NCH}_2\text{CH}(\text{OH})\text{CH}_2\text{Br}$, which is formed only after acidifying with H_2SO_4 and therefore cannot be ascribed to the formation of free HBr . To the G. reagent from 2.4 g. Mg and 12 g. EtBr in 50 cc. Et_2O are slowly added 12.3 g. (c) in the course of 20–5 min., the mixt. warmed 1–2 hrs. at 60° , poured upon ice, the Et_2O poured off, the aq. emulsion of Mg salts repeatedly washed with Et_2O , the aq. soln. acidified, again extd. with Et_2O , the exts. dried with potash and distd.; there is thus obtained 15 g. of (f), b_{14-1} $137-9^\circ$ (slight decompn.). If, on the other hand, after prepg. the G. reagent in the least possible amt. of Et_2O and dilg. with 100 cc. C_6H_6 , the (c) in an equal vol. of C_6H_6 is added and the mixt. is boiled 9 hrs., there is also obtained 1.5–2.0 g. of a *pyrrole alcohol*, $\text{C}_4\text{H}_4\text{NCH}_2\text{CH}(\text{OH})\text{Pr}$, b_{14} $115-7^\circ$. When 68.1 g. (f) in 100 cc. Et_2O are slowly treated with the G. reagent from 8 g. Mg and 40 g. EtBr , there is a vigorous evolution of C_6H_6 ; the resulting alcoholate is treated with 25.2 g. AcCl in 30 cc. Et_2O , the clear soln. decanted from the pptd. Mg salt, washed with H_2O until neutral and dried with potash; it leaves on cautious evapn. the *ester* $\text{C}_4\text{H}_4\text{NCH}_2\text{CH}(\text{OAc})\text{CH}_2\text{Br}$, thick syrup of pleasant, faintly aromatic odor, becomes pink in the air and after a time completely resinifies, decomps. completely at 125° under 11 mm.; the product from 58 g. (f), heated 15 min. with 6.6 g. Na in dry MeOH, allowed to stand 12 hrs., concd. *in vacuo*, dild. with 150 cc. H_2O and extd. with Et_2O yields 31.4 g. oil free from halogen, consisting of several products, only 1 of which has thus far been isolated: *1-N-pyrrolyl-2-hydroxy-3-methoxypropane* (g), b_{12} 143° . The *p*-nitrobenzoate of (f), prepd. like the acetate, m. $79-80^\circ$; 1.7 g. dissolves in 20 cc. hot alc. and seps. in indistinctly cryst. form; from Et_2O on slow evapn. it seps. in quadratic cubes. From 40 g. (c) heated 15 hrs. in a shaking bath at 100° with 200 cc. H_2O in a N atm. is obtained 40.5 g. of the *glycol*, $\text{C}_4\text{H}_4\text{NCH}_2\text{CH}(\text{OH})\text{CH}_2\text{OH}$, thick oil, b_{16} $167-8^\circ$, has a bitter taste; placed in excess of cold H_2SO_4 and slowly allowed to warm up to room temp., it soon becomes a faint pink; after a time, when cautiously dild. with H_2O , made alk. with NaOH and distd. with steam, it gives (c) quant.; treated in MeOH with MeI and Ag_2O , it gives a mixt., b_{17} $110-23^\circ$, of (g) and the isomeric 2-Me ether (see below). *1-N-Pyrrolyl-2-hydroxy-3-chloropropane* (h), b_{11} $109-10^\circ$, b_{19-10} 122.5° , is obtained in 156 g. yield from 131 g. (c) in 20–30 g. portions in 100–25 cc. cold Et_2O slowly satd. with HCl gas; five 30-g. portions are each shaken 48 hrs. with 30 g. dry Ag_2O and 45 g. MeI (0.5 of the Ag_2O being added the first day and the other 0.5 in 2 portions the 2nd day), filtered, dried, treated with dry HCl gas in ice-salt to convert the (c) formed into the chlorohydrin (the current of HCl is stopped as soon as the odor of HCl becomes perceptible), quickly freed from excess of HCl with H_2O , then from most of the Et_2O by cautious distn., and distd. with steam (for the product from 80 g. (h), the distn. was continued 75 min. and 1.5 l. distillate collected, most of the Me ether being in the distillate); both distillate and residue are salted out and exhaustively extd. with the least possible amt. of Et_2O ; the ext. from the distillate is fractioned and the portion b_{12} above 107.5° is combined with the ext. of the residue and again methylated as above, the process being repeated as long as the fraction b_{12} above 107.5° makes it profitable; there is thus obtained 105–15 g. of *1-N-pyrrolyl-2-methoxy-3-chloropropane* (i) b_{20} $103.5-5.0^\circ$, mobile oil of flowery odor; there is also obtained 0.9 g. of *1,3-dichloro-2-methoxypropane* (j),

b_{10} 48–50° (see below). When 30 g. pyrrole, dried with potash and freshly distd., are slowly treated at 140° with 3.4 g. K, then, in a slow current of dry H, with 15 g. (i), kept 2.5 hrs. at 120–30°, dild. with 50 cc. H₂O, neutralized with *N* H₂SO₄ and extd. with Et₂O, there are obtained 14 g. unchanged pyrrole, 2–2.5 g. of a compound.

probably $\text{N} \cdot \text{CH} : \text{CH} : \text{CH} : \text{C} \cdot \text{CH}_2 \cdot \text{CH}(\text{OMe}) \cdot \text{CH}_3$ (k), b_{20} 73–4°, mobile oil of intense,

not unpleasant odor, and 2.8–3.5 g. of 1,3-di-*N*-pyrrol-2-methoxypropane, b_{20} 149.5–50.5°. From 5 g. (i) heated 4.5 hrs. at 130–5° with 12 cc. of 20% KOH in MeOH and 10 cc. MeOH are obtained 1–1.5 g. (k) and 1.3–1.6 g. of 1-*N*-pyrrol-2-methoxy-3-hydroxypropane, b_{20} 105–8°. *sym*-Dichloropropanehydrin methyl ether (j), mobile, refractive, very volatile liquid of refreshing odor, b_{20} 47.5°, b_{140} 159–9.5°, is obtained in 55.4 g. yield, together with 5–7 g. unchanged (ClCH₂)₂CHOH, when 50 g. of the latter and 85 g. MeI are treated with 45 g. Ag₂O in small portions during the course of about 1 day, allowed to stand overnight, filtered, washed with Et₂O, and the filtrate and washings just satd. with HCl. The ester, ClCH₂COCH₂OAc, b_{16} 112–4°, is obtained in 16–7 g. yield from 30 g. (ClCH₂)₂CO in the least possible amt. of AcOH boiled 20 min. with 30 g. KOAc in 100 cc. AcOH, neutralized with concd. soda below 5° and exhaustively extd. (12 hrs.) with Et₂O. From 59 g. (b) suspended in 60 cc. dry C₆H₆ treated in H at 90° with 40 g. (ClCH₂)₂CHOMe in the course of 1 hr. and heated 0.5–1.0 hr. longer with turbinating at 90°, there are obtained (i) and an isomer, b_{11} 104.5–6.0°, stable only in closed vessels, quickly darkens in the air, has a faint pyrrole odor,

CHAS. A. ROUILLER.

Phenylfumaric acid. G. KARL ALMSTRÖM. Univ. Upsala. *Ber.* 48, 2009–10 (1915).—Phenylmaleic anhydride (Alexander, *Ann.* 258, 76(1890)), boiled 6 hrs. with excess of 2 *N* NaOH, acidified, extd. with Et₂O, evapd. and crystd. from C₆H₆, gives phenylfumaric acid, felted needles, m. 128–9° (gentle gas evolution), easily sol. in H₂O with very bitter taste, quickly reduces KMnO₄, reddens litmus, is dibasic with phenolph. as indicator, seps. from H₂O in needles with 2 mols. solvent, m. 80–100°; the anhydrous acid decomps. on melting into H₂O and phenylmaleic anhydride. Barisch's observations (*J. prakt. Chem.* 20, 187(1879)) therefore do not apply to phenylfumaric acid.

CHAS. A. ROUILLER.

Constitution of the phenolaldehyde salts. II. H. PAULY. Würzburg. *Ber.* 48, 2010–8(1915); cf. *C. A.* 9, 2253; Hantzsch, *C. A.* 9, 1332.—Contrary to H.'s statement, the hemihydrate, as well as the anhydrous form, of the acid Na₂ salt of *o*-OHC-C₆H₄CO₂H, is pure white; the yellow color attributed to it by Ettling (*Ann.* 35, 241 (1840)) was due to traces of the neutral yellow salt. It was prepd. by treating 2.44 g. OHCC₆H₄CO₂H in 10 cc. of 60% alc. with 9.5 cc. of *N* NaOH and washing with Me₂CO and Et₂O. The anhydrous form was prepd. by H.'s method (*Ber.* 39, 3089 (1906)); the yellow color which it assumes in moist air can be washed out with Me₂CO and Et₂O. That this color is due to the neutral salt resulting from hydrolysis is shown by warming either form of the acid salt with H₂O; there at once sep. fine oily drops, a strong odor of OHCC₆H₄CO₂H is evolved and the soln. becomes yellow. The possibility of the existence of solid colored *m*-phenolaldehyde salts has been proved. Thus, 0.4 g. pure white isovanillin, prepd. free from traces of 3,4-(HO)₂C₆H₃CHO through its MeO₂C compd., and subsequent hydrolysis with aq. C₆H₅N, when treated in 10 cc. MeOH and 20 cc. Et₂O with an equiv. amt. of NaOMe in MeOH, then with 50 cc.

Et_2O and allowed to stand, yields the *sodium salt* in S-yellow needles. Again, 1.5 g. isovanillin in 8 cc. AcOH treated dropwise with 1.6 g. Br in 4 cc. AcOH give a *bromo-isovanillin*, dazzling white needles from alc., m. 208° , forming a colorless anil which gives a yellow melt, while with NaOMe in MeOH and subsequent addition of Et_2O it yields a strongly yellow cryst. *sodium salt* regenerating the colorless aldehyde with acids. Since even the most recent work seems to confirm the impossibility of the existence of *m*-quinoids, the above facts overthrow the last evidence in favor of the theory that the colored salt of phenolaldehydes are quinoid. The remainder of P.'s answer to H. contains no new exptl. material.

CHAS. A. ROUILLER.

Action of certain acid reagents on the substituted ureas and thiazole. II. F. B. DAINS, R. C. ROBERTS AND R. Q. BREWSTER. *J. Am. Chem. Soc.* 38, 131-40 (1916); cf. *Ibid.* 22, 181 (1900).—Benzodi-*o*-tolylamidine, $\text{PhC}:(\text{NC}_6\text{H}_4\text{Me})\text{NHC}_6\text{H}_4\text{Me}$, from mol. proportions of BzCl and $\text{CO}(\text{NHC}_6\text{H}_4\text{Me})_2$ heated 4 hrs. at 170° , needles from alc., m. $87-8^\circ$. Isovalerdiphenylamidine, from iso-AmCOCl and $\text{CO}(\text{NHPh})_2$ at 140° , m. 103° (possibly identical with the compd. obtained by Hofmann from iso-AmCO₂H, PhNH₂ and PCl_5 ; cf. *Jahresb.* 1865, 416); chloroplatinate, yellow, m. 207° ; picrate, m. $144-5^\circ$. Isovalerdi-*m*-tolylamidine, needles, m. 102° ; yellow chloroplatinate, m. 214° . *p*-Tolyl compound, m. $91-2^\circ$; hydrochloride, m. 175° ; chloroplatinate, m. 199° . *m*-Nitrobenzo-di-*p*-tolylamidine, yellow needles from alc., m. 137° . AcCl and $(\alpha\text{-C}_{10}\text{H}_7\text{-NH})_2\text{CS}$ at 90° give $\text{C}_{10}\text{H}_7\text{NCS}$ and $\text{C}_{10}\text{H}_7\text{NHOAc}$ and with BzCl at 160° are obtained the corresponding Ph compds., only traces of basic products being formed. Similarly, phthalyl chloride and $\text{CS}(\text{NHPh})_2$ at 160° yield chiefly PhNCS and phthalanil, with a small amt. of $(\text{PhNH})_2\text{C}:\text{NPh}$, while $\text{CO}(\text{NHPh})_2$ gives chiefly phthalanil, although the odor of PhNCO and COCl_2 are also noticeable; no amidine is formed. $\text{CS}(\text{NHPh})_2$ and Ph_2NCOCI at $110-20^\circ$ smoothly form PhNCS, $(\text{PhNH})_2\text{C}:\text{NPh}$, Ph_2NH and COS; similar results are obtained with di-*p*- and -*o*-tolylthioureas, and with $\text{CO}(\text{NHPh})_2$; cf. Dixon, *J. Chem. Soc.* 75, 405 (1899). From 2 mols. $\text{PhNHCSN}^+\text{EtPh}$, 2 mols. $\text{C}_6\text{H}_5\text{N}$ and 1 mol. COCl_2 in C_6H_6 are obtained $\text{C}_6\text{H}_5\text{N.HCl}$ and carbonylbis(diphenyl-ethylthiourea), $\text{CO}(\text{NPhCSN}^+\text{EtPh})_2$, needles from alc., m. 166° , not desulfurized by HgO in boiling C_6H_6 . Triphenylmethylurea, m. 105° , is obtained, together with PhNCS, from PhNHCONMePh and Ph_2NCOCI at 150° ; similar results are obtained with $\text{PhNHCONMePh} + \text{MePhNCOCI}$ and $\text{PhNHCON}^+\text{EtPh} + \text{Ph}_2\text{NCOCI}$. α,β -Diphenyl- α -methyl- β -ethylurea, from $\text{PhNHCON}^+\text{EtPh}$ and PhMeNCOCI at $150-60^\circ$ or from PhNH^+Et , PhMeCOCl and $\text{C}_6\text{H}_5\text{N}$ at 140° , m. 74° . $\text{PhN}:\text{C}(\text{NHPh})\text{SMe}$ heated 15 min. on the H_2O bath with a little more than 1 mol. Ac_2O yields acetylisothiodiphenylurea methyl ether, $\text{PhN}:\text{C}(\text{N}^+\text{AcPh})\text{SMe}$, cubes from dil. alc., m. 71° , only slightly sol. in dil. acids, forms no solid hydrochloride with HCl gas in C_6H_6 and no picrate; alkalis regenerate the original ether; it is also obtained from 2 mols. of the latter, allowed to stand in C_6H_6 with 1 mol. AcCl. *m*-Nitrobenzoylisothiodi-*o*-tolylurea ethyl ether, from $\text{MeC}_6\text{H}_4\text{N}:\text{C}(\text{NHC}_6\text{H}_4\text{Me})\text{SEt}$, $\text{O}_2\text{NC}_6\text{H}_4\text{COCl}$ and $\text{C}_6\text{H}_5\text{N}$, m. 122° , non-basic, decompd. by boiling alc. KOH into EtSH, $\text{CO}(\text{NHC}_6\text{H}_4\text{Me})_2$ and $\text{O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$. *m*-Nitrobenzoylisothiodiphenylurea methyl ether, m. 101° . All attempts similarly to replace the anilido H by the grouping R_2NCO at the temp. of boiling C_6H_6 failed, while at higher temps. an alkyl chloride, mustard oil and trisubstituted urea are formed. Thus, $\text{PhN}:\text{C}(\text{NHPh})\text{SMe}$ and Ph_2NCOCI heated 4 hrs. at 150° give MeCl, PhNCS and PhMeNCONHPh . *o*-Tolylmethylphenylurea, from $\text{MeC}_6\text{H}_4\text{N}:\text{C}(\text{NHC}_6\text{H}_4\text{Me})\text{SEt}$ and PhMeNCOCI at 150° , needles from gasoline, m. 117° , also obtained from *o*- $\text{H}_2\text{NC}_6\text{H}_4\text{Me}$ and PhMeNCOCI at 125° . α,α -Diphenyl- β -*o*-tolylurea, from $\text{MeC}_6\text{H}_4\text{N}:\text{C}(\text{NHC}_6\text{H}_4\text{Me})\text{SEt}$ and Ph_2NCOCI , m. 85° . By modifying the conditions it is possible to obtain from allylthioureas and acyl chlorides not only the thiazoles but also their acyl derivs. Thus, mol. proportions of $\text{C}_6\text{H}_5\text{NHCN}^+\text{HPh}$, $\text{C}_6\text{H}_5\text{N}$ and BzCl allowed to

stand in C_6H_6 yield α -allyl- β , β -benzoylphenylthiourea, m. 125° ; on concg. the C_6H_6 soln. with heat, it decomps. quant. into C_6H_5NCS and $BzNHPh$. With $AcCl$ instead of $BzCl$, only C_6H_5NCS and $AcNHPh$ were obtained, but $AcCl$ and p - $BrC_6H_4NHCSNHCH_3$ gave α -allyl- β -acetyl- β - p -bromophenylthiourea, m. 86° ; heated a few min. above its m. p., it decomps. into C_6H_5NCS and $AcNHC_6H_4Br$ while KOH hydrolyzes it to the original thiourea. *p*-Chloro compound, m. 84° . The rearrangement of $C_6H_5NHCSNHPh$ and $AcCl$ without a solvent into a thiazole deriv. can also be effected with $BzCl$ after 30 min. on the H_2O bath. *2-p*-Bromophenylamino-5-methyl-4,5-dihydrothiazole, from $BrC_6H_4NHCSNHCH_3$ and $AcCl$ heated 20 min., or from the thiourea and concd. HCl in a pressure bottle at 100° , m. 107° ; picrate, m. 156° . *p*-Chloro compound, m. 116° ; hydrochloride, m. 226° . *m*-Tolyl compound, m. 90° ; picrate, m. 158° . Just as in the isourea ethers, the anilido H in these thiazoles is very reactive towards Ac_2O . *2*-Phenylbenzoylamino-5-methyl-4,5-dihydrothiazole, from the $PhNH$ compd. and $BzCl$ in C_6H_5N , m. 118° , non-basic, hydrolyzed easily to the original thiazole by alc. KOH or cold HCl .

CHAS. A. ROUILLER.

Organic periodides. I. Periodides of phenacetine, methacetine and triphenine. W. O. EMERY. *J. Am. Chem. Soc.* 38, 140-50 (1916).—*Acetphenetidine hydriodide*, $(EtOC_6H_4NHAc)_2HI$, from phenacetine in alc.-free $AcOEt$ treated with HI gas freed from I and H_2O by passing over red P and P_2O_5 , needles, m. $147-8^\circ$. *Acetanisidine hydriodide*, m. $125-7^\circ$. In the case of triphenine no pure HI salt could be isolated; no ppt. was formed on passing HI into the base in $AcOEt$, $CHCl_3$ or C_6H_6 ; evapn. of the solns. spontaneously or by the aid of a blast and gentle heat left a cryst. residue of nearly colorless needles or prisms and periodide-like crystals, easily yielding a periodide on treatment with I in $AcOH$ or $EtCO_2H$. In perfectly dry air, these salts are reasonably stable but immediately yield their acid to H_2O or alc. Treatment of the above bases with I , KI and HCl , I and aq. or aq.-alc. HI of known strength, or of the HI salts with the required amt. of I yields the corresponding periodides. *Acetphenetidine hydriododide*, $(C_{10}H_{11}O_2N)_2HI.I_2$, is obtained only by the last of the above methods, the others yielding mixts. of the base and the tetraiodide; it seps. from $AcOH$ in ruby-red to reddish brown needles, softens $120-1^\circ$, m. $124-5^\circ$. *Tetraiodide*, $(C_{10}H_{11}O_2N)_2HI.I_4$, obtained by all of the above methods and from the diiodide with I , is most conveniently prepd. by a modified form of Scholvién's method for the prepn. of his "Jodphenin," to which he assigns the comp. $C_{10}H_{11}O_2N_2I_4$ (Friedländer, *Fortachr. Theerfarbenfab.* 3, 875); washed with satd. aq. I and dried on clay, it m. $133-4^\circ$; although reasonably stable in the air, it slowly becomes lighter in color and after several months, although the crystals retain their original shape, the residue consists essentially of phenacetine. The periodide I can be detd. quant. by titration with $Na_2S_2O_3$ and the total I by treating in $AcOH$ with satd. aq. SO_2 and pptg. with $AgNO_3$. The compd. affords a practical basis for the quant. sepn. of $AcNHPh$ and phenacetine and by its means as little as 0.5 mg. of the latter base can be qual. detected. *Acetanisidine hydriododide*, m. $142-3^\circ$, is the only periodide which it has thus far been possible to obtain from methacetine; it seps. in several cryst. forms and varying shades of color; as reddish brown leaflets or scales, ruby-red prisms and thick garnet prismatic plates, depending on the temp., concn. and nature of the solvent. It is identical with Piutti's " $C_{11}H_{13}O_2N_2I_4$ " (*Gazz. chim. ital.* 25, 519 (1895)). Although a tetraiodide has not been isolated, there are indications, notably certain color changes in the cryst. products before and after removal from the mother liquors, that it may exist under the proper conditions. *Propiophenetidine hydriododide*, from the base in aq. alc. with I and HI in varying proportions, greenish bronze needles, m. $121-3^\circ$; with I in $AcOH$ it gives the *tetraiodide*, purple-black silky needles, m. $92-4^\circ$.

CHAS. A. ROUILLER.

Role of atmospheric oxygen in the oxidation of glucose with potassium permanganate in the presence of varying amounts of alkali. The products of oxidation. EDGAR J. WITZEMANN. *J. Am. Chem. Soc.* 38, 150-61 (1916); cf. *C. A.* 6, 3089.—Two g. portions of glucose in 1 l. of 0-1.8 *N* KOH were completely oxidized at room temp. in the course of several weeks by adding small amts. of KMnO_4 , shaking occasionally until the KMnO_4 was reduced before adding the next portion and continuing the process until the last portion was reduced only after standing several days. The sole products of oxidation were found to be CO_2 and $(\text{CO}_2\text{H})_2$, both of which were detd. quant., and the KMnO_4 equiv. of the MnO_2 sludge was also detd. by dissolving in $(\text{CO}_2\text{H})_2\text{-H}_2\text{SO}_4$ and titrating the excess of $(\text{CO}_2\text{H})_2$ with KMnO_4 . Calcn. of the amt. of KMnO_4 which should have been used to give the amts. of oxidation products found showed that the amt. of KMnO_4 actually consumed was less than the calcd., the discrepancy increasing with increase in the KOH used. This was not due to a reduction of the KMnO_4 to a lower oxide than MnO_2 , analysis of the MnO_2 sludge showing that the KMnO_4 deficit due to this cause was very small, in no way parallel with the deficit shown by the above calcn. and moreover disappeared completely when the amt. of KOH originally used and that formed from the KMnO_4 was sufficient or more than sufficient to form the neutral salts of the oxidation products. The KMnO_4 deficit increases rapidly with increasing KOH concn. up to a soln. originally 0.114 *N* with respect to KOH and about 0.05 *N* at the end of the expt.; with further increase in concn. of the KOH the deficit markedly decreases. The deficit may be explained in 3 ways: (1) A large proportion of the MnO_2 is further reduced and subsequently oxidized back by the air to MnO_3 ; (2) the alkali serves as a catalyst in facilitating the oxidation by atm. O of the glucose and the products of its reaction with alkali; the Mn^{II} compds. may play a role in this catalysis; (3) a combination of (1) and (2). "There is nothing in the literature to indicate that (1) can be a material factor in the phenomenon, but there is much evidence for the truth of (2). Up to the soln. originally 0.0280 *N* with respect to KOH, the yields of CO_2 and $(\text{CO}_2\text{H})_2$ were 100 and 0%, resp.; in 0.042 *N* KOH, 98 and 2%; in 0.056 *N* KOH, 88 and 12%; in 0.071 *N* KOH, 72 and 28%, the amt. of $(\text{CO}_2\text{H})_2$ increasing to a max. of 42% in 1.82 *N* KOH. The 28% yield is obtained when the amt. of available KOH is sufficient to form the neutral salts of the oxidation products, so that the $(\text{CO}_2\text{H})_2$ formed is protected from further oxidation, $(\text{CO}_2\text{K})_2$ being stable towards KMnO_4 . If the observations of Smolka (*Sitzb. Akad. Wiss., Wien* 95, II, 5 (1887)), viz., that with insufficient KMnO_4 in the absence of alkali 1 mol. glucose yields 1 mol. of $(\text{CO}_2\text{H})_2$ and 4 mols. CO_2 , held true in all cases, the max. yield of $(\text{CO}_2\text{H})_2$ would be only 33%, but glucose in the presence of alkalies and absence of O undergoes changes and is finally broken up into shorter chains tending to give quant. 1 mol. $(\text{CO}_2\text{H})_2$ and 1 mol. CO_2 with strongly alk. KMnO_4 ; the amt. of $(\text{CO}_2\text{H})_2$ in excess of 33% in the above expts. with excess of alkali, may, as far as is now known, be roughly taken as a measure of the amt. of such a decompn. CHAS. A. ROUILLER.

II. BIOLOGICAL CHEMISTRY.

WILLIAM J. GIES, EDGAR G. MILLER, JR., PAUL E. HOWE.

A. GENERAL.

FRANK P. UNDERHILL.

Nephelometric study of the proteins of cerebrospinal fluids. I. Relation of englobulin, total globulin and total protein to the Wassermann reaction. J. A. F. PFEIFFER, P. A. KOBER AND C. W. FIELD. *Proc. Soc. Exp. Biol. Med.* 12, 153-7 (1915).—The results with total protein estns. show, assuming that figures above 0.05% indicated pathological increase, that 34 cases out of 51 agreed with positive Wasser-

mann reactions, while 48 out of 54 agreed with negative Wassermann reactions. Similarly, the figures for the *total globulin* estns. showed, assuming 0.02% or less as normal, that 24 cases out of 31 agreed with positive Wassermann reactions, while 44 out of 54 cases agreed with negative Wassermann reactions. The *euglobulin* content seemed to show remarkably close agreement with the Wassermann test; those above 0.004% agreed with a positive Wassermann test in 14 out of 16 cases, and those below 0.004% agreed with a negative Wassermann reaction in 33 out of 35 cases. Of these 4 discrepancies, the authors state that they had good reason to doubt the figures obtained in at least 2 cases.

V. C. M.

Thermodynamical objections to the mechanical theory of life. H. S. REDGROVE. *Chem. News* 112, 271-3(1915).—With the substitution of the theory of dynamic isomerism for that of tautomerism, a strong support for the mechanical theory of life is destroyed. Since any tautomeric substance is in equil., the mol. heat of combustion of the keto and enol forms should agree with neither that calcd. for the one form nor for the other. This is found to be the case with aldehydes and ketones; while other carbonyl containing compds., e. g., esters, acids, carbonyl sulfide, etc., give theoretical values in agreement with the observed. The laws of thermodynamics are not universally valid; they serve to distinguish the world of mechanism from the world of life. The theoretical possibility that intelligence may contravene the laws of entropy is destructive of its theoretical universality. Indeed the law of evolution is contrary to the law of increase of entropy.

R. L. SIBLEY.

Further studies on Pikelharing's pepsin. W. E. RINGER. Univ. Utrecht. *Z. physiol. Chem.* 95, 195-258(1915); cf. *C. A.* 6, 1445.—Pikelharing's pepsin has no iso-electric point; in acid soln. it is always negatively charged. Pepsin binds proteins and albumoses but not amino acids. It binds those substances upon which it exerts an enzymatic action. Such bound pepsin has an iso-electric point; but the enzyme is not completely united and the free part wanders towards the anode. The union of H and Cl ions with pepsin does not differ greatly from the union with albumoses. In dil. acid solns. more H is bound than Cl, but with increasing concn. of acid the 2 values are more nearly the same until, when 0.1 N HCl is used, the values are equal. The fact that the enzyme never moves towards the cathode may be explained by the relation of the amts. of protein and enzyme or by the supposition that in acid medium the compd. is completely dissociated or nearly so. That pepsin possesses a flocculation optimum is also probably due to the protein component. Either the enzyme is bound to the protein at this point or the enzyme is pptd. with the protein. The same is true of the peculiar reaction of coagulation, when the enzyme is rapidly heated in HCl soln. There is a close relation between the action of pepsin and the swelling of protein. In HCl the swelling max. is at p_H 2.5, while the optimum reactivity of pepsin is at p_H 2.1. The reaction optimum for pepsin is, in general, different in solns. of different acids. A study was made of oxalic, lactic, acetic, citric acids, HCl, H_3PO_4 , and H_2SO_4 . In concd. solns. of AcOH pepsin is inactive. Salts with strong hydrophile ions should have a greater retarding effect on peptic activity. The retardation was found to be citrate < acetate < Cl < ClO_3 < NO_3 < CNS < SO_4 .

C. J. WEST.

Compounds obtained by the decomposition of proteins by nitric acid. II. CARL TH. MÖRNER. *Z. physiol. Chem.* 95, 263-309(1915).—Earlier work (*C. A.* 9, 917) reported the isolation of methylsulfonic acid. The following compds. have been isolated from the various mother liquors: (A) oxalic acid, (B) *p*-nitrobenzoic acid, (C) benzoic acid, (D) terephthalic acid, (E) trinitrophenol. The amts. of oxalic acid isolated were (given in %): from serum protein 28.6, from egg white protein 20.9, from casein 26.5, from ovomucoid 36.8, from hemoglobin 22.5, from keratin 40.9, from glutin 28.6. The average is about 30%. Oxalic acid is destroyed by heating at 80°

with 60% HNO_3 . Results are given for various periods of heating and various concns. of acid. The amt. of oxalic acid formed by the action of varying concns. of HNO_3 upon the different amino acids was detd. Serine, cystine, tyrosine and tryptophan give from 14 to 40% acid when treated with 60% HNO_3 . When treated with HNO_3 of d. 1.50, the following %s of oxalic acid were obtained: glycocoll 11, alanine 51, valine 3, leucine 8, aspartic acid 33, glutamic acid 5, arginine 21, lysine 19, phenylalanine 3, histidine 3, proline 36, oxyproline 51, leucylglycine 15, hippuric acid 3, asparagine 28, ornithine 12. Crude *p*-nitrobenzoic acid was obtained as follows: from serum protein 1.8%, egg white protein 3.1, casein 2.1, ovomucoid 0.8, hemoglobin 2.9, keratin 1.2. The source of this acid is principally phenylalanine. It was purified as follows: 1 g. of the acid was dissolved in 6-8 cc. *N* NH_4OH , filtered, dild. to 15 cc. and 5 cc. concd. MgCl_2 soln. added, and the resulting salt recrystd. from 5 parts H_2O . Because of the ease of isolating *p*-nitrobenzoic acid it may possibly be used as a means of estg. the amt. of phenylalanine in those proteins where the amt. present is small. Ethyl acetate dissolves 2.8 g. acid per 100 cc. at 17°; H_2O , 0.013 g.; 20% HNO_3 , 0.033 g.; 30% HNO_3 , 0.039 g.; 60% HNO_3 , 0.085 g. At 100° 0.8% sublimes after 30 hrs., at 150° 16.6% after 6 hrs. The Mg salt contains 8 mols. H_2O , of which 7 are removed by drying *in vacuo* for 7 days. This salt is more insol. than the Mg salt of benzoic and the 2 isomeric mono- NO_2 acids. Only small amts. of benzoic acid are isolated from the crude *p*-nitrobenzoic acid. The amts. of terephthalic acid found were: from serum protein 0.17%, egg white protein 0.10, casein 0.07, ovomucoid 0.08, hemoglobin 0.10, keratin 0.16. The amts. of picric acid obtained were: from serum protein 0.54%, egg white protein 0.71, casein 0.81, ovomucoid 0.48, hemoglobin 0.67, keratin 0.48. The picric acid probably has its source in tyrosine, phenylalanine and, to a less extent, in tryptophan.

C. J. WEST.

Iodoprotein. ADOLF OSWALD. Zürich. *Z. physiol. Chem.* 95, 351-2(1915).—A colorless iodoprotein may be obtained by dissolving protein in alkali, cooling to 0°, adding an excess alkali and an excess of a soln. of KI-I. It is then dialyzed free of ionizable I and pptd. with dil. AcOH .

C. J. WEST.

Behavior of amino acids toward neutral salts in aqueous solution (PFEIFFER) 10.
Dental porcelains (WATTS) 19.

B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

A modification of Rose's method for the estimation of pepsin. MAURICE H. GIVENS. U. S. Pub. Health Service, Hyg. Lab., *Bull.* 101; *Am. J. Pharm.* 87, 541-9 (1915).—G. recommends the following method: Strain the gastric contents through cheesecloth. Measure 2 cc. by means of an Ostwald pipet into a 25 cc. stoppered volumetric cylinder, and dil. to the mark with distd. H_2O . Measure into each of 7 small test tubes (1 × 10 cm.) with an Ostwald pipet, 1 cc. of a 0.25% filtered pea globulin in 10% NaCl soln. Add to each tube 1 cc. of 0.6% HCl , also by means of an Ostwald pipet. Allow the tubes to stand about 5 min., until the max. turbidity develops. Add to the first 5, distd. H_2O as follows: to (1) 0.9 cc., to (2) 0.8 cc., to (3) 0.7 cc., to (4) 0.6 cc., to (5) 0.2 cc.; to (6) and (7) no H_2O . Rapidly add to each test tube the following amts. of the 1: 12.5 gastric juice, to (1) 0.1 cc., to (2) 0.2 cc., to (3) 0.3 cc., to (4) 0.5 cc., to (5) 0.8 cc., to (6) 1.0 cc., and to (7) 1.0 cc. of boiled juice. These measurements can be accurately made with a 1 cc. pipet graduated in 0.01 cc. Immerse all tubes for 15 min. in a water bath at 50 to 52°. At the end of this time, the tube is selected which is clear and contains the least amt. of dil. gastric juice. Upon this basis, the peptic activity is calcd. as the number of cc. of 0.25% globulin digested by 1 cc. of undild. gastric juice. For example, if tube (2) containing 0.3 cc.

of a 12.5 times dild. juice be clear, then the result would be expressed: Peptic activity = $12.5 (1 + 0.3) = 41.2$. W. G. GAESSLER.

An easy method of detecting *S. pallida* and other spirochetes. ALFRED C. COLES. *Brit. Med. J.* 2, 777(1915).—The method depends upon the principle that, in a medium of low refractive index, structures colored with a fluorescent dye stand in relief against a dark background. Geimsa's stain, dild. with an equal vol. of MeOH or acetone is used. A film is prepd. with the serous exudate from a primary sore. A few drops of the dild. stain are placed on the film and 10 vols. of water added at once; the film is kept in this mixt. for 10–15 min. The prepn. is observed through an 8 mm. objective and a No. 4 or 5 ocular. A dark ground is obtained by fitting an ordinary condenser with a Travis expanding stop. A paraffin lamp is used for illumination.

A. H. RAHE.

A simple method for the cultivation of anaerobic organisms. LYN DIMOND.

Brit. Med. J. 2, 778(1915).—An adaptation of Buchner's well-known method. The apparatus consists of test tubes placed as shown in the figure.

A. H. RAHE.

A practical method for estimating the protein content of cerebrospinal fluid. J. A. F. PFEIFFER. *Med. Record* 89, 66(1916).—Three cc. of a 4% soln. of sulfosalicylic acid are placed in a test tube 1 cm. in diam., and 5 cc. of spinal fluid added without mixing when, if an excess of protein is present, a white ring appears. An approx. estimate of the amt. of excess protein is obtained by comparison with a series of tubes containing a const. amt. of the reagent and varying quantities of fluid.

A. H. R.

A simple apparatus for the quantitative determination of extremely small amounts of albumin. RICHARD WEISS. *Schweiz. Apoth. Ztg.* 53, 646–7(1915); see *C. A.* 9, 3260.

S. WALDBOTT.

A new method for the production of general analgesia and anesthesia with a description of the apparatus used. D. E. JACKSON. St. Louis. *J. Lab. Clin. Med.* 1, 1–12(1915).—The method involves a continuous process of rebreathing of the gaseous or volatilized anesthetics from which the exhaled CO₂, etc., have been removed, and to which O is constantly added in suitable proportions. A description of the app. is given.

H. G. W.

Hydrogen-ion acidity. THOMAS H. KELLY. Cincinnati Gen. Hosp. *J. Lab. Clin. Med.* 1, 194–6(1915).—Discussion of the Fischer method for detg. the H-ion concn. of urine, and the method of Levy, Rowntree and Marriott for blood. Both methods were found satisfactory for clinical purposes.

Apparatus for the culture of yeast used for the determination of various sugars by fermentation (TRAMBICS) I.

C. BACTERIOLOGY.

ERNEST D. CLARK.

Studies in bacterial metabolism. XI. Observations on the proteolytic enzyme of *Bacillus proteus*. A. I. KENDALL AND A. W. WALKER. Chicago. *J. Infect. Dis.* 17,

442-53(1915).—The bacillus proteus forms a sol. proteolytic enzyme in plain broth and plain gelatin. The mature enzyme may be obtained in an active state free from bacteria by filtering the culture through sterile Berkefeld filters. The enzyme appears to be a preparatory enzyme in the sense that it prepares protein for assimilation by the bacteria; it has no role in the intracellular utilization of the protein by the bacteria. The liquefaction of the gelatin by the bacteria-free enzyme is not accomplished by the liberation of NH_3 ; deamination is an independent phenomenon associated with the intracellular utilization of the products of proteolysis by the organisms themselves. The proteolytic enzyme does not appear in an active state in media containing a utilizable carbohydrate; it appears only when protein or protein derivs. are being utilized for energy by *B. proteus*. Dextrose added to broth or gelatin cultures of *B. proteus* prevents the formation of the enzyme: under these conditions the enzyme would appear to be unnecessary for the metabolism of the bacteria, because they are acting chiefly upon the dextrose. Amts. of dextrose up to 0.3% prevent the formation of the enzyme until the sugar is exhausted; then the bacteria must utilize protein constituents of the medium for energy and consequently enzyme formation begins promptly. Larger amts. of dextrose than 0.3%, which cannot be wholly exhausted by the bacteria, permanently prevent the formation of the enzyme. It is thought that the accumulation of the products of fermentation of dextrose, principally organic acids, create environmental conditions which inhibit the metabolism of the organisms and eventually lead to their death. Dextrose in itself does not materially inhibit the activity of the mature bacteria-free enzyme; sterile dextrose gelatin is as rapidly and completely liquefied as plain gelatin. It is admitted that these observations do not preclude the possibility that conditions other than those obtaining in the expts. recorded may influence the formation of the enzyme.

JULIAN H. LEWIS.

The effects of bacterial metabolism on the antigenic properties and serologic reaction of bacteria. J. P. SIMONDS. Chicago. *J. Infect. Dis.* 17, 500-9(1915).—The immune serum produced by injecting rabbits with dead typhoid bacilli grown on dextrose media contained a higher titer of agglutinins than that produced by injecting those grown on sugar-free media. The dextrose strain is more easily agglutinated than the sugar-free strain, even with the heterologous serum. The dextrose strain was more readily engulfed by leucocytes than the sugar-free strain, even in the presence of serum immune to the sugar-free strain. But the % of leucocytes engaged in phagocytosis was greater in the presence of the homologous than of the heterologous serum. The dextrose strain is much more easily destroyed by normal serum than the sugar-free strain. The results obtained by using immune serum were very confusing and lacking in uniformity. The cause of this was found to be a variation in the amt. of lysins in different specimens of normal guinea-pig serum used as complement and in the effect of this normal lysin on the dextrose and sugar-free strains. The potency of the endotoxin of the dextrose strain was much less than that of the sugar-free strain. It is suggested that these expts. explain the favorable results reported by Coleman (*C. A.* 9, 1801) with his high calory diet in typhoid fever. The large carbohydrate component of the diet leads to a greater storage of carbohydrate in the liver and other tissues which may render the infecting strains of typhoid bacilli more susceptible to the action of the normal and immune lysins of the blood and may also reduce the potency of its endotoxin.

JULIAN H. LEWIS.

Treatment of septic wounds by continuous oxygenation or irrigation. W. A. WOOD. *Brit. Med. J.* 2, 503(1915).—A method is described for continuous oxygenation of wounds, with O under pressure of 3 or 4 lbs. The gas is enclosed in an impervious rubber bag.

A. H. RAHE.

A classification of the meningococci based on group agglutination obtained with monovalent immune rabbit sera. ARTHUR W. M. ELLIS. *Brit. Med. J.* 2, 881-4 (1915).—Agglutination tests on 46 strains of meningococci from various sources indicated that all of these belonged to one or the other of two types, according to their reaction to monovalent immune rabbit sera. A. H. RAHE.

Grouping of the strains of meningococcus. JOSEPH A. ARKWRIGHT. *Lister Inst. Brit. Med. J.* 2, 885-8 (1915).—Thirty strains of meningococci fell into 2 main groups according to results of agglutination tests. Five other strains appeared to be of intermediate type. The two main types corresponded to Dopter's classification of meningococci and parameningococci. A. H. RAHE.

Sterilization of catgut. RENÉ GUYOT. *J. pharm. chim.* 12, 152-7 (1915).—Ether is used as the antiseptic. The process is described in detail. S. WALDBOTT.

New method of detection of typhoid bacilli in stools. P. GAUTIER. *Rev. méd. de la Suisse Romande; Schweiz. Apoth. Ztg.* 53, 522-4 (1915).—The new method of Carnot and Weill-Hallé (*Presse méd.* March 25, 1915) is based on the mobility of the Eberth bacillus through a 10 cm. layer of sterilized sand contained in one arm of a U-tube. The other arm is filled with sufficient bouillon entirely to cover the sand. The bouillon is colored with neutral red, then inoculated in the part of the tube free from sand, and the app. left in the incubator at 37° for 18 hrs. The color of the liquid in the arm free from sand will then be yellow fluorescent, due chiefly to colon bacilli. The liquid above the sand is either red and slightly cloudy, indicating the presence of the mobile Eberth bacillus; or yellow, due to the likewise mobile paratyphic bacilli; or the liquid is red and clear, indicating the entire absence of the bacilli named. G. finds by 30 expts. that the method is reliable only when additional tests are made with the liquids obtained, *viz.*, agglutination of the bacilli by antityphic or antiparatyphic sera; also the prepn. of pure cultures by reinoculation. The mobility of the colon bacillus through the sand, though less than that of Eberth's, may complicate the method; also its failure, at times, to turn the color from red to yellow within 18 hrs. S. WALDBOTT.

D. BOTANY.

CARL L. ALSBERG.

Ash composition of upland rice at various stages of growth. P. L. GILE AND J. O. CARRERO. Porto Rico Agr. Exp. Sta. *J. Agr. Research* 5, 357-64 (1915).—Ash analyses of upland rice were made at intervals from early stage to complete maturity. Percentages of K_2O , P_2O_5 , and S in ash of the whole plant above ground decreased with the age of the plant, while SiO_2 increased and N in the dry matter decreased. As compared with 103 days, when the panicles were just out, the mature plant above ground at 123 days with the seeds ripe contained an equal amount of CaO , MgO , and P_2O_5 , slightly more Fe, S, Cl, N, and SiO_2 , much less Na_2O , and considerably more K_2O . Percentages of Fe in the ash of the green leaves and straw decreased regularly and markedly with the age of the plant, while the percentages of Fe in the ash of the whole plant above ground remained fairly const. after the 26-day-old sample. Previous to flowering, the percentages of dry matter in the green plant and of ash in the dry matter seemed to be influenced by the effect of the weather on the growth of the plant. W. H. FRY.

Carbohydrate transformations in sweet potatoes. HEINRICH HASSELBRING AND LON A. HAWKINS. Bureau of Plant Industry. *J. Agr. Research* 5, 543-60 (1915).—In the carbohydrate transformations in stored sweet potatoes starch is first converted to reducing sugar and cane sugar is synthesized from the reducing sugar. The rates of starch hydrolysis and of sugar synthesis in a general way conform to the van't Hoff

temp. rule for rates of chem. reactions. At high temps. the reactions are rapid at first, but soon become slower and approach an end point. At low temps. the rates are slower and the end point is so shifted as to permit a greater concn. of sugar. The reactions are continuous. In the growing sweet potato the concn. of sugar remains comparatively low. The extensive conversion of starch into sugar appears to be inhibited by the activity of the vines. When the vines are destroyed and the flow of materials to the roots is thus interrupted, the carbohydrate transformations characteristic of stored sweet potatoes are begun, even if the roots are left in the ground.

W. H. FRY.

Influence of the electric state of plants on absorption by their roots of nutritive substances from dilute solutions. D. CHOUGHAK. *Russ. J. exp. Landw.* 16, 249-69 (1915).—A very feeble elec. current was passed through wheat plants immersed in a very dil. nutrient soln. The rate of absorption of both cations and anions is thus modified. As for the cations, the rate remains const. regardless of the intensity of the current when the plants are bound to the positive pole; but when bound to the negative pole the rate increases at first very quickly, with intensity of current, up to a certain point, then increases feebly or becomes const. The inverse takes place with the anions. These variations of rate are not due to electrolysis. The increase of absorption due to increase of current intensity increases much more rapidly than the quantity of ions that increased intensity could liberate according to Faraday's law. Analogous expts. were made with dead wheat plants and similar results were obtained. This leads to the supposition that some substances of the roots, probably colloidal, become polarized, taking charges of different sign and quantity and having limiting values. These charges are directly observable when a current is not passed. If 2 Pt threads are bound to the posts of a capillary electrometer, a difference of potential is shown. This difference is modified by the addition of any salt to the liquid. This variation of potential changes the rate of absorption of cations and anions according to the same rule as the current.

W. H. FRY.

Oxidases and their inhibitors in plant tissues. IV. Flowers of iris. W. R. G. ATKINS. *Sci. Proc. Roy. Dublin Soc.* 14, 317-26(1915).—Peroxidase reactions in buds and mature flowers differ neither in distribution nor in intensity. Withered flowers gave erratic results. The stigmatic surface and central vein of the style gave well marked reactions in almost every case and in none was there a complete absence of peroxidase activity. The reactions of the enzyme in the veins and epidermis of 82 different specimens belonging to different groups towards benzidine and α -naphthol were investigated. In order to investigate the influence of light on the peroxidase activity some blossoms of iris were picked and one fall immediately examd. The flowers were then placed in total darkness with the stalks in water and after 24 hrs. a second fall was removed and the third after 66 hrs. The results showed that darkness permitted the accumulation of peroxidase in an active condition and even leads to the formation of organic peroxidases in some species. The effect increases slowly with time. Almost complete absence of peroxidase activity from flowers of a dark claret color was observed and as the pigment is produced as the result of the enzyme action, this anomaly was explained by assuming the production of an inhibitor. An attempt was made to ascertain whether yellow or blue light was the most injurious to peroxidase production but no difference was observed and the peroxidase reactions in both were more intense because of diminution of light.

R. L. SIBLEY.

The pigments of fruits in relation to some genetic experiments on *Capsicum annuum*. W. R. G. ATKINS AND G. O. SHERRARD. *Sci. Proc. Roy. Dublin Soc.* 14, 328-34(1915).—The colors of the capsicum fruits are due to pigments located in plastids

contained in the epidermis as well as in the deeper tissues. The difference in the depth of the color seemed to be due to the size or thickness of the cell wall and to the variations in packing with chromatophores. Peroxidase is most active in the unripe fruits and is probably connected with changes that take place on ripening. The action of the oxidases in the ripe fruit is largely checked by inhibitors developed in the epidermis and in all underlying cells. The age of the fruit seems to be the most important factor in deciding the degree of activity of the oxidases although the color of the fruit seemed to vary with the activity of the enzyme. No positive tests for tyrosinase were obtained. The soly. of the pigments in the different org. solvents was detd. and it was found that upon sufficient diln. the colors usually approached one another almost to the point of matching, thus proving that the pigments of an individual color were not mixts.

R. L. SIBLEY.
